2. Megjegyzés. – A Modernizált Globális Navigációs Műhold Rendszer /GLONASS-M/ ugyancsak az L2-n egy távolság meghatározó kódot fog sugározni elegendő teljesítménnyel ahhoz, hogy az összes, a föld közelében lévő olyan akadálymentes helyen, amelyről a műhold 5 fokon, vagy annál nagyobb magassági szögben észlelhető, a vett rádiófrekvenciás /RF/ jel szintjének a 3 dBi lineárisan polarizált antenna kimeneten a -167 dBW-nél nem lesz kevesebb az összes olyan antenna beállításra, amely a terjedés irányára merőleges.

3.7.3.2.5.5 *Moduláció*

3.7.3.2.5.5.1 A Globális Navigációs Műhold Rendszer /GLONASS/ műholdnak a vivőhullám frekvenciáján a navigációs rádiófrekvenciás /RF/ jelet kell kisugározni a bipoláris fázis eltolásos /BPSK/ modulációjú bináris impulzus-sorozat felhasználásával. A vivőhullám fázis eltolását a π-radiánsokkal kell elvégezni ±0,2 radián maximális hibával. Az ál-véletlen kódsorozatot minden egyes milliszekundumban meg kell ismételni.

3.7.3.2.5.5.2 A moduláló navigációs jelet a következő három bináris jel Modulo-2 összeadásával kell generálni:

a) távolság meghatározó kód 511 kbit/s-al leadva;

b) navigációs közlemény 50 bit/s-al leadva; és

c) 100 Hz-es segéd meander sorozat.

3.7.3.2.6 *Globális Navigációs Műhold Rendszer /GLONASS/ idő*. A Globális Navigációs Műhold Rendszer /GLONASS/ ideje az Egyeztetett Világidőre /UTC/ vonatkoztatott idő kell, hogy legyen (Oroszország Nemzeti Idő Szolgálata által kezelt idő).

3.7.3.2.7 *Koordináta rendszer*. A Globális Navigációs Műhold Rendszer /GLONASS/ koordináta rendszerének a PZ-90-nek kell lenni.

Megjegyzés. – A Globális Navigációs Műhold Rendszer /GLONASS/ által használt PZ-90 koordináta rendszerről a Geodéziai Világrendszer – 84 /WGS-84/ koordinátáira való átszámítás a "B"- Függelék 3.2.5.2 pontjában van meghatározva.

3.7.3.2.8 *Navigációs információ*. A műhold által leadott navigációs adatoknak azokat a szükséges információkat kell magába foglalni, amelyek meghatározzák:

a) a műhold adási idejét;

b) a műhold helyzetét;

c) a műhold 'egészségét' /működési állapotát/;

d) a műhold óra helyesbítését;

e) az Egyeztetett Világidőre /UTC/ való idő átvitelt; és

f) az állandó-pályájú műhold rendszer helyzeti állapotát.

Megjegyzés. – Az adatok szerkezete és tartalma a "B"- Függelék 3.2.1.2 és 3.2.1.3 pontjában különkülön került meghatározásra.

3.7.3.3 *Légijármű-Bázisú Kiegészítő Rendszer (ABAS)*

3.7.3.3.1 *Teljesítmény*. A Légijármű-Bázisú Kiegészítő Rendszer (ABAS) funkciói az egyéb Globális Navigációs Műhold Rendszer /GNSS/ elmeinek egyikével, vagy abból többel kombinálva, és mindkét, egy hibamentes GNSS vevővel és egy hibamentes légijármű fedélzeti rendszerrel a Légijármű-Bázisú Kiegészítő Rendszer /ABAS/ funkcióra használva meg kell, hogy feleljen a 3.7.2.4 pontban meghatározott pontossági, teljességi /integritási/, folyamatossági és elérhetőségi követelményeknek.

3.7.3.4 *Műhold-Bázisú Kiegészítő Rendszer (SBAS)*

3.7.3.4.1 *Teljesítmény*. A Műhold-Bázisú Kiegészítő Rendszer (SBAS) funkciói az egyéb Globális Navigációs Műhold Rendszer /GNSS/ elmeinek egyikével, vagy abból többel kombinálva, és egy hibamentes vevővel együtt meg kell, hogy feleljen a 3.7.2.4 pontban meghatározott pontossági, teljességi /integritási/, folyamatossági és elérhetőségi követelményeknek.

Megjegyzés. – A Műhold-Bázisú Kiegészítő Rendszer /SBAS/ kiegészíti az alap állandó-pályájú műhold rendszer(eke)t azzal, hogy növeli a szolgáltatási területen belül biztosított navigáció pontosságát, *teljességét (integritás), folyamatosságát és elérhetőségét, jellemzően magába foglalva az összetett repülőtereket is.*

3.7.3.4.2 *Funkciók*. A Műhold-Bázisú Kiegészítő Rendszernek /SBAS/ a következő funkciókból egyet, vagy többet kell teljesíteni:

a) *Távolság meghatározás*: egy kiegészítő pszeudó távolság jel egy pontossági mutatóval egy Műhold-Bázisú Kiegészítő Rendszertől /SBAS/ (3.7.3.4.2.1 és "B"- Függelék 3.5.7.2);

b) *Globális Navigációs Műhold Rendszer /GNSS/ műhold állapot*: a Globális Navigációs Műhold Rendszer /GNSS/ műhold működési állapotának /egészségének/ meghatározása és továbbítása ("B"-Függelék 3.5.7.3 pont);

c) *Alap különbségi helyesbítés*: biztosítja a Globális Navigációs Műhold Rendszer /GNSS/ műhold efemerisz /keringési pálya/ és óra helyesbítést (gyors és hosszú időtartamú), a műholdaktól történő pszeudó-távolságok méréséhez való felhasználásra ("B"-Függelék 3.5.7.4 pont); és

d) *Pontos különbségi helyesbítés*: az ionoszférikus helyesbítések meghatározása és továbbítása ("B"-Függelék 3.5.7.5).

Megjegyzés. – Amikor az összes funkció biztosítva van, akkor a Műhold-Bázisú Kiegészítő Rendszer /SBAS/ az alap állandó-pályájú műhold rendszerrel kombinálva alá tudja támasztani az indulási, az útvonal, a közelkörzeti és a megközelítési üzemeltetéseket az I. kategóriájú precíziós megközelítést is beleértve. A teljesítmény elérhető szintje a Műhold-Bázisú Kiegészítő Rendszerben /SBAS/ egyesített infrastruktúrától és az érintett földrajzi terület ionoszférikus viszonyaitól függ.

3.7.3.4.2.1 *Távolság meghatározás*

3.7.3.4.2.1.1 Az atmoszférikus hatások kizárásával a Műhold-Bázisú Kiegészítő Rendszerű /SBAS/ műholdak távolság meghatározási jelének távolság hibája nem haladhatja meg a 25 métert (95 százalék).

3.7.3.4.2.1.2 Annak a valószínűsége, hogy a távolság hiba bármely órában a 150 métert meghaladja, nem lehet több 10^{-5}-nél.

3.7.3.4.2.1.3 Annak a valószínűsége, hogy egy Műhold-Bázisú Kiegészítő Rendszerű /SBAS/ műholdtól a távolság meghatározási funkció nem betervezett leállása bekövetkezik, bármely órában nem haladhatja meg a 10^{-3}-at.

3.7.3.4.2.1.4 A távolság meghatározás változás hiba nem haladhatja meg a másodpercenkénti 2 méter (6.6 láb) /szekundumot.

3.7.3.4.2.1.5 A távolsági gyorsulás hiba nem haladhatja meg a 0,019 métert (0,06 láb) másodperc-négyzetenként /m/s^2/.

3.7.3.4.3 *Szolgáltatási terület*. A Műhold-Bázisú Kiegészítő Rendszer /SBAS/ szolgáltatási területének egy, az SBAS fedettségén belüli meghatározott olyan területnek kell lenni, ahol a Műhold-Bázisú Kiegészítő Rendszer /SBAS/ kielégíti a 3.7.4.2 pont követelményeit és alátámasztja a megfelelő jóváhagyott üzemeltetéseket.
1. Megjegyzés. – A fedettségi terület az a terület, amelyen belül a Műhold-Bázisú Kiegészítő Rendszerű /SBAS/ műhold adását venni lehet (például a geostacionáris 'műhold-lábnyomok').

2. Megjegyzés. – A Műhold-Bázisú Kiegészítő Rendszerű /SBAS/ műhold fedettségi és szolgáltatási területe a "D"- Melléklet 6.2 pontjában kerül megtárgyalásra.

3.7.3.4.4 *Rádiófrekvenciás /RF/ jellemzők*

Megjegyzés. – A részletes Rádiófrekvenciás /RF/ jellemzők a "B"- Függelék 3.5.2 pontjában kerültek meghatározásra.

3.7.3.4.4.1 *Vivőhullám frekvencia*. A vivőhullám frekvenciának az 1575,42 MHz-nek kell lenni.

Megjegyzés. – 2005. után, amikor a felső GLONASS frekvenciák kiürítésre kerülnek, más típusú Műhold Bázisú Kiegészítő Rendszer /SBAS/ kerülhet bevezetésre, amely ezeknek a frekvenciáknak egy részét használja fel.

3.7.3.4.4.2 *Jel spektrum*. A sugárzás teljesítményének legkevesebb a 95 százalékát az L1 frekvenciához központosított ±12 MHz-es sávnak kell magába foglalnia. Az egy Műhold-Bázisú Kiegészítő Rendszer /SBAS/ által továbbított jel sávszélességének legalább 2,2 MHz-nek kell lenni.

3.7.3.4.4.3 *Jel teljesítmény szint*. Az egyes Műhold-Bázisú Kiegészítő Rendszerű /SBAS/ műholdaknak olyan navigációs jelet kell kisugározniuk, amelynek elegendő teljesítményűnek kell lenni ahhoz, hogy az összes, a föld közelében lévő olyan akadálymentes helyen, amelyről a műhold 5 fokon, vagy annál nagyobb magassági szögben észlelhető, a vett rádiófrekvenciás /RF/ jel szintjének a 3 dBi lineárisan polarizált antenna kimeneten a -161 dBW-tól a -153 dBW-ig terjedő tartományon belül legyen az összes olyan antenna beállításra, amely a terjedés irányára merőleges.

.7.3.4.4.4 *Polarizáció*. . A sugárzott rádiófrekvenciás /RF/ jelnek jobbra-forgó (az óramutató járásával megegyező) körkörösen polarizáltnak kell lenni.

3.7.3.4.4.5 *Moduláció*. A leadott kódsorozatnak másodpercenként 500 jel sebességű navigációs közleménynek és az 1023 bit-es ál-véletlen zaj kód Modulo-2-es összeadásának kell lenni. Ezt kell azután bináris fázis eltolással modulálni /BPSK/ a vivőhullámra egy másodpercenkénti 1,023 megachip-es sebességgel.

3.7.3.4.5 *A Műhold-Bázisú Kiegészítő Rendszerű /SBAS/ hálózat idő (SNT).* A Műhold-Bázisú Kiegészítő Rendszerű /SBAS/ hálózat idő (SNT) és a Globális Helymeghatározó Rendszer /GPS/ ideje közötti különbség nem haladhatja meg az 50 nano-szekundumot.

3.7.3.4.6 *Navigációs információ*. A műholdak által leadott navigációs adatoknak azokat a szükséges információkat kell magukba foglalniuk, amelyek meghatározzák:

a) A Műhold-Bázisú Kiegészítő Rendszerű /SBAS/ műhold adási idejét;

b) A Műhold-Bázisú Kiegészítő Rendszerű /SBAS/ műhold helyzetét;

c) A helyesbített műhold időt az összes műholdra;

d) A helyesbített műhold helyzetet az összes műholdra;

e) Az ionoszférikus terjedési késés hatásait;

f) A felhasználó helyzeti integritását;

g) Az Egyesített Világidőre /UTC/ való idő átvitelt; és

h) A szolgáltatási szint állapotát.

Megjegyzés. – Az adatok szerkezete és tartalma a "B"- Függelék 3.5.3 és 3.5.4 pontjában külön-külön került meghatározásra.

3.7.3.5 Föld-Bázisú Kiegészítő Rendszer (GBAS) és Föld-Bázisú Regionális Kiegészítő Rendszer (GRAS)

1. Megjegyzés. – Ahol nincs külön magyarázattal ellátva, ott a Föld-Bázisú Kiegészítő Rendszer (GBAS) Szabványok és Ajánlott Gyakorlatok (SARPs) a Föld-Bázisú Kiegészítő Rendszerre (GBAS) és a Föld-Bázisú Regionális Kiegészítő Rendszerre (GRAS) is vonatkoznak.

2. Megjegyzés. - Ahol nincs külön magyarázattal ellátva, ott a megközelítés függőleges vezetéssel (APV) utalás APV-I és APV-II - t jelent.

3.7.3.5.1 *Teljesítmény.* A Föld-Bázisú Kiegészítő Rendszer /GBAS/ funkciói az egyéb Globális Navigációs Műhold Rendszer /GNSS/ elmeinek egyikével, vagy abból többel, valamint egy hibamentes vevővel együtt kombinálva a teljesítmény meg kell, hogy feleljen a 3.7.2.4 pontban meghatározott pontossági, folyamatossági, elérhetőségi és teljességi /integritási/ követelményeknek.

Megjegyzés. – A Föld-Bázisú Kiegészítő Rendszer /GBAS/ arra a célra szolgál, hogy alátámassza a megközelítési, leszállási, felszállási és földi mozgási üzemeltetések minden típusát és támogathatja az útvonal és közelkörzeti üzemeltetéseket. A Föld-Bázisú Regionális Kiegészítő Rendszer /GRAS/ arra a célra szolgál, hogy alátámassza az útvonal, a közelkörzeti, a nem precíziós megközelítési, a felszállási és a megközelítés függőleges vezetéssel (APV) üzemeltetéseket. A következő Szabványok és Ajánlott Gyakorlatok /SARPs/ az I. kategóriájú precíziós megközelítési, megközelítés függőleges vezetéssel (APV) és a Föld-Bázisú Kiegészítő Rendszer (GBAS) helymeghatározási szolgáltatás biztosításának alátámasztására kerültek kidolgozásra. Annak érdekében, hogy az üzemeltetések közötti működőképesség és a lehetséges hatékonyágú spektrum felhasználás elérésre kerüljön, az a cél, hogy az adattovábbítás az összes üzemeltetési kategóriára azonos legyen.

3.7.3.5.2 *Funkciók.* A Föld-Bázisú Kiegészítő Rendszernek /GBAS/ a következő funkciókat kell elvégeznie:

a) Biztosítani a helyileg érvényes pszeudo-távolság helyesbítéseket;

b) Biztosítani a Föld-Bázisú Kiegészítő Rendszer /GBAS/ vonatkozású adatokat;

c) Biztosítani a végső megközelítési szakasz adatait, amikor precíziós megközelítést támogat;

d) Biztosítani az előre kiszámított távolság meghatározási forrás rendelkezésre álló adatait; és

e) Biztosítani a Globális Navigációs Műhold Rendszer /GNSS/ távolság meghatározási forrásának integritás ellenőrzését.

Megjegyzés. – További Föld-Bázisú Kiegészítő Rendszer /GBAS/ Szabványok és Ajánlott Gyakorlatok /SARPs/ kerülnek majd kidolgozásra a földi-bázisú távolság meghatározási funkció biztosításához.

3.7.3.5.3 *Fedettség*

3.7.3.5.3.1 *I. kategóriájú precíziós megközelítési és megközelítés függőleges vezetéssel (APV).* A Föld-Bázisú Kiegészítő Rendszer /GBAS/ fedettségének az egyes I. kategóriájú precíziós megközelítési, vagy megközelítés függőleges vezetéssel üzemeltetések alátámasztásához a következőknek kell lenni, kivéve azt, ahol a földfelszíni jellemzők szabják meg és az üzemeltetési követelmények megengedik:

a) Oldalirányban, a leszállási küszöb pontjának / a látszólagos küszöb pontjának (LTP/FTP) mindkét oldalától 140 m-re (450 láb) kezdődően és a végső megközelítési útvonal mindkét oldalán ±35 fokkal kiterjedően 28 km-ig (15 tengeri mérföld) és a végső megközelítési útvonal mindkét oldalán ±10 fokkal kiterjedően 37 km-ig (20 tengeri mérföld); és

b) Függőlegesen, az oldalirányú területen belül 7 foknál nagyobb magasságig, vagy a közzétett siklópálya szög (GPA) 1,75-szereséig azon vízszintes sík felett, amelynek a kiinduló pontja a Siklópálya Befogási Pontjánál (GPIP) van és 0,45 Siklópálya Szögig /GPA/ a vízszintes felett, vagy az olyan alacsonyabb szögig lefelé, ami 0,30 Siklópálya Szög /GPA/, ahogy szükséges ahhoz, hogy védelmezze a közzétett siklópálya befogási eljárást. Ezt a fedettséget kell alkalmazni a 30 m (100 láb) és a 3000 m (10000 láb) közötti küszöb feletti magasságban /HAT/.

Megjegyzés. –A Leszállási Küszöb Pont / Látszólagos Küszöb Pont (LTP/FTP) és a Siklópálya Befogási Pont (GPIP) a "B"- Függelék 3.6.4.5.1 pontjában került meghatározásra.

3.7.3.5.3.1.1 **Ajánlás**. – *Az I. kategóriájú precíziós megközelítésnél a 3.7.3.5.4 pontban meghatározott adatsugárzást ki kell terjeszteni 3,7m-re (12 lábra) a futópálya felszíne felett.*

3.7.3.5.3.1.2 **Ajánlás**. – *Az adatsugárzás körkörös legyen, ha szükség van a tervezett alkalmazások támogatására.*

Megjegyzés. - Az I. kategóriájú precíziós megközelítéshez és a megközelítés függőleges vezetéssel (APV) szolgáltatásához szükséges fedettségre vonatkozó útmutató anyagát a "D"- Melléklet 7.3 pontja adja meg.

3.7.3.5.3.2. *A Föld-Bázisú Kiegészítő Rendszer /GBAS/ helymeghatározási szolgáltatás*.
A Föld-Bázisú Kiegészítő Rendszer /GBAS/ helymeghatározási szolgáltatás területének annak a területnek kell lennie, ahol az adatsugárzást lehet venni és a helymeghatározási szolgáltatás megfelel a 3.7.2.4 pont követelményeinek, valamint támogatja a megfelelően jóváhagyott üzemeltetéseket.

Megjegyzés. – A helymeghatározási szolgáltatással kapcsolatos fedettségre vonatkozó útmutató anyagot a "D"- Melléklet 7.3 pontja adja meg.

3.7.3.5.4 *Adatsugárzási jellemzők*

Megjegyzés. – A részletes rádiófrekvenciás /RF/ jellemzők a "B"- Függelék 3.6.2 pontjában kerültek meghatározásra.

3.7.3.5.4.1 *Vivőhullám frekvencia*. Az adatsugárzásra használatos rádiófrekvenciákat a 108-tól a 117,975 MHz-ig terjedő sáv rádiófrekvenciáiból kell kiválasztani. A legalacsonyabb kiosztható frekvenciának a 108,25 MHz-nek kell lenni, és a legmagasabb kiosztható rádiófrekvencia a 117,950 MHz kell, hogy legyen. A kiosztható frekvenciák közötti elkülönítés (csatorna-távolság) 25 kHz kell, hogy legyen.

1. Megjegyzés. – A VOR/GBAS frekvencia kiosztásra és a földrajzi elkülönítési követelményekre vonatkozó útmutató anyag a "D"- Melléklet 7.2.1 pontjában került megadásra.

2. Megjegyzés. – Az ILS/GBAS földrajzi elkülönítési követelmények és a GBAS és a 118 – 137 MHz-es sávban működő VHF rádióösszeköttetési szolgálatok földrajzi elkülönítési követelményei kidolgozás alatt állnak. Addig, amíg ezek a követelmények meghatározásra és Szabványok és Ajánlott Gyakorlatokba történő foglalásra nem kerülnek, az előirányzat az, hogy a 112,050 – 117,900 MHz-es sáv frekvenciái kerülnek felhasználásra.

3.7.3.5.4.2 *Hozzáférési technika*. Egy időosztásos többszörös hozzáférésű technikát (TDMA) kell alkalmazni egy állandó keretű felépítéssel. Az adatsugárzást egytől nyolcig terjedő résekre (slot) kell kijelölni.

Megjegyzés. – A két rés a névleges kijelölés. Bizonyos Földi-Bázisú Kiegészítő Rendszerű /GBAS/ berendezésekhez, amelyek többszörös VHF adatsugárzású (VDB) átviteli antennákat használnak, a

VHF adat-sugárzás (VDB) fedésterületének növeléséhez szükség lehet kettőnél több idő-rés kijelölésére. A többszörös antennák alkalmazására vonatkozó útmutató anyag a "D"- Melléklet 7.12.3 pontjában került megadásra; néhány Földi-Bázisú Kiegészítő Rendszerű /GBAS/ berendezés egy Föld-Bázisú Regionális Kiegészítő Rendszerben /GRAS/ használhat egy idő-rést.

3.7.3.5.4.3 *Moduláció*. A Földi-Bázisú Kiegészítő Rendszer /GBAS/ adatait 3 bites szimbólumként kell kisugározni, az adatsugárzó vivőhullámot a D8PSK-val modulálva másodpercenkénti 10 500 szimbólumos sebességgel.

3.7.3.5.4.4 *Az adatsugárzás rádiófrekvenciás /RF/ térerőssége és polarizációja*.

Megjegyzés. - A Földi-Bázisú Kiegészítő Rendszer /GBAS/ a VHF adatsugárzást biztosítani tudja vagy a vízszintes (GBAS/H), vagy az ellipszis alakú (GBAS/E) polarizációval, amely felhasználja mindkettőt, a vízszintes polarizációs (HPOL) és a függőleges polarizációs (VPOL) összetevőket. Egy függőleges polarizációjú (VPOL) összetevőt felhasználó légijármű nem lesz képes az üzemeltetés lefolytatására GBAS/H berendezéssel. A vonatkozó útmutató anyag a "D"- Melléklet 7.1 pontjában került megadásra.

3.7.3.5.4.4.1 *Földi-Bázisú Kiegészítő Rendszer / Vízszintes polarizáció /GBAS/H/*

3.7.3.5.4.4.1.1 Egy vízszintesen polarizált jelet kell kisugározni.

3.7.3.5.4.4.1.2 A kisugárzott teljesítménynek (ERP) egy vízszintesen polarizált jelet kell biztosítani egy 215 mikrovolt/méter (-99 dBW/négyzetméter) maximális térerővel és egy maximum 0,350 volt/méter (-35 dBW/négyzetméter) maximális térerővel a Földi-Bázisú Kiegészítő Rendszer /GBAS/ fedésterületén. A térerősséget egy átlagként kell mérni a szinkronizáció periódusán és a szinkron vezérjel bizonytalanság feloldási mező időtartamán át. A rádiófrekvenciás /RF/ fázis-eltolás a Vízszintes Polarizáció /HPOL/ és bármilyen Függőleges Polarizációjú /VPOL/ összetevő között olyan kell, hogy legyen, hogy a "B"- Függelék 3.6.8.2.2.3 pontjában meghatározott vízszintes jel teljesítmény megérkezzen a fedésterület minden részében a Vízszintes Polarizációjú /HPOL/ felhasználókhoz.

3.7.3.5.4.4.2 *Föld-Bázisú Kiegészítő Rendszer / Ellipszis polarizáció /GBAS/E/*

3.7.3.5.4.4.2.1 **Ajánlás.** – *Egy ellipszis polarizációjú jelet kell kisugározni, ahányszor csak megvalósítható.*

3.7.3.5.4.4.2.2 Amikor egy ellipszis polarizációjú jel kerül kisugárzásra, akkor a vízszintesen polarizált összetevőnek meg kell felelnie a 3.7.3.5.4.4.1.2 pontban meghatározott követelményeknek és a kisugárzott teljesítménynek (ERP) egy vízszintesen polarizált jelet kell biztosítani egy 136 mikrovolt/méter (-103 dBW/m^2) maximális térerővel és egy maximum 0,221 volt/méter (-39 dBW/m^2) maximális térerővel a Földi-Bázisú Kiegészítő Rendszer /GBAS/ fedésterületén belül. A térerősséget egy átlagként kell mérni a szinkronizáció periódusán és a szinkron vezérjel bizonytalanság feloldási mező időtartamán át. A rádiófrekvenciás /RF/ fáziseltolás a Vízszintes Polarizáció /HPOL/ és a Függőleges Polarizációjú /VPOL/ összetevő között olyan kell, hogy legyen, hogy a "B"- Függelék 3.6.8.2.2.3 pontjában meghatározott vízszintes jel teljesítmény megérkezzen a fedésterület minden részében a Vízszintes Polarizációjú /HPOL/ és a Függőleges Polarizációjú /VPOL/ felhasználókhoz.

Megjegyzés. – A minimális és maximális térerők a 3.7.3.5.4.4.1.2 és 3.7.3.5.4.4.2.2 pontban összhangban vannak egy -87 dBm minimális vevő érzékenységgel és a 200 méteres (660 láb) minimális távolsággal az adó antennától a 43 km (23 tengeri mérföld) fedettségi tartományra.

3.7.3.5.4.5 *A szomszédos csatornákban kisugárzott teljesítmény*. A sugárzás során a teljesítmény mennyiség minden üzemeltetési körülmény esetén, amikor egy, az i-edik szomszédos csatornán központosuló 25 kHz-es sávszélességen mérik, nem haladhatja meg a 3.7.3.5-1 táblázatban (a 3.7 pont alatti rész végén került elhelyezésre) bemutatott szinteket.

3.7.3.5.4.6 *Nem-kívánt sugárzások*. A nem-kívánt sugárzások – beleértve a hamis és a sávon kívüli sugárzásokat is – meg kell, hogy feleljenek a 3.7.3.5-2 táblázatban (a 3.7 pont alatti rész végén került elhelyezésre) bemutatott értékeknek. A teljes teljesítmény bármelyik VDB harmonikusban, vagy nem-folytonos jelben nem lehet -53 dBm-nél nagyobb.

3.7.3.5.5 *Navigációs információ*. A Föld-Bázisú Kiegészítő Rendszer /GBAS/ által kisugárzott navigációs adatoknak a következő információkat kell magukba foglalni:

a) Pszeudo-távolság helyesbítések, referencia idő és teljességi /integritás/ adatok;

b) A Föld-Bázisú Kiegészítő Rendszerhez /GBAS/ kapcsolódó adatok;

c) A végső megközelítési szakasz adatai, amikor a precíziós megközelítést támogatja; és

d) A kiszámított távolság meghatározási forrás rendelkezésre álló adatai.

Megjegyzés. – Az adatok szerkezete és tartalma a ”B”- Függelék 3.6.3 pontjában került meghatározásra.

3.7.3.6 *Légijármű fedélzeti Globális Navigációs Műhold Rendszer /GNSS/ vevő*

3.7.3.6.1 A légijármű fedélzeti Globális Navigációs Műhold Rendszer /GNSS/ vevőjének azon Globális Navigációs Műhold Rendszerek elemeinek az adatait kell feldolgozni, amelyeket fel akar használni úgy, ahogy az a ”B”- Függelék 3.1 pontjában (a Globális Helymeghatározó Rendszerre /GPS/), a ”B”- Függelék 3.2 pontjában (a Globális Helymeghatározó Rendszerre /GLONASS/), a ”B”- Függelék 3.3 pontjában (a kombinált GPS és GLONASS-ra), a ”B”- Függelék 3.5 pontjában (a Műhold-Bázisú Kiegészítő Rendszerre /SBAS/) és a ”B”- Függelék 3.6 pontjában (a Föld-Bázisú Kiegészítő Rendszerre /GBAS/, valamint a Föld-Bázisú Regionális Kiegészítő Rendszerre /GRAS/) meghatározásra került.

3.7.4 Az interferenciával szembeni ellenállás

3.7.4.1 A Globális Navigációs Műhold Rendszernek /GNSS/ teljesítenie kell a 3.7.2.4 pontban és a ”B”- Függelék 3.7 pontjában meghatározott teljesítmény követelményeket a ”B”- Függelék 3.7 pontjában meghatározott interferencia környezet fennállása esetén.

Megjegyzés. – A GPS és a GLONASS helymeghatározó rendszerek az 1559 – 1610 MHz-es frekvenciasávban üzemelnek, amelyet a Nemzetközi Távközlési Egyesület /ITU/ úgy osztályozott, hogy az a rádiónavigációs műholdas szolgáltatás (RNSS) és a légiforgalmi rádiónavigációs szolgáltatás (ARNS) frekvenciája, és speciális spektrum védelmi helyzetet biztosított a rádiónavigációs műholdas szolgáltatás /RNSS/ részére. Annak érdekében, hogy elérésre kerüljenek azok a teljesítmény célok, hogy a precíziós megközelítések irányvezetése a Globális Navigációs Műhold Rendszerrel /GNSS/ és kiegészítőivel alátámasztásra kerüljön, a rádiónavigációs műholdas szolgáltatás/légiforgalmi rádiónavigációs szolgáltatás /RNSS/ARNS/ előirányzottan marad a globális kijelölés szerint csak az 1559 – 1610 MHz-es sávban, és az ezzel szomszédos frekvenciasávban működő rendszerek sugárzását akarják keményen ellenőriztetni a nemzeti és/vagy nemzetközi előírásokkal.

3.7.5 Adatbázis

Megjegyzés. – A légiforgalmi adatokra alkalmazható Szabványokat és Ajánlott Gyakorlatokat az Annex 4, az Annex 11, az Annex 14 és az Annex 15 adja meg.

3.7.5.1 Annál a Légijármű GNSS /Globális Navigációs Műhold Rendszerű/ berendezésnél, amely egy adatbázist használ, egy eszközt kell biztosítani ahhoz, hogy:

a) Felfrissítse az elektronikus navigációs adatbázist; és

b) Meghatározza a légiforgalmi adatbázis Légiforgalmi Tájékoztató Közlemények Szabályozott Kiadási Rendszerének (AIRAC) érvényességi dátumait.

Megjegyzés. – Az egy légijármű fedélzeti Globális Navigációs Műhold Rendszerű berendezés /GNSS/ jelenleg szükséges navigációs adatbázisára vonatkozó útmutató anyag a ”D”- Melléklet 11. pontjában került megadásra.

3.7.6 Állapot ellenőrzés és NOTAM

3.7.6.1 A Globális Navigációs Műhold Rendszer /GNSS/ űrbeli és földi alkotóelemeinek olyan jelenlegi és tervezett változásait, amelyek hatással lehetnek a felhasználó teljesítményére, vagy üzemeltetési hozzájárulásaira, jelenteni kell a megfelelő légiforgalmi szolgálati egységnek.

1. Megjegyzés. – Kiegészítő tájékoztatást a ”D”- Melléklet 9. pontja biztosít.

2. Megjegyzés. – Az állapotban történt változások üzemeltetési hatásának megállapításához egy szolgáltatás előrejelzési eszközre lehet szükség.

3.7.2.4-1 táblázat: Térbeli-jel teljesítmény követelmények

Jellemző üzemeltetés	Pontosság vízszintesen 95% (1. és 3. megjegyzés)	Pontosság függőlegesen 95% (1. és 3. megjegyzés)	Teljesség (integritás) (2. megjegyzés)	Idő a riasztásig (3. megjegyzés)	Folytonosság (4. megjegyzés)	Elérhetőség (5. megjegyzés)
Útvonal	3,7km (2,0 tengeri mérföld) (6. megjegyzés)	nem alkalmazható	1-1 x 10^{-7}/h	5 perc	1-1 x 10^{-4}/h-tól 1-1 x 10^{-8}/h-ig	0,99-től 0,99999-ig
Útvonal, közelkörzet	0,74km (0,4 tengeri mérföld)	nem alkalmazható	1-1 x 10^{-7}/h	15 másodperc	1-1 x 10^{-4}/h-tól 1-1 x 10^{-8}/h-ig	0,99-től 0,99999-ig
Kezdeti megközelítés, Közbenső megközelítés, Nem-precíziós megközelítések (NPA), Indulás	220m (720 láb)	nem alkalmazható	1-1 x 10^{-7}/h	10 másodperc	1-1 x 10^{-4}/h-tól 1-1 x 10^{-8}/h-ig	0,99-től 0,99999-ig
Megközelítési üzemeltetések függőleges vezetéssel (APV-I)	16,0m (52 láb)	20m (66 láb)	1-2 x 10^{-7} megközelítésenként	10 másodperc	1-8 x 10^{-6} minden 15 másodpercben	0,99-től 0,99999-ig
Megközelítési üzemeltetések függőleges vezetéssel (APV-II)	16,0m (52 láb)	8,0m (26 láb)	1-2 x 10^{-7} megközelítésenként	6 másodperc	1-8 x 10^{-6} minden 15 másodpercben	0,99-től 0,99999-ig
I. kategóriájú precíziós megközelítés (8. megjegyzés)	16,0m (52 láb)	6,0m-től 4,0m-ig (20-tól 13 lábig) (7. megjegyzés)	1-2 x 10-7 megközelítésenként	6 másodperc	1-8 x 10^{-6} minden 15 másodpercben	0,99-től 0,99999-ig

MEGJEGYZÉSEK. –

1. A 95-ik százalékosztály értékek a Globális Navigációs Műhold Rendszer /GNSS/ helymeghatározási hibáira vonatkoznak, azokra, amelyek a futópálya küszöbe feletti legalacsonyabb magasságig (HAT) tervezett üzemeltetésekhez szükségesek, ha alkalmazható.
A részletes követelmények a ”B”- Függelékben kerültek meghatározásra, és útmutató anyagot ad még a ”D”- Melléklet 3.2 pontja.

2. A teljességi /integritás/ követelmények meghatározása magába foglal egy riasztási határértéket, amellyel szemben a követelményt meg lehet állapítani. Ezek a riasztási határértékek a következők:

Az I. kategóriájú precíziós megközelítések függőleges határértékeinek tartománya a függőleges pontossági követelmények tartományára vonatkozik.

Jellemző üzemeltetés	Vízszintes riasztási határérték	Függőleges riasztási határérték
Útvonal (óceáni / kontinentális, kis forgalom sűrűségű	7,4km (4 tengeri mérföld)	nem alkalmazható
Útvonal (kontinentális)	3,7km (2 tengeri mérföld)	nem alkalmazható
Útvonal, Közelkörzeti	1,85km (1 tengeri mérföld)	nem alkalmazható
Nem-precíziós megközelítések (NPA)	556m (0,3 tengeri mérföld)	nem alkalmazható
Megközelítési üzemeltetések függőleges vezetéssel (APV-I)	40m (130 láb)	50m (164 láb)
Megközelítési üzemeltetések függőleges vezetéssel (APV-II)	40m (130 láb)	20m (66 láb)
I. kategóriájú precíziós megközelítés	40m (130 láb)	15,0m-től 10,0m-ig (50 lábtól 33 lábig)

3. A pontossági és az 'idő-a-riasztásig' követelmények magukba foglalják egy hibamentes vevő névleges teljesítményét.

4. Értéktartományok kerültek megadásra az útvonal, a közelkörzeti, a kezdeti megközelítési, a nem-precíziós megközelítési /NPA/ és az indulási üzemeltetések folyamatossági követelményére, mivel ez a követelmény számos tényező függvénye – beleértve a tervezett üzemeltetést, a forgalom sűrűségét, a légtér összetettségét és az alternatív navigációs berendezések rendelkezésre állását. A megadott alacsonyabb érték a minimális követelmény az olyan területekre, ahol alacsony a forgalom sűrűsége és a légtér összetettsége. A megadott magasabb érték az olyan területekre alkalmas, amelyekben nagy a forgalom sűrűség és bonyolult a légtér összetettsége (lásd a "D"- Melléklet 3.4 pontját).

5. Értéktartományok kerültek megadásra az elérhetőségi követelményekre, mivel ezek a követelmények az üzemeltetési szükségek függvénye, ami számos tényezőn alapszik, beleértve az üzemeltetés gyakoriságát, az időjárási környezetet, a kényszerkiesések nagyságát és időtartamát, az alternatív navigációs berendezések rendelkezésre állását, a radar lefedettséget, a forgalomsűrűséget és az ebből eredő üzemeltetési eljárásokat. A megadott alacsonyabb értékek azok a minimális használhatósági fok értékek, amelyeknél a rendszert gyakorlatilag hasznosnak véljük., de nem elegendőnek ahhoz, hogy a nem-Globális Navigációs Műhold Rendszer navigációs berendezéseket helyettesítse. Az útvonalnavigációra a megadott magasabb értékek kielégítők ahhoz, hogy a Globális Navigációs Műhold Rendszer legyen csak egy területen belül a navigációs berendezés. A megközelítésekre és az indulásokra a magasabb értékek vannak megadva, és ezek olyan repülőtereken való használhatósági követelményekre alapozottak, amelyeken nagy a forgalom, feltételezve a több futópályára-futópályáról történő üzemeltetést, de ehhez kapcsolódóan üzemeltetési eljárások biztosítják az üzemeltetések biztonságát (lásd a "D"- Melléklet 3.5 pontját).

6. Ez a követelmény jóval szigorúbb annál, mint amilyen pontosság a társított Megkívánt Navigációs Teljesítményhez /RNP/ szükséges, de ez jóval beljebb van azon a pontossági teljesítményen, ami a Globális Navigációs Műhold Rendszerrel /GNSS/ elérhető.

7. Az értéktartományok az I. kategóriájú precíziós megközelítésre vannak meghatározva. A 4,0 méteres (13 láb) követelmény az ILS előírásokon alapszik, és egy konzervatív levezetést jelent ezekből az előírásokból (lásd a "D"- Melléklet 3.2.7 pontját).

8. A GNSS-nek a II. és III. kategóriájú precíziós megközelítési üzemeltetésekre vonatkozó teljesítmény követelményei felülvizsgálat alatt állnak, és egy későbbi dátummal kerülnek majd az anyagba beépítésre.

9. A Megközelítési üzemeltetések függőleges vezetéssel APV-I. és APV-II. kifejezések a függőleges vezetéses megközelítési és leszállási üzemeltetések két különböző szintjére utalnak, és nem szükségszerűen üzemeltetési alkalmazásra szántak.

3.7.3.5-1 táblázat: Föld-Bázisú Kiegészítő Rendszer /GBAS/ szomszédos csatornákba sugárzott adási teljesítménye

Csatorna	Relatív teljesítmény	Maximális teljesítmény
1. szomszédos csatorna	-40 dBc	12 dBc
2. szomszédos csatorna	-65 dBc	-13 dBc
4. szomszédos csatorna	-74 dBc	-22 dBc
8. szomszédos csatorna	-88,5 dBc	-36,5 dBc
16. szomszédos csatorna	-101,5 dBc	-49,5 dBc
32. szomszédos csatorna	-105 dBc	-53 dBc
64. szomszédos csatorna	-113 dBc	-61 dBc
76. szomszédos csatorna és azon túl	-115 dBc	-63 dBc

MEGJEGYZÉSEK. -

1. A maximális teljesítményt akkor alkalmazzák, ha az engedélyezett adó teljesítmény meghaladja a 150 W-ot.

2. Az egyes szomszédos pontok között, amelyeket a fentiekben megállapított szomszédos csatornák jelöltek ki, az összefüggés lineáris.

3.7.3.5-2 táblázat: A Föld-Bázisú Kiegészítő Rendszer /GBAS/ adásának nem-kívánt sugárzása

Frekvencia	Relatív nem-kívánt sugárzási szint (2. megjegyzés)	Maximális nem-kívánt sugárzási szint (1. megjegyzés)
9 kHz-től 150 kHz-ig	-93 dBc (3. megjegyzés)	-55 dBm/1 kHz
150 kHz-től 30 MHz-ig	-103 dBc (3. megjegyzés)	-55 dBm/10 kHz
30 MHz-től 106,125 MHz-ig	-115 dBc	-57 dBm/100 kHz
106,425 MHz	-113 dBc	-55 dBm/100 kHz
107,225 MHz	-105 dBc	-47 dBm/100 kHz
107,625 MHz	-101,5 dBc	-53,5 dBm/10 kHz
107,825 MHz	-88,5 dBc	-40,5 dBm/10 kHz
107,925 MHz	-74 dBc	-36 dBm/1 kHz
107,975 MHz	-65 dBc	-27 dBm/1 KHz
118,000 MHz	-65 dBc	-27 dBm/1 KHz
118,050 MHz	-74 dBc	-36 dBm/1 KHz
118,150 MHz	-88,5 dBc	-40,5 dBm/10 KHz
118,350 MHz	-101,5 dBc	-53,5 dBm/10 KHz
118,750 MHz	-105 dBc	-47 dBm/100 KHz
119,550 MHz	-113 dBc	-55 dBm/100 KHz
119,850 MHz-től 1 GHz-ig	-115 dBc	-57 dBm/100 KHz
1 GHz-től 1,7 GHz-ig	-115 dBc	-47 dBm/1 KHz

MEGJEGYZÉSEK. –

1. A maximális nem-kívánt sugárzási szintet (abszolút teljesítményszint) akkor alkalmazzák, ha az engedélyezett adó teljesítmény meghaladja a 150 W-ot.

2. A relatív nem-kívánt sugárzási szintet úgy kell kiszámítani, hogy ugyanazt a sávszélességet használják a megkívánt és a nem-kívánt jelekre. Ez szükségessé teheti a nem-kívánt jelek mérésének átszámítását, ha úgy végzik, hogy az ebben a táblázatban lévő, a maximális nem-kívánt sugárzási szint oszlopban jelzett sávszélességet használják fel.

3. Ez az érték mérési korlátozásokkal van túlterhelve. A tényleges teljesítmény várhatóan jobb lesz.

4. Az egyes szomszédos pontok között, amelyeket a fentiekben megállapított szomszédos csatornák jelöltek ki, az összefüggés lineáris.

3.8 (Fenntartva)

3.9 A fedélzeti automatikus rádióiránymérő (ADF) vevő rendszerek rendszer jellemzői

3.9.1 Az iránymérés kijelzésének pontossága

3.9.1.1 Az automatikus rádióiránymérő (ADF) rendszer által adott iránymérésben nem lehet plusz, vagy mínusz 5 foknál nagyobb hiba olyan - bármely irányból vett - rádiójel mellett, amelynek a térerőssége 70 mikro-volt/méter, vagy annál nagyobb, és amelyet az ezen Annex előírásai szerint megengedett tűréshatárokon belül működő hosszúhullámú/középhullámú irányítatlan (körkörös) sugárzású rádióadó (LF/MF NDB), vagy hely-jeladó sugároz ki, és a megkívánt jeltől 90 fokos iránnyal eltérő nem-kívánt jel jelenlétében, valamint:

a) Ugyanazon a frekvencián és 15 dB-el gyengébb; vagy

b) A frekvenciától plusz, vagy mínusz 2 kHz-el eltérő frekvencián és 4 dB-el gyengébb; vagy

c) Plusz, vagy mínusz 6 kHz-el, vagy ennél nagyobb mértékben eltérő frekvencián és 55 dB-el erősebb zavaró jel esetén sem.

Megjegyzés. – A fenti irányszögbeli hiba a légijármű mágneses iránytűjének hibáját nem számítva értendő.

3.10 (Fenntartva)

3.11 A mikrohullámú leszállító rendszer (MLS) jellemzői

3.11.1 Meghatározások

Auxiliary data. Kiegészítő adatok
Az alap adatokon kívül sugárzott olyan adatok, amelyek a fedélzeti helyzet számítások pontosításához a földi berendezés telepítési helyére vonatkozó információkat és más kiegészítő információkat biztosítanak.

Basic data. Alap adatok
A földi telepítésű berendezés által sugárzott azon adatok, amelyek a leszállító rendszer üzemelésével közvetlenül kapcsolatosak.

Beam centre. Sugárnyaláb középpont
A letapogató sugárnyaláb fő szirmának felfutó és lefutó élén lévő két mínusz 3 dB-es pont közötti felezőpont.

Beamwidth. Sugárszélesség
A letapogató sugárnyaláb fő szirmának szélessége, az, amit a mínusz 3 dB-es pontoknál mérnek, és szögegységekben állapítják meg, az antenna irányítási vonalnál a vízszintes síkban az oldalszög funkcióra, a függőleges síkban a magassági szög funkcióra.

Clearance guidance sector. Kiegészítő biztonsági-vezetési szektor
A légtérnek a fedésterületen belüli azon része, amelyen belül a biztosított oldalszög útirány-vezetési tájékoztatás nem arányos a légijármű szögeltérésével, de állandó balra, vagy jobbra kijelzés áll rendelkezésére arról, hogy a légijármű az arányos útirány-vezetési szektorhoz viszonyítva melyik oldalon van.

Control motion noise (CMN). Kormányzási elmozdulási zaj
Az útirány-vezetési jel hibájának az a része, amelyet a kormány felületek, a futók és az antennaoszlop elmozdulása okoz, és amelyet a légijárműnek az útirányra ráállt repülés közbeni térbeli helyzeti szöge befolyásolhat, de az, ami nem idézi elő a légijárműnek a megkívánt iránysávtól és/vagy siklópályától való eltérését. (Lásd a korábbi 3.5 pontot.)

Coordinate system - conical. Koordináta rendszer - kúpos
Egy funkcióra akkor mondjuk, hogy kúpos koordináta rendszert használ, amikor a dekódolt útirány-vezetési szög úgy változik, mint a vevő antennát magába foglaló kúp felülete és egy, a kúp tengelyére merőleges, annak csúcspontján áthaladó sík közötti minimális szög. A kúp csúcsa az antenna fázis-

középpontja. A megközelítési oldalszög, vagy hátsó irányszektor funkcióknál a sík az a függőleges sík, amely a futópálya középvonalát foglalja magába. A magassági szög funkciónál a sík vízszintes.

Coordinate system - planar. Koordináta rendszer - síkbeli
Egy funkcióra akkor mondjuk, hogy síkbeli koordinátákat használ, amikor a dekódolt útirány-vezetési szög egy, a vevő antennát magába foglaló sík és egy referencia sík közötti szögben változik. Az oldalszög funkciókra a referencia sík a futópálya középvonalát magába foglaló sík és az a sík, ami a vevő antennát magába foglalja, és egy függőleges síkként az antenna fázis-középpontján halad át.

Coverage sector. Fedésterületi szektor
A légtér egy olyan része, amelyen belül egy meghatározott funkciójú szolgáltatás kerül biztosításra, és amelyen belül a jel teljesítmény-sűrűsége a meghatározott minimummal egyenlő, vagy annál nagyobb.

DME/P. DME/P
Az MLS berendezés távolságmérő berendezése, ahol a "P" a pontos távolságmérést jelenti. A berendezés spektrum jellemzői olyanok, mint a DME/N berendezésé.

Function. Funkció
Az MLS berendezés által biztosított speciális szolgáltatás, azaz a megközelítési oldalszög útirány-vezetés, a hátsó irányszektor útirány-vezetés, vagy az alapadat stb.

Mean course error. Közepes irányszög hiba
Az oldalszög hiba közepes értéke, a futópálya meghosszabbított középvonala mentén.

Mean glide path error. Közepes siklópálya hiba
A magassági szög hiba közepes értéke, a magassági szög-vezetési funkció által biztosított siklópálya mentén.

Minimum glide path. Minimum siklópálya
A süllyedés legalacsonyabb szögértéke az a nulla fokos magassági szögön való süllyedés, amely megegyezik a megközelítési eljárásokban közzétett értékkel és az akadálymentességi követelményekkel.

Megjegyzés. - Ez az a legalacsonyabb süllyedési szög, amelyet a műszeres futópályára engedélyeztek és közzétettek.

MLS antenna boresight. Az MLS antenna irányítási (közép) vonala
Az a sík, ami az antenna fázis-középpontján az antenna rendszert magába foglaló vízszintes tengelyekre merőlegesen áthalad.

Megjegyzés. - Az oldalszög esetében az antenna irányítási (közép) vonal és a nulla fokos oldalszög általában egy egyenesbe esik. A műszaki összefüggésben előnyben részesített meghatározás az "antenna-irányítási (közép) vonal", míg az üzemeltetési összefüggésben az előnyben részesített meghatározás a "nulla fokos oldalszög" (lásd az alábbi meghatározást).

MLS azimuth. MLS oldalszög
A vízszintes síkokban azoknak a pontoknak a helyzete, ahol a dekódolt útirány-vezetési szög állandó.

MLS approach reference datum. MLS megközelítési vonatkozási pont
Egy meghatározott magasságú pont a futópálya középvonalának és küszöbének kereszteződése fölött.

MLS back azimuth reference datum. MLS hátirány irányszög vonatkozási pont
A futópálya középvonala fölött a futópálya közepénél meghatározott magasságban lévő pont.

MLS datum point. MLS alappont
A futópálya középvonalán a megközelítési magassági szög antenna fázis-középpontjához legközelebb lévő pont.

MLS elevation. MLS magassági szög
Azoknak a pontoknak a helyzete a függőleges síkokban, ahol a dekódolt útirány-vezetési szög állandó.

MLS zero degree azimuth. MLS nulla fokos oldalszög
Az az MLS oldalszög, ahol a dekódolt útirány-vezetési szög nulla fokos.

Out-of-coverage indication signal. Fedésterületen-kívül kijelzés
A tervezett fedésterületi szektoron kívüli területre kisugárzott jel ott, ahol kifejezetten szükséges a fedélzeti riasztás jelzésből az érvénytelen jel eltávolításának megelőzése a félrevezető útirány-vezetési információk jelenléte esetén.

Path following error (PFE). Útvonal követési hiba
Az útirány-vezetési jel hibájának az a része, amely előidézheti azt, hogy a légijármű a megkívánt útiránytól és/vagy siklópályától eltérjen.

Path following noise (PFN). Útvonal követési zaj
Az útirány-vezetési jel hibájának az a része, amely előidézheti azt, hogy a légijármű a megkívánt közepes iránysáv vonaltól és közepes siklópályától eltérjen, amelyik a megfelelő.

Proportional guidance sector. Arányos útirány-vezetési szektor
A légtérnek a fedésterületen belüli azon része, melyen belül a funkciónak megfelelően biztosított oldalszög útirány-vezetési tájékoztatás egyenesen arányos a légijármű fedélzeti antennának a nulla fokos referenciától való szögeltérésével.

3.11.2 Általános rész

3.11.2.1 Az MLS egy olyan precíziós megközelítési és leszállító útirány-vezetést adó rendszer, amely helyzet-információkat és különféle föld-levegő adatokat biztosít. A helyzetre vonatkozó információkat széles fedési szektoron belül biztosítja, és az oldalszög mérésével, a magassági szög mérésével és a távolság mérésével határozza meg.

Megjegyzés. - Hacsak nincs külön jelezve az, hogy MLS légijármű fedélzeti berendezésről van szó, akkor a 3.11 szakasz szövege az MLS földi berendezésre vonatkozik.

3.11.3 MLS konfigurációk

3.11.3.1 *Alap MLS.* Az MLS alap konfigurációjának a következőket kell tartalmaznia:

a) megközelítési oldalszög berendezést, a hozzá kapcsolódó felügyelő rendszert, távirányító és kijelző berendezést;

b) megközelítési magassági szög berendezést, a hozzá kapcsolódó felügyelő rendszert, távirányító és kijelző berendezést;

c) a fontos adat szavak kódolásának és adásának eszközét, a hozzá kapcsolódó felügyelő rendszert, távirányító és kijelző berendezést;

Megjegyzés. - A fontos adatok csak azok az alapadatok és kiegészítő adatok, amelyeket a 3.11.5.4 pont meghatároz.

d) DME/N-t, a hozzá kapcsolódó felügyelő rendszert, távirányító és kijelző berendezést.

3.11.3.2 **Ajánlás**. - *Ha pontos távolság információ szükséges az oldalszög fedéserületi szektoron belül, akkor választható lehetőségként a 3. Fejezet 3.5 pontjában meghatározott szabványoknak megfelelő DME/P berendezést kell alkalmazni.*

Megjegyzés. - A DME az MLS távolság-adó berendezése, és így az az elvárás, hogy amint lehetséges, telepítésre kerüljön. Azonban az ILS-hez telepített hely-jeladó berendezéseket is fel lehet használni ideiglenesen az MLS-el együtt addig, amíg az ILS szolgáltatást ugyanazon futópályához fenntartják.

3.11.3.3 *Kibővített MLS kialakítás*. Megengedhető kell, hogy legyen az, hogy az alap MLS-ből kibővített kialakítású rendszert építsenek ki a következő funkciók, vagy tökéletesítő jellemzők közül egy, vagy több hozzáadásával:

a) hátsó irányszektor adó berendezés, a hozzá kapcsolódó felügyelő rendszerrel, távirányító és kijelző berendezéssel;

b) kilebegtetési magasság adó berendezés, a hozzá kapcsolódó felügyelő rendszerrel, távirányító és kijelző berendezéssel;

c) DME/P, a hozzá kapcsolódó felügyelő rendszerrel, távirányító és kijelző berendezéssel;

d) további kiegészítő adatszavak kódolásának és adásának eszköze, a hozzá kapcsolódó felügyelő rendszerrel, távirányító és kijelző berendezéssel;

e) egy szélesebb arányos vezetési szektor, amely meghaladja a következőkben a 3.5.11 pontban meghatározott minimumot.

1. Megjegyzés. - Jóllehet, a szabvány úgy került kidolgozásra, hogy biztosítja a kilebegtetési magasság megadásának funkcióját, mégis, ezt a funkciót nem teljesíti és a jövőbeli teljesítés sincs figyelembe véve.

2. Megjegyzés. - Az MLS jelformátum lehetőséget biztosít a rendszer további bővítésére, olyan funkciók bevezetésére, mint például a 360 fokos irányszög.

3.11.3.4 *Egyszerűsített mikrohullámú leszállító rendszer (MLS) konfigurációk*. Megengedhetőnek kell lenni annak, hogy egyszerűsített konfigurációt nyerjenek az alap mikrohullámú rendszerből (MLS) (3.11.3.1) a következő jellemzők enyhítésével:

a) a megközelítési oldalszög fedésterület csak a megközelítési területen (3.11.5.2.2.1.1) biztosított;

b) a megközelítési oldalszög és magassági szög fedésterület (3.11.5.2.2 és 3.11.5.3.2) nem kerül kiterjesztésre a küszöb feletti 30 méteres (100 láb) magasság alá;

c) az útvonal-követési hiba (PFE) és az útvonal-követési zaj (PFN) pontossági határértékei megnövelésre kerülnek úgy, hogy azok a 3.11.4.9.4 pontban a megközelítési oldalszög útirány-vezetésre meghatározott értékek és a 3.11.4.9.6 pontban a magassági szög útirányvezetésre meghatározott értékek 1,5-szeresénél nem nagyobbak legyenek;

d) a földi berendezésnek a közepes irányszög hibához és a közepes siklópálya hibához való hozzájárulása megnövelésre kerülnek úgy, hogy azok a 3.11.5.2.4 pontban és a 3.1.5.3.4 pontban meghatározott értékek 1,5-szeresei legyenek;

e) a kormányzási elmozdulási zaj (CMN) követelményeiről (3.11.4.9.4 és 3.11.4.9.6) lemondanak; és

f) a felügyelő és az irányító tevékenység időtartama (3.11.5.2.3 és 3.11.5.3.3) hat - másodperces időtartamra kerül megnövelésre.

Megjegyzés. - Az egyszerűsített mikrohullámú leszállító rendszer (MLS) konfiguráció alkalmazására vonatkozó útmutató anyagot a "G"- Melléklet 15. pontja adja meg.

3.11.4 A térbeli jel jellemzői - szög és adat funkciók

3.11.4.1 *Csatorna kiválasztás*

3.11.4.1.1 *Csatorna elrendezés*. Az MLS szög és adat funkcióinak az 5 031,0 MHz-től az 5 090,7 MHz-ig terjedő - az A-táblázatban megadott - frekvenciákban kijelölt 200 csatorna valamelyikén kell működni.

3.11.4.1.1.1 A csatorna kijelölést a 3.11.4.1.1 pontban meghatározottak kiegészítéseként az 5 030,4-től az 5 150,0 MHz-ig terjedő 'segédsávból' kell kiválasztani, ahogy az a jövő léginavigációs követelményei szerint szükséges.

3.11.4.1.2 *Csatorna párosítás a DME-vel*. Az irányszög és adat csatornáknak a távolság funkciót ellátó csatornával való párosítását az A-táblázatban leírtaknak megfelelően kell meghatározni.

3.11.4.1.3 *Frekvencia tűréshatár*. A földi telepítésű berendezés üzemi rádiófrekvenciája nem térhet el plusz, vagy mínusz 10 kHz-nél nagyobb mértékben a kijelölt frekvenciától. A frekvencia tartásnak olyannak kell lennie, hogy a névleges frekvenciától való eltérés a plusz, vagy mínusz 50 Hz-es értéken belül legyen, amikor azt 1 másodperces időtartamon keresztül mérik.

3.11.4.1.4 *A rádiófrekvenciás jel spektruma*.

3.11.4.1.4.1 A kisugárzott jelnek olyannak kell lenni, hogy az adás ideje alatt a közepes teljesítmény-sűrűség 600 méter (2 000 láb) magasság fölött ne lépje túl a mínusz 94,5 dBW/m^2 értéket az irányszög útirány-vezetésre, a névleges frekvenciától 840 kHz-re, vagy annál nagyobb középpontú 150 kHz-es sávszélességben.

3.11.4.1.4.2 A kisugárzott jelnek olyannak kell lenni, hogy az adás ideje alatt a közepes teljesítmény-sűrűség bármelyik antennától mérve 4 800m-en (2,6 tengeri mérföldön) túl és 600m-es (2 000 láb) magasság alatt ne lépje túl a mínusz 94,5 dBW/m^2 értéket az irányszög útirány-vezetésre, a névleges frekvenciától 840 kHz-re, vagy annál nagyobb középpontú 150 kHz-es sávszélességben.

1. Megjegyzés. – A 3.11.4.1.4.2 pont alatti követelmények akkor alkalmazhatók, ha egy másik MLS földi állomás üzemelési lefedési területe és a tekintetbe vett földi állomás rádió-horizontja között átfedés van.

2. Megjegyzés. – Az MLS frekvencia tervezésre vonatkozó útmutató anyag a "G"- Melléklet 9.3. pontjában került megadásra.

3.11.4.2 *Polarizáció*. Valamennyi földi telepítésű berendezéstől származó adás rádiófrekvenciájának névlegesen függőlegesen polarizáltnak kell lennie. Semmilyen polarizált összetevőnek nem lehet olyan hatása, hogy az útirány-vezetési tájékoztatásokat - az arra a helyre megengedett és a függőleges helyzettől 30 fokkal elfordított légijármű fedélzeti antennánál - az útvonal-követési hiba (PFE) 40 százaléknál nagyobb értékkel megváltoztassa, vagy létrehozza azt, hogy az útvonal-követési hiba határértékét túllépje.

3.11.4.3 Az *időosztásos multiplex (TDM) szervezése*

3.11.4.3.1 Mindkét, mind a szög információt, mind az adatot időosztásos multiplex-el kell sugározni egyetlen rádiófrekvencia csatornán.

3.11.4.3.2 *Szinkronizálás*. Azokat a földi telepítésű, irányszög és adat sugárzó berendezéstől származó adásokat, amelyek egy adott futópályát szolgálnak ki, időben kell szinkronizálni úgy, hogy az interferenciamentes működés biztosítva legyen az üzemelés közös rádiófrekvencia csatornáján.

3.11.4.3.3 *Funkció sebességek*. Az egyes kisugárzott funkciókat a következő táblázatban megadott ütemben kell kisugározni:

Funkció	Bármely 10 másodperces időtartam alatt mért átlag ütem (Hz)
Megközelítési oldalszög útirány-vezetés	13 ± 0,5
Nagysebességű megközelítési oldalszög útirány-vezetés	39 ± 1,5
Hátsó irányszektor útirány-vezetés	6,5 ± 0,25
Megközelítési magassági útirány-vezetés	39 ± 1,5
Kilebegtetési magassági útirány-vezetés	39 ± 1,5
Alap adatok	Lásd az 'A' - Függelék A-7. Táblázatát
Kiegészítő adatok	Lásd az 'A' - Függelék A-10. és A-12. Táblázatát

3.11.4.3.3.1 **Ajánlás**. - *Amikor az arányos útirány-vezetési szektor nem nagyobb plusz, vagy mínusz 40 foknál és a kilebegtetési magasság, vagy más bővített funkció nem szükséges, akkor a nagysebességű megközelítési oldalszög útirány-vezetés funkciót kell használni.*

Megjegyzés. - Az alkalmazásra vonatkozó tájékoztatás a "G"- Melléklet 2.3.3 pontjában található.

3.11.4.3.4 *Funkció időzítés*. Az egyes szög- és adat funkcióra az időzítési szabványok azok, amelyeket az A- Függelék A-1.-től A-6.-ig terjedő táblázataiban és az A-8. táblázatában meghatározásra kerültek. A földi berendezés valamennyi felsorolt funkciójának belső időzítési pontossága - a vibrálást (jitter) is beleértve – plusz, vagy mínusz 2 mikroszekundum eltéréssel a meghatározott névleges értéknek kell lenni. Az időzítési vibrálásnak 1 mikroszekundum négyzetes középértéknél (RMS) kisebbnek kell lennie.

1. Megjegyzés. - Valamennyi felsorolt funkció időzítése jelzi az adott esemény idő-rés kezdetét és az előző esemény idő-rés végét. Az aktuális adás karakterisztikája és időzítése meg kell, hogy feleljen az alkalmazandó pontokban előírtaknak.

2. Megjegyzés. - Az időzítési pontosság mérésére vonatkozó tájékoztatás a "G"- Melléklet 2.2.2 pontjában található.

3.11.4.3.5 *Funkció sorrend*. Bármely funkció adásismétlődése közötti időtartam úgy kell, hogy változzon, ami a szinkron-interferencia elleni védettséget biztosítja.

1. Megjegyzés. - Valamennyi funkció sajátos jellemzőkkel rendelkezik és az időosztásos multiplex (TDM) sorrend bármely helyén szerepelhet (a hátsó irányszektor kivételével, amelyet mindig meg kell, hogy előzzön a 2. számú alapadat szó).

2. Megjegyzés. - Néhány olyan sorrend, amely szinkron interferencia-mentesnek bizonyult, a "G"-Melléklet 2.1.4 pontjában kerül ismertetésre.

3.11.4.4 *Bevezető jelszakasz*

3.11.4.4.1 Egy bevezető jelszakasz (előtag) jelet kell sugározni a felhasználható fedési szektor egész területére, az utána következő funkció azonosítása céljából. A bevezető jelszakasznak tartalmaznia kell egy rádiófrekvenciás vivőhullám begyűjtési periódust, egy vevő referencia idő kódot és egy funkció azonosító kódot. A bevezető jelszakasz adás időzítésének az A - Függelék A-1. táblázatában meghatározottaknak kell lenni.

3.11.4.4.2 *Vivőhullám begyűjtés*. A bevezető jelszakasz adását egy modulálatlan rádiófrekvenciás vivőhullámmal kell kezdeni, úgy, ahogy az az 'A'-Függelék A-1. táblázatában meghatározásra került.

3.11.4.4.3 *Moduláció és kódolás*

3.11.4.4.3.1 *Differenciális fázis eltolásos kódolás (DPSK).* Az alábbi 3.11.4.8 pontban meghatározott bevezető jelszakasz kódokat, valamint az alap és kiegészítő adatok jeleit a rádiófrekvenciás vivőhullám differenciális fázis eltolásos kódolásával (DPSK) kell leadni. A "nullát" a 0 fokos, plusz, vagy mínusz 10 fokos fáziseltolás, az "egyet" pedig a 180 fokos, plusz, vagy mínusz 10 fokos fáziseltolás kell, hogy képviselje. A modulációs sebességnek 15 625 baud-nak (bit/mp) kell lenni. A differenciális fázis eltolásos kódolás fázisátmenete belső időzítési pontosságának a korábbi 3.11.4.3.4 pontban meghatározottnak kell lenni. A fázisátmenet során nem lehet amplitúdó-modulációt alkalmazni. Az átmeneti idő nem haladhatja meg a 10 mikroszekundumot, és a fázis-sietésnek valamint a fázis-késésnek egyformának kell lenni egy átmeneti szakaszban.

3.11.4.4.3.2 *A vevő vonatkoztatási ideje*. Minden egyes bevezető jelszakasznak magába kell foglalnia egy vevő azonosítási idő kódot, a 11101-et (az I_1 - I_5 bitek). A kódban lévő utolsó fázisátmenet középpontja idejének kell a vevő vonatkoztatási időnek lenni. A vevő vonatkoztatási idő kódot, a vevő vonatkoztatási idő kódot közvetlenül követő érvényes funkció azonosítás dekódolásának kell érvényesíteni.

3.11.4.4.3.3 *Funkció azonosítás*. A vevő vonatkoztatási idő kód után egy funkció azonosító kódnak kell következni. Ennek a kódnak abból az öt információs bitből kell állnia (I_6 - I_{10}), amelyek lehetővé teszik a 31 különböző funkció azonosítását, és még két ellenőrző bitből (I_{11} és I_{12}) úgy, ahogy azt a következő táblázat mutatja:

	Kódok						
Funkció	I_6	I_7	I_8	I_9	I_{10}	I_{11}	I_{12}
Megközelítési oldalszög	0	0	1	1	0	0	1
Nagysebességű megközelítési oldalszög	0	0	1	0	1	0	0
Megközelítési magassági szög	1	1	0	0	0	0	1
Kilebegtetési magasság	0	1	1	0	0	0	1
Hátsó irányszektor	1	0	0	1	0	0	1
360°-os oldalszög	0	1	0	0	1	0	1
Alapadat 1	0	1	0	1	0	0	0
Alapadat 2	0	1	1	1	1	0	0
Alapadat 3	1	0	1	0	0	0	0
Alapadat 4	1	0	0	0	1	0	0
Alapadat 5	1	1	0	1	1	0	0
Alapadat 6	0	0	0	1	1	0	1
Kiegészítő adat A	1	1	1	0	0	1	0
Kiegészítő adat B	1	0	1	0	1	1	1
Kiegészítő adat C	1	1	1	1	0	0	0

Megjegyzés. - A funkció azonosító kódokat úgy kell kiválasztani, hogy az I_{11} és I_{12} paritás bitek kielégítsék az egyenleteket:

$$I_6 + I_7 + I_8 + I_9 + I_{10} + I_{11} = \text{PÁROS}$$

$$I_6 + I_8 + I_{10} + I_{12} = \text{PÁROS}$$

3.11.4.5 *Szög útirány-vezetési paraméterek.* A szög útirány-vezetési információkat a vett TO és FRO letapogató sugárnyalábok fő szirmainak középpontjai közötti idő-elkülönítés mennyiségével kell kódolni. A kódolást a fedélzeti berendezésnek kell kiértékelni az idő lineáris függvényeként a következők szerint:

$$\theta = (T_0 - t)\ V/2$$

ahol:

θ = Az oldalszög, vagy a magassági szög útirány-vezetési szögének értéke, fokokban,

t = A TO és az FRO sugárnyaláb középpontja közötti idő-elkülönítés, mikroszekundumban,

T_0 = A nulla fokoknak megfelelő TO és FRO sugárnyaláb középpontja közötti idő-elkülönítés, mikroszekundumban,

V = A letapogatási sebesség leosztási állandója mikroszekundumonként, fokokban.,

3.11.4.5.1 A szög útirány-vezetési paraméterek értékeinek a következő táblázatban bemutatottaknak kell lenni:

Funkció	Maximális letapogatási szög (fok)	A t értéke a maximális letapogatási szöghöz (μs)	T0 (μ)	V (fok/μs)
Megközelítési oldalszög	-62-től +62-ig	13 000	6 800	0,020
Nagysebességű megközelítési oldalszög	-42-től +42-ig	9 000	4 800	0,020
Hátsó irányszektor	-42-től +42-ig	9 000	4 800	-0,020
Megközelítési magassági szög	-1,5-től +29,5-ig	3 500	3 350	0,020
Kilebegtetési magasság	2-től +10-ig	3 200	2 800	0,010

1. Megjegyzés. - A TO letapogatás vége és az FRO letapogatás kezdete között van egy megfelelő időtartamú sugárzás nélküli szünet idő. A kiegészítő tájékoztatásokat a "G"- Melléklet 2.2.1 pontja adja meg.

2. Megjegyzés. - A bemutatott maximális letapogatási szögeknél elfogadott az, hogy a letapogatási szögnek - a sikeres dekódolás lehetővé tételéhez - legalább a detektált letapogatási sugárnyaláb burkológörbéje szélességének a felével meg kell haladnia (a megfelelő értékű szögben) az arányos útirány-vezetési szektor határait.

3.11.4.5.2 A földi berendezés letapogató sugárnyaláb sebessége tűréshatárának és a nulla fokoknak megfelelő TO és FRO impulzusok közötti idő-elkülönítés tűréshatárának kielégítőnek kell lenni ahhoz, hogy a következő 3.11.4.9 pontban meghatározott pontossági követelményeket kielégítse.

3.11.4.5.3 A TO és FRO letapogatási adásokat szimmetrikusan kell beszabályozni az A- Függelék A-2-től A-5-ig tartó táblázataiban felsorolt letapogatási középpontok köré. A letapogatási középpontoknak és a TO, valamint FRO letapogatási adások közötti időköz közepének egybe kell esni a plusz, vagy mínusz 10 mikroszekundumos tűréshatárral.

3.11.4.6 *Oldalszög útirány-vezetés funkciók*

3.11.4.6.1 Az útirány-vezetési szög minden egyes leadásának magába kell foglalnia egy, az óramutató járásával megegyező irányú TO letapogatást és azt követően egy, az óramutató járásával ellentétes irányú FRO letapogatást az antenna felettről nézve. A megközelítési oldalszög funkcióra a növekvő szögértékeknek kell a TO letapogatás irányába lenni. A hátsó irányszektor funkciónál a növekvő szögértékeknek kell az FRO letapogatás irányába lenni.

Megjegyzés. - A letapogatási szabályokat bemutató ábrát a "G"- Melléklet 2.3.1 pontja tartalmazza.

3.11.4.6.2 *Szektor jelek*. Minden oldalszög funkció leadási formátumának magába kell foglalnia a légijármű fedélzeti antenna kiválasztási idő-rést, a fedésterületen kívül jelzést és a vizsgáló impulzusokat, úgy, ahogy ez az ”A”- Függelék A-2 és A-3 táblázataiban meghatározásra került. A szektorjelek belső időzítési pontossága meg kell, hogy feleljen a korábbi 3.11.4.3.4 pontban a differenciális fázis-eltolásos kódolás (DPSK) leadására meghatározott belső időzítési pontosságnak.

3.11.4.6.2.1 *A földi berendezés azonosítása*. Egy adott futópályát kiszolgáló MLS berendezést egy négy-betűs, M-betűvel kezdődő betűcsoport azonosítóval kell azonosítani. Ezt az azonosító jelzést kell az első betű nélkül egy digitális szóként leadni az ”A”- Függelék A-7. táblázatában felsoroltak szerint.

Megjegyzés. - Nem szükséges az, hogy az MLS földi berendezés a szög útirány-vezetési fedésterületi szektoron kívülre azonosítót adjon le. Ha az MLS csatorna azonosítás a szög útirány-vezetési fedésterületi szektoron kívülre üzemeltetési szempontból szükséges, akkor azt biztosítani lehet egy kapcsolt telepítésű körkörös sugárzású DME-től. (Lásd az alábbi 3.11.5.5.2 pontot és a “G”- Melléklet 8.2 pontját.)

3.11.4.6.2.1.1 A jelzést az adat csatornán a megközelítési oldalszög és a hátsó irányszektor fedésterületre kell leadni.

3.11.4.6.2.1.2 Az oldalszög bevezető jelszakaszt követő - a földi berendezés azonosítására szolgáló - előzetesen kiosztott váltakozó (Morse-kód), az idő-résben lévő kód bitet a "NULLA" helyzetben kell rögzíteni.

3.11.4.6.2.2 *Légijármű fedélzeti antenna kiválasztó jel.* A légijármű fedélzeti antenna kiválasztó jelet egy "nulla" - hat-bit időtartam hosszúságú - differenciális fázis-eltolásos kódolású (DPSK) jelként kell kisugározni. A jelnek rendelkezésre kell állni azon teljes fedési szektoron belül, amelyben a megközelítési, vagy a hátsó irányszektor útirány-vezetés biztosítva van.

Megjegyzés. - Ez a jel biztosítja a legmegfelelőbb antenna kiválasztási lehetőséget egy több-antennás fedélzeti felszerelés esetén.

3.11.4.6.2.3 *Oldalszög fedésterületen-kívül jelző impulzus*. Ahol fedésterületen-kívül jelző impulzusokat használnak, ott azoknak:

a) nagyobbaknak kell lenni bármilyen, a fedésterületen kívüli szektorban lévő útirány-vezetési jelnél;

b) legalább 5 dB-el kisebbnek kell lenni a tartson-balra (tartson-jobbra) terület jelszintjénél a tartson-balra (tartson-jobbra) biztonsági területen belül, és

c) legalább 5 dB-el kisebbnek kell lenni az arányos fedési területen belüli letapogató sugárnyaláb szintjénél.

Az egyes impulzusok fél amplitúdó pontban mért időtartamának legkevesebb 100 mikroszekundumnak, a felfutási és lefutási időnek pedig 10 mikroszekundumnál kisebbnek kell lenni.

3.11.4.6.2.3.1 Ha kívánatos, akkor megengedhetőnek kell lenni két egymás utáni impulzus kisugárzásának az egyes fedésterületen-kívül jelzés idő-réseiben. Ahol ilyen impulzus-párokat alkalmaznak, ott az egyes impulzusok időtartamának legalább 50 mikroszekundumnak kell lenni, és a felfutási és lefutási időnek 10 mikroszekundumnál kisebbnek kell lenni.

3.11.4.6.2.3.2 Az egymás fedési diagramját átfedő antennákból kisugárzott fedésterületen-kívül jelző impulzusokat legalább 10 mikro-szekundummal el kell különíteni egymástól.

3.11.4.6.2.4 *Földről kisugárzott vizsgáló jelzések*

Megjegyzés. - Az oldalszög útirány-vezetési jel formátumban egy időtartam került fenntartásra a földről kisugárzott vizsgáló jelzések jövőbeli felhasználásának lehetővé tételéhez.

3.11.4.6.2.5 Kiegészítő biztonsági-vezetési szektor. Ahol a biztosított arányos útirány-vezetési szektor kisebb annál a minimális fedésterületnél, mint ami az alábbi 3.11.5.2.2.1.1 a) és 3.11.5.2.2.2 a) pontban meghatározásra kerül, ott kiegészítő biztonsági vezetést kell biztosítani a fedésterületi szektornak a tartson-balra / tartson-jobbra biztonsági impulzusok kisugárzásával való kiegészítésénél a megközelítési oldalszög, a nagysebességű megközelítési oldalszög és a hátsó irányszektor funkciók formátumában. Másik lehetőségként megengedhetőnek kell lennie annak, hogy a kiegészítő biztonsági vezetés úgy legyen biztosítva, ami lehetővé teszi azt, hogy a letapogató sugárnyaláb a kijelölt arányos útirány-vezetési szektoron kívülre is kiterjen, és megadja a tartson-balra, vagy tartson-jobbra biztonsági tájékoztatásokat, ahogy megfelelő, akkor, amikor a dekódolt szög meghaladja az arányos útirány-vezetési fedés kijelölt határait.

3.11.4.6.2.5.1 A kiegészítő biztonsági-vezetési információkat a szög letapogatási idő-réseken belül leadott impulzus-párokkal kell biztosítani. Az első impulzus-párnak magába kell foglalnia egy olyan impulzust, ami a letapogató sugárnyaláb TO letapogatásának az indulási idejével szomszédos, és egy olyan impulzust, ami a FRO letapogatás megállási idejével szomszédos. A második impulzus-párnak magába kell foglalnia egy olyan impulzust, ami a letapogató sugárnyaláb TO letapogatásának megállási idejével szomszédos, és egy olyan impulzust, ami a FRO letapogatás indulási idejével szomszédos. A tartson-jobbra biztonsági impulzusoknak pozitív szöget kell képviselni, a tartson-balra biztonsági impulzusoknak pedig negatív szöget kell képviselni. Az egyes biztonsági impulzusok impulzus-szélességének – plusz, vagy mínusz 5 mikroszekundum tűrés-határral - 50 mikroszekundumnak kell lenni. Az adó kapcsolási ideje a biztonsági impulzusok és a letapogató sugárnyaláb adása között nem haladhatja meg a 10 mikroszekundumot. Az impulzus felfutási idő az egyes biztonsági impulzusok azon éleinél, amelyek nem szomszédosak a letapogató sugárnyalábbal, 10 mikroszekundumnál kevesebb kell, hogy legyen.

3.11.4.6.2.5.2 A kiegészítő biztonsági-vezetési impulzusok térbeli jel karakterisztikáinak a következőknek kell lenni:

a) a tartson-jobbra kiegészítő biztonsági-vezetési szektorban a tartson-jobbra biztonsági-vezetési jelnek legalább 5 dB-el meg kell haladni a letapogató sugárnyaláb oldalszirmait és az összes egyéb útirány-vezetési és fedésterületen-kívül jelzés jeleit;

b) a tartson-balra kiegészítő biztonsági-vezetési szektorban a tartson-balra biztonsági-vezetési jelnek legalább 5 dB-el meg kell haladni a letapogató sugárnyaláb oldalszirmait és az összes egyéb útirány-vezetési és fedésterületen-kívül jelzés jeleit;

c) az arányos útirány-vezetési szektoron belül a biztonsági-vezetési jeleknek legalább 5 dB-el alatta kell lenni a letapogató sugárnyaláb fő szirma alatt.

3.11.4.6.2.5.3 A biztonsági-vezetési jelek teljesítménysűrűségének meg kell felelni annak, ami az alábbi 3.11.4.10.1 pont szerint szükséges.

1. Megjegyzés. - A "G"- Melléklet 2.3.4 pontja a következőkre vonatkozó tájékoztatásokat foglalja magába:

a) a biztonsági-vezetési és a letapogató sugárnyaláb időzítési rendszerét;

b) a biztonsági-vezetési és a letapogató sugárnyaláb jelei közötti átmeneti tartományban lévő impulzusok burkológörbéit;

c) a biztonsági-vezetési jelek (tartson-jobbra / tartson-balra) szabályainak változásait.

2. Megjegyzés. - Az arányos fedésterület határvonalai az alap adatokban kerülnek adásra úgy, ahogy ez az alábbi 3.11.4.8.2 pontban meghatározásra kerül.

3.11.4.7 *Magassági szög útirány-vezetési funkciók*

3.11.4.7.1 *Letapogatási szabályok*. A megközelítési magassági szög funkciónál a növekvő magassági szög útirány-vezetési szögeknek felfelé kell növekedniük. A nulla magassági szögnek egybe kell esni azzal a vízszintes síkkal, amely a megfelelő antenna fázis-középpontján áthalad. Minden egyes magassági szög leadásnak tartalmazni kell egy TO letapogatást, amelyet egy FRO letapogatás követ. A TO letapogatásnak kell a növekvő szög értékek irányában lenni.

3.11.4.7.2 *Szektor jel*. Egy fedésterületen-kívül jelző impulzus sugárzására helyet kell biztosítani a megközelítési magassági szög funkció formátumában. Ahol egy fedésterületen-kívül jelző impulzust alkalmaznak, ott annak: (1) nagyobbnak kell lenni bármilyen, a fedésterületen-kívül jelzés szektorban lévő útirány-vezetési jelnél és (2) legalább 5 dB-el kisebbnek kell lenni az útirány-vezetési szektorban lévő útirány-vezetési jeleknél. A magassági szög fedésterületen-kívül jelzés időzítésének az "A"- Függelék A-4. táblázatában megadottakkal megegyezőnek kell lenni. Az egyes impulzusok impulzusszélességének a fél amplitúdó pontokban mérve legalább 100 mikroszekundumnak és a felfutási és lefutási időknek 10 mikroszekundumnál kevesebbnek kell lenniük.

3.11.4.7.2.1 Ha kívánatos, akkor megengedhetőnek kell lenni két egymás utáni impulzus kisugárzásának az egyes akadálymentesség jelzés időréseiben. Ahol ilyen impulzus-párokat alkalmaznak, ott az egyes impulzusok időtartamának legalább 50 mikroszekundumnak, és a felfutási és lefutási időnek 10 mikroszekundumnál kisebbnek kell lenni.

3.11.4.8 *Adat funkciók*. Az MLS jel formátumban biztosítani kell az alap adatok és a kiegészítő adatok sugárzását.

Megjegyzés. - A földi berendezések adat továbbítására és felügyelő rendszerére vonatkozó követelmények a következő 3.11.5.4 pontban kerülnek meghatározásra.

3.11.4.8.1 *Adatok sugárzása*. Az adatokat a 3.11.4.4.3.1 pontban meghatározottak szerint kell sugározni.

3.11.4.8.2 *Az Alap adatok szerkezete és időzítése*. Az alap adatokat 32-bites szavakba kell kódolni, és ezeket a korábbi 3.11.4.4 pontban meghatározott funkció bevezető jelszakaszból (12 bit) és az "A"- Függelék A-7. táblázatában meghatározott adott tartalomból kell összeállítani. Az alap adat szavak időzítése az "A"- Függelék A-6. táblázatában meghatározottaknak megfelelő kell, hogy legyen. A tartalom, az ugyanazon szavak leadása közötti maximális időköz és a szavak szervezése meg kell, hogy feleljen az "A"- Függelék A-7. táblázatában meghatározottaknak. A digitális adatokat tartalmazó információkat a legkisebb helyértékű bittel kezdve kell kisugározni. A legkisebb bináris szám jelenti az alsó abszolút tartomány határt, bináris lépésekkel növekedve az abszolút tartomány felső határáig, az ”A”- Függelék A-7. táblázatában előírtaknak megfelelően.

3.11.4.8.2.1 *Az Alap adatok tartalma*. Az ”A”- Függelék A-7. táblázatában meghatározott adat elemeket a következők szerint kell értelmezni:

a) *A Megközelítési oldalszög antenna és a futópálya küszöbe közötti távolság* azt a minimális távolságot jelenti, ami a megközelítési oldalszög antenna fázis középpontja és a futópálya küszöbét magába foglaló, a futópálya középvonalára merőleges függőleges sík között van.

b) *A Megközelítési oldalszög arányos fedésterület határvonal* annak a szektornak a határvonalait jelenti, amelybe az arányos megközelítési oldalszög útirány-vezetés sugárzásra kerül.

c) *A Kiegészítő biztonsági jel típusa* az oldalszög kiegészítő biztonsági jel biztosításának módját jelenti.

d) *A Minimális siklópálya* a nulla fokos oldalszög mentén a 3.11.1 pontban meghatározottaknak megfelelő legalacsonyabb süllyedési szöget jelenti.

e) *A Hátsó irányszektor állapota* a hátsó irányszektor berendezés működési állapotát jelenti.

f) *A DME állapota* a DME berendezés működési állapotát jelenti.

g) *A Megközelítési oldalszög állapot* a megközelítési oldalszög adó berendezés működési állapotát jelenti.

h) *A Megközelítési magassági szög állapota* a megközelítési magassági szög adó berendezés működési állapotát jelenti.

i) *A Sugárnyaláb szélesség* az adott funkció antennájának a sugárnyaláb szélességét jelenti úgy, ahogy azt a 3.11.1 pont meghatározza.

j) *A DME távolság* azt a minimális távolságot jelenti, ami a DME antenna fázis középpontja és az MLS alappontját magába foglaló és a futópálya középvonalára merőleges függőleges sík között van.

k) *A Megközelítési oldalszög mágneses tájolása* azt a szöget jelenti, amely a vízszintes síkban a Mágneses Északtól az óramutató járásával megegyező irányban, a megközelítési oldalszög-adó antennájától kiindulóan a nulla-fokos megközelítési oldalszögig mért szög. A mért szög csúcspontjának a megközelítési oldalszög adó antenna fázis középpontjának kell lenni.

l) *A Hátsó irányszektor mágneses tájolása* azt a szöget jelenti, amely a vízszintes síkban a Mágneses Északtól az óramutató járásával megegyező irányban, a hátsó irányszektor adó antennájától kiindulóan a hátsó irányszektor nulla-fokos irányszögig mért szög. A mért szög csúcspontjának a hátsó irányszektor adó antenna fázis középpontjának kell lenni.

m) *A Hátsó irányszektor arányos fedésterület határvonala* annak a szektornak a határvonalait jelenti, amelybe az arányos hátsó irányszektor útirány-vezetés sugárzásra kerül.

n) *Az MLS földi berendezés azonosítója* a 3.11.4.6.2.1 pontban előírtak szerinti rendszer azonosító utolsó három karakterét jelenti. A karaktereket az 5.sz. Nemzetközi Távíró ABC (IA-5) előírásai szerint kell kódolni a b_1-től a b_6-ig terjedő bitek felhasználásával.

1. Megjegyzés. - Az 5.sz. Nemzetközi Távíró ABC (IA-5) az Annex 10 III. Kötetében van meghatározva.

2. Megjegyzés. - Ennek a kódnak a b_7 bitjét a légijármű fedélzeti vevő a b_6 bit-el való kiegészítéssel állíthatja helyre.

3.11.4.8.3 *A Kiegészítő adatok szervezése és időzítése*. A Kiegészítő adatokat 76-bites szavakba kell szervezni, és ezeknek a 3.11.4.4 pont szerint meghatározott (12-bites) funkció bevezető jelszakaszból (előtagból), az ”A”- Függelék A-9. táblázatában meghatározottaknak megfelelő (8-bites) címből és az ”A”- Függelék A-10., A-11., A-12., A-13. és A-15. táblázatában meghatározottaknak megfelelő adat tartalomból és paritás bitekből (56 bit) kell állni. Három funkció azonosító kód lefoglalásra került a Kiegészítő adat ’A’, a Kiegészítő adat ’B’ és a Kiegészítő adat ’C’ adásának jelzésére. A Kiegészítő adat funkció időzítésének annak kell lenni, ami az ”A”- Függelék A-8. táblázatában előírásra került. Két Kiegészítő adat szó formátumot kell biztosítani, egyet a digitális adatokhoz és egyet az alfanumerikus karakter adatokhoz. A digitális információkat tartalmazó adatokat először a legkisebb helyértékű bit kisugárzásával kell leadni. Az ABC-karaktereket a B1-től a B39-ig terjedő adat szavakban, az 5.sz. Nemzetközi Távíró ABC (IA-5) előírásaival összhangban kell kódolni a b_1-től a b_5-ig tartó bitek felhasználásával, és a b_1 bitet kell elsőként továbbítani. Az egyéb adat szavakban az Alfanumerikus adat karaktereket az IA-5-el összhangban kell kódolni, a hét információs bit felhasználásával és egy páros paritás bitet kell az egyes karakterekhez hozzáadni. Az alfanumerikus adatokat abban a sorrendben kell továbbítani, amely szerint kiolvasásra kerülnek Egy karakter soros továbbítása esetén az alacsonyabb helyértékű bitet kell először leadni és a paritás bitet utolsóként.

1. Megjegyzés. - Az 5. sz. Nemzetközi Távíró ABC (IA-5) az Annex 10 III. Kötetében van meghatározva.

2. Megjegyzés. - A Kiegészítő adat ’A’ tartalma a következő 3.11.4.8.3.1 pontban került meghatározásra. A Kiegészítő adat ’B’ tartalmát az alábbi 3.11.4.8.3.2 pont határozza meg. A Kiegészítő adat ’C’ tartalma nemzeti felhasználásra került fenntartásra.

3.11.4.8.3.1 *A Kiegészítő adat ’A’ tartalma*. Az ”A”- Függelék A-10. táblázatában meghatározott, A1-től A4-ig terjedő kiegészítő adat szavakban lévő adat elemeket a következők szerint kell meghatározni:

a) *A Megközelítési oldalszög antenna eltolódás* a megközelítési oldalszög antenna fázis középpontja és a futópálya középvonalát magába foglaló függőleges sík közötti minimális távolságot jelenti.

b) *A Megközelítési oldalszög antenna távolsága az MLS alapponttól* azt a minimális távolságot jelenti, ami a megközelítési oldalszög antenna fázis középpontja és az MLS alappontját magába foglaló, a futópálya középvonalára merőleges függőleges sík között mérhető.

c) *A Megközelítési oldalszögnek a futópálya középvonalához viszonyított irányítottsága* a megközelítési oldalszög útirány-vezetés nulla foka és a futópálya középvonala közötti minimális szöget jelenti.

d) *A Megközelítési oldalszög antenna koordináta rendszere* azt a koordináta rendszert jelenti (síkbeli, vagy kúpos), amely szerint a megközelítési oldalszög antenna a szög adatokat kisugározza.

Megjegyzés. - Annak ellenére, hogy a fenti Szabvány egy más lehetőséget biztosító koordináta rendszer lehetővé tételét figyelembe véve került kidolgozásra, a síkbeli koordináta rendszer nincs bevezetve és a jövőbeni kivitelezése sincsen tervezve.

e) *A Megközelítési oldalszög antenna magassága* az antenna fázisközéppontjának az MLS alappontjához viszonyított függőleges helyzetét jelenti.

f) *A Megközelítési magassági szög antenna eltolódás* a magassági szög antenna fázis középpontja és a futópálya középvonalát magába foglaló függőleges sík közötti minimális távolságot jelenti.

g) *Az MLS alappont - futópálya küszöb távolság* azt a távolságot jelenti, amely az MLS alappontból a futópálya középvonalán a futópálya küszöbéig mérhető.

h) *A Megközelítési magassági szög adó antenna magassága* a magassági szög adó antenna fázis középpontjának az MLS alappontjához viszonyított függőleges helyzetét jelenti.

i) *Az MLS alappont tengerszinthez viszonyított magassága* az alappontnak a közepes tengerszinthez (mean sea level = msl) viszonyított magasságát jelenti.

j) *A Futópálya küszöbének magassága* a futópálya küszöbe és az MLS alapponthoz viszonyított középvonal metszéspontjának a függőleges helyzetét jelenti.

k) A *DME eltolódása* a DME antenna fázis középpontja és a futópálya középvonalát magába foglaló függőleges sík közötti minimális távolságot jelenti.

l) *A DME - MLS alappont távolság* a DME antenna fázis középpontja és az MLS alappontját magába foglaló, a futópálya középvonalára merőleges függőleges sík közötti minimális távolságot jelenti.

m) *A DME antenna magassága* az antenna fázis középpontjának az MLS alapponthoz viszonyított függőleges helyzetét jelenti.

n) *A Futópálya megállási végének távolsága* a futópálya megállási vége és az MLS alappont között a futópálya középvonalán mért távolságot jelenti.

o) *A Hátsó irányszektor antenna eltolódása* a hátsó irányszektor antennájának fázis középpontja és a futópálya középvonalát magába foglaló függőleges sík közötti minimális távolságot jelenti.

p) *A Hátsó irányszektor - MLS alappont távolság* a hátsó irányszektor antenna és az MLS alappontját magába foglaló, a futópálya középvonalára merőleges függőleges sík közötti minimális távolságot jelenti.

q) *A Hátsó irányszektornak a futópálya középvonalához viszonyított irányítottsága* a nulla fokos hátsó irányszektor oldalszög és a futópálya középvonala közötti minimális szöget jelenti.

r) *A Hátsó irányszektor antenna koordináta rendszere* azt a koordináta rendszert jelenti (síkbeli, vagy kúpos), amely szerint a hátsó irányszektor antenna a szög adatokat kisugározza.

Megjegyzés. - Annak ellenére, hogy a fenti Szabvány egy más lehetőséget biztosító koordináta rendszer lehetővé tételét figyelembe véve került kidolgozásra, a síkbeli koordináta rendszer nincs bevezetve és a jövőbeni kivitelezése sincsen tervezve.

s) *A Hátsó irányszektor antennájának magassága* az antenna fázis középpontjának az MLS alapponthoz viszonyított függőleges helyzetét jelenti.

Megjegyzés. - A terv szerint további Kiegészítő adat 'A' szó nem kerül majd meghatározásra.

3.11.4.8.3.2 *A Kiegészítő adat 'B' tartalma*. A Kiegészítő adat 'B' szavakat úgy kell meghatározni, ahogy ez az "A"- Függelék A-11. és A-13. táblázatában előírásra került.

3.11.4.8.3.2.1 *A Mikrohullámú leszállító rendszer / területi navigációs (MLS / RNAV) eljárás adatai.* Ahol szükséges, ott a B1-től a B39-ig terjedő kiegészítő adat szavakat kell felhasználni az MLS /RNAV eljárásokat alátámasztó adatok továbbítására. Megengedhetőnek kell lenni annak, hogy ezeket az eljárás adatokat két különálló adatbázisba osszák: az egyikbe a megközelítési oldalszög szektorba kisugárzandó adatokat, a másikba a hátsó irányszektorba kisugárzandó adatokat. Az egyes eljárások adatait annak a fedésterületi szektornak az adatbázisába kell kisugározni, amelyikbe az eljárás megkezdődik. A megszakított megközelítési eljárás adatait abba az adatbázisba kell beépíteni, amely a hozzá kapcsolódó megközelítési eljárást tartalmazza.

3.11.4.8.3.2.2 *Az Eljárások adatbázisának szerkezete*. Ahol használatos, ott az egyes eljárások adatbázisát a következők szerint kell összeállítani:

a) egy térkép / ciklikus redundancia ellenőrző (CRC) szóval kell azonosítani az adatbázis méretet, a meghatározott eljárások számát és a ciklikus redundancia ellenőrző (CRC) kódot az adatbázis érvényesítéséhez;

b) eljárás megjelölő szavakkal kell azonosítani az adatbázison belül lévő összes megnevezett megközelítési és indulási eljárást; és

c) útvonal-pont adat szavakkal kell azonosítani az eljárások útvonal-pontjai helyeit és egymás utáni sorrendjét.

Megjegyzés. - A B1-től a B39-ig terjedő Kiegészítő adat 'B' szavak szerkezete és kódolása az "A"-Függelék A-14.-től az A-17.-ig terjedő táblázataiban kerültek meghatározásra. Az MLS / RNAV eljárások kódolására vonatkozó útmutató anyag a "G"- Mellékletben került megadásra.

3.11.4.9 *Rendszer pontosság*. Az itt meghatározott pontossági szabványokat - ha nincs másképpen jelezve - 95 százalékos valószínűségi alapon kell kielégíteni.

1. Megjegyzés. - A teljes hibahatárok magukba foglalják az összes forrásból eredő hibát, azaz a légijármű fedélzeti berendezésektől, a földi berendezésektől és a terjedési hatásokból eredő hibákat.

2. Megjegyzés. - Az a cél, hogy a hibahatárokat azon repülési pályaszakaszok hosszában alkalmazzák, amelyek magukba foglalják a megközelítési vonatkoztatási pontot, vagy a hátsó irányszektor vonatkoztatási pontját. Az MLS hibák értelmezésére az ezeknek a hibáknak a repülési ellenőrzésnek megfelelő időközök során történő mérésére vonatkozó tájékoztatásokat a "G"- Melléklet 2.5.2 pontja adja meg.

3. Megjegyzés. - A megfelelő vonatkoztatási pontoktól eltérő pontokban megengedhető teljesítmény-csökkenés elfogadható hibáinak meghatározásához először a vonatkoztatási pontban meghatározott pontosságot kell átalakítani a lineáris értékekről az azoknak megfelelő szög-értékké, az antennától kiindulóan.

3.11.4.9.1 *MLS megközelítési vonatkoztatási pont*. Az MLS megközelítési vonatkoztatási pont magasságának 15 m-nek (50 láb) kell lenni. A plusz 3 m-es (10 láb) tűréshatár a megengedhető.

1. Megjegyzés. - Az MLS megközelítési vonatkoztatási pont magasságának meghatározása üzemeltetési szempontból azért fontos, hogy az akadályok feletti biztonságos útirány-vezetés, valamint a kiszolgált pálya biztonságos és hatékony használata biztosítva legyen. A 3.11.4.9.1 pontban említett magassági adatok az Annex 14-ben meghatározott 3, vagy 4 kódszámú futópályákra elfogadottak.

2. Megjegyzés. - Ugyanakkor ez a vonatkoztatási pont olyan alkalmas pontot szolgáltat, melyhez a pontosságot és egyéb működési paramétert viszonyítani lehet.

3. Megjegyzés. - Az MLS megközelítési vonatkoztatási pont fenti magassági értékeinek elérésében egy maximum 5,8 m (19 láb) függőleges távolság került a légijárműveknek a végső megközelítésre kiválasztott fedélzeti MLS antennája pályagörbéjének és a légijármű főfutója kerekeinek a futópálya küszöbe feletti legalacsonyabb pályagörbéje között alapfeltételként figyelembevételre. Az ezt a követelményt meghaladó légijárművek esetében megfelelő lépéseket lehet tenni, vagy úgy, hogy fenntartsanak egy kielégítő akadálymentességet a küszöb felett, vagy úgy, hogy szabályozzák a megengedett üzemeltetési minimumot.

3.11.4.9.2 *Az MLS hátsó irányszektorának vonatkoztatási pontja.* Az MLS hátsó irányszektor vonatkoztatási pont magasságának 15 m-nek (50 láb) kell lenni. A plusz 3 m-es (10 láb) tűréshatár a megengedhető.
Megjegyzés. - Az MLS hátsó irányszektora vonatkozási pontja meghatározásának a célja az, hogy egy olyan megfelelő pont legyen biztosítva, amelynél a funkció pontosságát és egyéb paramétereket meg lehet határozni.

3.11.4.9.3 Az útvonal-követési hibának (PFE) magába kell foglalnia az útirány-vezetési jel hibájának a fedélzeti vevő kimenetén megjelenő azon frekvencia összetevőit is, amelyek az oldalszög útirány-vezetési információkra 0,5 rad/s alatt vannak, vagy a magassági szög útirány-vezetési információkra az 1,5 rad/s alatt vannak. A kormányzási elmozdulási zajnak magába kell foglalnia az útirány-vezetési jel hibájának a fedélzeti vevő kimenetén megjelenő azon frekvencia összetevőit is, amelyek az oldalszög útirány-vezetési információkra 0,3 rad/s alatt vannak, vagy a magassági szög útirány-vezetési információkra a 0,5 rad/s alatt vannak. Az ennek a mérésnek a céljára használatos vevő kimeneti szűrőjének sarok-frekvenciája 10 rad/s.

3.11.4.9.4 *Megközelítési oldalszög útirány-vezetési funkciók.* A megközelítési vonatkoztatási pontban a megközelítési oldalszög funkciónak a következő teljesítményt kell biztosítania:

a) az útvonal-követési hiba (PFE) nem lehet nagyobb plusz, vagy mínusz 6 m-nél (20 láb);

b) az útvonal-követési zaj (PFN) nem lehet nagyobb plusz, vagy mínusz 3,5 m-nél (11,5 láb);

c) a kormányzási elmozdulási zaj (CMN) nem lehet nagyobb plusz, vagy mínusz 3,2 m-nél (10,5 láb), vagy 0,1 foknál - amelyik a kisebb.

3.11.4.9.4.1 **Ajánlás**. - A megközelítési vonatkoztatási pontban az útvonal-követési hiba (PFE) nem lehet plusz, vagy mínusz 4 m-nél (13,5 láb) nagyobb.

3.11.4.9.4.2 A vonatkoztatási pontban meghatározott lineáris pontosságot fenn kell tartani a 3.11.5.2.2.1.2 pontban meghatározott teljes futópálya fedési körzetben, kivéve ott, ahol a 3.11.4.9.4.3 pontban foglaltaknak megfelelő csökkenés megengedett.

3.11.4.9.4.3 *A megengedett csökkenés.* A megközelítési oldalszög szögbeli útvonal-követési hibájánál (PFE), útvonal-követési zajánál (PFN) és kormányzási elmozdulási zajánál (CMN) a fedésterület határai felé a következőknek megfelelő lineáris csökkenés engedhető meg:

a) *A távolságnál.* A szögértékben kifejezett útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték a futópálya küszöbétől a futópálya meghosszabbított középvonalán 37 km-es (20 tengeri mérföld) távolságnál a megközelítési vonatkoztatási pontra meghatározott érték kétszerese lehet. A kormányzási elmozdulási zaj (CMN) határértéknek 0,1 foknak kell lenni a megközelítési vonatkoztatási ponttól a futópálya meghosszabbított középvonalán - a minimális siklópálya szögön - 37 km-re (20 tengeri mérföld) mért távolságnál.

b) *Az oldalszög értéknél.* A szögértékben kifejezett útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték a plusz, vagy mínusz 40 fokos oldalszög szögnél 1,5-szerese lehet annak az értéknek, mint amennyi a megközelítési vonatkoztatási ponttól a futópálya meghosszabbított középvonalán az ugyanabban a távolságban lévő érték. A szögértékben kifejezett kormányzási elmozdulási zaj (CMN) határérték a plusz, vagy mínusz 40 fokos oldalszög szögnél 1,3-szorosa lehet annak az értéknek, mint amennyi a megközelítési vonatkoztatási ponttól a futópálya meghosszabbított középvonalán az ugyanabban a távolságban lévő érték.

c) *A magassági szög értéknél.* Az útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték nem változhat a 9 fokos magassági szögig. A szögértékben kifejezett útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték a megközelítési oldalszög antenna fázis középpontjától mért 15 fokos magassági szögön kétszerese lehet a 9 fok alatti szögre, a megközelítési vonatkoztatási ponttól az ugyanazon oldalszög értéknél, az ugyanakkora távolságban megengedett értéknél. A kormányzási elmozdulási zaj (CMN) határérték nem változhat a magassági szöggel.

d) *A maximális kormányzási elmozdulási zaj (CMN).* A maximális kormányzási elmozdulási zaj (CMN) határértéke a fedésterület semelyik részében sem haladhatja meg a 0,2 fokot.

3.11.4.9.4.3.1 **Ajánlás**. - *A maximális kormányzási elmozdulási zaj (CMN) a fedésterület semelyik részében sem haladhatja meg a 0,1 fokot.*

3.11.4.9.4.4 *A maximális szögbeli útvonal-követési hiba (PFE) és útvonal-követési zaj (PFN).* A fedésterület valamennyi részében a szögbeli hiba határértékének a következőnek kell lenni:

a) az útvonal-követési hiba (PFE) nem haladhatja meg a plusz, vagy mínusz 0,25 fokot; és

b) az útvonal-követési zaj (PFN) nem haladhatja meg a plusz, vagy mínusz 0,15 fokot.

3.11.4.9.5 *Hátsó irányszektor útirány-vezetési funkciók.* A hátsó irányszektor vonatkoztatási pontban a hátsó irányszektor oldalszög funkciónak a következő teljesítményt kell biztosítania:

a) az útvonal-követési hiba (PFE) nem lehet nagyobb plusz, vagy mínusz 6 m-nél (20 láb);

b) az útvonal-követési zaj (PFN) nem lehet nagyobb plusz, vagy mínusz 3,5 m-nél (11,5 láb);

c) a kormányzási elmozdulási zaj (CMN) nem lehet nagyobb plusz, vagy mínusz 3,2 m-nél (10,5 láb), vagy 0,1 foknál - amelyik a kisebb.

3.11.4.9.5.1 *A megengedett csökkenés.* A hátsó irányszektor szög-értékben kifejezett útvonal-követési hibájánál (PFE), útvonal-követési zajánál (PFN) és kormányzási elmozdulási zajánál (CMN) a fedésterület határai felé a következőknek megfelelő lineáris csökkenés engedhető meg:

a) *A távolságnál.* A szögértékben kifejezett útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték a fedésterület határvonalánál a futópálya meghosszabbított középvonala mentén kétszerese lehet annak az értéknek, mint ami a hátsó irányszektor vonatkoztatási pontjára meghatározott érték. A szögértékben kifejezett kormányzási elmozdulási zaj (CMN) határérték a futópálya meghosszabbított középvonalán a futópálya megállási végétől a 18,5 km-es távolságban 1,3-szerese lehet annak az értéknek, mint ami a hátsó irányszektor vonatkoztatási pontjára meghatározott érték.

b) *Az oldalszög értéknél.* A szögértékben kifejezett útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték a plusz, vagy mínusz 20 fokos oldalszög szögnél 1,5-szerese lehet annak az értéknek, mint amennyi a hátsó irányszektor vonatkoztatási ponttól a futópálya meghosszabbított középvonalán az ugyanabban a távolságban lévő érték. A szögértékben kifejezett kormányzási elmozdulási zaj (CMN) határérték a plusz, vagy mínusz 20 fokos oldalszög szögnél 1,3-szorosa lehet annak az értéknek, mint amennyi a hátsó irányszektor vonatkoztatási ponttól a futópálya meghosszabbított középvonalán az ugyanabban a távolságban lévő érték.

c) *A magassági szög értéknél.* Az útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték nem változhat a 9 fokos magassági szögig. A szögértékben kifejezett útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték a hátsó irányszektor oldalszög antenna fázis középpontjától mért 15 fokos magassági szögön kétszerese lehet a 9 fok alatti szögre, a hátsó irányszektor vonatkoztatási ponttól az ugyanazon oldalszög értéknél, az ugyanakkora távolságban megengedett értéknél. A kormányzási elmozdulási zaj (CMN) határérték nem változhat a magassági szöggel.

d) *A maximális kormányzási elmozdulási zaj (CMN)*. A maximális kormányzási elmozdulási zaj (CMN) határértéke a fedésterület egyik részében sem haladhatja meg a 0,2 fokot.

3.11.4.9.5.2 *A maximális szögbeli útvonal-követési hiba (PFE) és útvonal-követési zaj (PFN).* A fedésterület valamennyi részében a szögbeli hiba határértékének a következőnek kell lenni:

a) az útvonal-követési hiba (PFE) nem haladhatja meg a plusz, vagy mínusz 0,50 fokot; és

b) az útvonal-követési zaj (PFN) nem haladhatja meg a plusz, vagy mínusz 0,30 fokot.

3.11.4.9.6 *Magassági szög útirány-vezetési funkció*. Egy névleges 3 fokos, vagy annál alacsonyabb értékű minimális siklópálya biztosítására telepített berendezés megközelítési magassági szög funkciójának a megközelítési vonatkoztatási pontnál a következő teljesítményt kell biztosítani:

a) az útvonal-követési hiba (PFE) nem lehet nagyobb plusz, vagy mínusz 0,6 m-nél (2 láb);

b) az útvonal-követési zaj (PFN) nem lehet nagyobb plusz, vagy mínusz 0,4 m-nél (1,3 láb);

c) a kormányzási elmozdulási zaj (CMN) nem lehet nagyobb plusz, vagy mínusz 0,3 m-nél (1 láb).

3.11.4.9.6.1 *A megengedett csökkenés*. A megközelítési magassági szög szögbeli útvonal-követési hibájánál (PFE), útvonal-követési zajánál (PFN) és kormányzási elmozdulási zajánál (CMN) a fedésterület határai felé a következőknek megfelelő lineáris csökkenés engedhető meg:

a) *A távolságnál*. A szögértékben kifejezett útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték a futópálya küszöbétől a futópálya meghosszabbított középvonalán a 37 km-es (20 tengeri mérföld) távolságnál a minimális siklópályán 0,2 fok lehet. A kormányzási elmozdulási zaj CMN) határértéknek 0,1 foknak kell lenni a megközelítési vonatkoztatási ponttól a futópálya meghosszabbított középvonalán - a minimális siklópálya szögön - 37 km-re (20 tengeri mérföld) mért távolságnál.

b) *Az oldalszög értéknél*. A szögértékben kifejezett útvonal-követési hiba (PFE) határérték és az útvonal-követési zaj (PFN) határérték a plusz, vagy mínusz 40 fokos oldalszög szögnél 1,3-szerese lehet annak az értéknek, mint amennyi a megközelítési vonatkoztatási ponttól a futópálya meghosszabbított középvonalán az ugyanabban a távolságban lévő érték. A szögértékben kifejezett kormányzási elmozdulási zaj (CMN) határérték a plusz, vagy mínusz 40 fokos oldalszög szögnél 1,3-szorosa lehet annak az értéknek, mint amennyi a megközelítési vonatkoztatási ponttól a futópálya meghosszabbított középvonalán az ugyanabban a távolságban lévő érték.

c) *A magassági szögnél*. A magassági szög értékekre a minimális siklópálya, vagy a 3 fokos siklópálya felett - amelyik az alacsonyabb -, az arányos útirány-vezetési fedésterület maximális szögéig és közvetlenül a megközelítési vonatkoztatási pont felett elhelyezkedő pontban a szögbeli értékben kifejezett útvonal-követési hiba (PFE) határértéknél, az útvonal-követési zaj (PFN) határértéknél és a kormányzási elmozdulási zaj (CMN) határértéknél megengedhető az, hogy lineárisan lecsökkenjenek úgy, hogy a 15 fokos magassági szögnél a határérték a vonatkoztatási pontra meghatározott érték kétszerese legyen. A kormányzási elmozdulási zaj (CMN) értéke közvetlenül a vonatkoztatási pont felett semmilyen esetben sem haladhatja meg a plusz, vagy mínusz 0,07 fokot. A fedésterület egyéb részeiben a magassági szög szektoron belül a minimális siklópályával egyenlő magassági szögtől az arányos fedésterület maximális magassági szögig az arányos fedésterületen belül a távolságnál és az oldalszög értéknél az a) és b) pontban meghatározott értékeket kell alkalmazni.

d) Az útvonal-követési hiba (PFE), az útvonal-követési zaj (PFN) és a kormányzási elmozdulási zaj (CMN) határértékek a minimális siklópálya és a minimális siklópálya 60 százaléka között nem csökkenhetnek a magassági szöggel. A minimális siklópálya 60 százaléka alatti magassági szögek lefelé egészen a következő 3.11.5.3.2.1.2 pontban meghatározott fedésterület határvonalig és a közvetlenül a megközelítési vonatkoztatási pont alatt elhelyezkedő pontnál a szögbeli értékekben kifejezett útvonal-követési hiba (PFE) határértéknél, az útvonal-követési zaj (PFN) határértéknél és a kormányzási elmozdulási zaj (CMN) határértéknél megengedhető a megközelítési vonatkoztatási pont értékének hatszorosára való lineáris növekedés. A magassági szög szektor fedésterületének további részein a minimális siklópálya szög értéke 60 százalékával megegyező magassági szög értéktől lefelé a fedésterület határ-vonaláig, a távolsággal és az oldalszög értékben meghatározott csökkenésre az a) és b) pontban meghatározottakat kell alkalmazni. Semmilyen esetben sem megengedett az, hogy az útvonal-követési hiba (PFE) meghaladja a 0,8 fokot, vagy, hogy a kormányzási elmozdulási zaj (CMN) meghaladja a 0,4 fokot.

e) *Maximális kormányzási elmozdulási zaj (CMN)*. A minimális siklópálya 60 százalékának megfelelő értékű szög feletti magassági szögeknél a kormányzási elmozdulási zaj (CMN) határértéke a fedésterület egyik részén sem haladhatja meg a 0,2 fokot.

3.11.4.9.6.2 *A maximális szögbeli útvonal-követési hiba (PFE) és útvonal-követési zaj (PFN).* A fedésterület valamennyi részében a minimális siklópálya 60 százalékának megfelelő értékek feletti magassági szögek szögbeli hiba határértékének a következőnek kell lenni:

a) az útvonal-követési hiba (PFE) nem haladhatja meg a plusz, vagy mínusz 0,25 fokot; és

b) az útvonal-követési zaj (PFN) nem haladhatja meg a plusz, vagy mínusz 0,15 fokot.

3.11.4.9.6.3 **Ajánlás**. - *Az útvonal-követési hiba (PFE) határértékre, az útvonal-követési zaj (PFN) határértékre és a kormányzási elmozdulási zaj (CMN) határértékre szögbeli értékben kifejezett határértékek lineáris csökkenése a minimális siklópálya 60 százalékának megfelelő szög alatti szögeknél lefelé egészen a fedésterület határ-vonaláig, a megközelítési vonatkozási pontra megengedett értékek háromszorosa lehet.*

Megjegyzés. - A magassági szög szektor fedésterületének további részein a minimális siklópálya szög értéke 60 százalékával megegyező magassági szög értéktől lefelé a fedésterület határvonaláig, a távolsággal és az oldalszög értékben meghatározott csökkenésre a fenti 3.11.4.9.6.1 a) és b) pontban meghatározottakat kell alkalmazni.

3.11.4.9.6.4 **Ajánlás**. - Maximális kormányzási elmozdulási zaj (CMN). *A minimális siklópálya 60 százalékának megfelelő értékű szög feletti magassági szögeknél a kormányzási elmozdulási zaj (CMN) határértéke a fedésterület egyik részén sem haladhatja meg a 0,1 fokot.*

3.11.4.9.6.5 **Ajánlás**. - *Az útvonal-követési hiba (PFE) nem haladhatja meg a 0,35 fokot és a kormányzási elmozdulási zaj (CMN) nem haladhatja meg a 0,2 fokot.*

3.11.4.9.6.6 A 3 fokos minimális siklópályánál magasabb értékű siklópálya biztosítására telepített megközelítési magassági szög adó berendezésnek olyan szögbeli pontosságot kell biztosítani, ami nem kisebb annál, mint ami a fedésterületen belülre 3 fokos minimális siklópályát adóan telepített berendezésre előírásra került.

3.11.4.10 *Teljesítmény-sűrűség*

3.11.4.10.1 A differenciális fázis eltolásos kódolás (DPSK) a kiegészítő biztonsági-vezetési és a szög útirány-vezetés jelei teljesítmény-sűrűségének legalább a következő táblázatban megadott értékűnek kell lenni bármilyen időjárási körülmények esetén, a fedési terület bármely pontján, az alábbi 3.11.4.10.2 pontban meghatározottak kivételével.

Funkció	DPSK jelek (dBW/m^2)	DPSK jelek (dBW/m^2) antenna sugárnyaláb-szélesség			Kiegészítő biztonsági jelek (dBW/m^2)
		1°	2°	3°	
Megközelítési oldalszög útirány-vezetés	-89,5	-85,7	-79,7	-76,2	-88,0
Nagysebességű megközelítési oldalszög útirány-vezetés	-89,5	-88,0	-84,5	-81	-88,0
Hátsó irányszektor útirány-vezetés	-89,5	-88,0	-82,7	-79,2	-88,0
Megközelítési magassági szög útirány-vezetés	-89,5	-88,0	-84,5	nem alkalmazható	nem alkalmazható

Megjegyzés. - A fenti táblázat a kiegészítő biztonsági-vezetési jelek és a letapogató sugárnyaláb jeleinek minimális teljesítmény-sűrűségét határozza meg. A két jel relatív értékei a korábbi 3.11.4.6.2.5.2 pontban kerültek meghatározásra.

3.11.4.10.2 A megközelítési oldalszög útirány-vezetési szögek jelei teljesítmény-sűrűségének a fenti 3.11.4.10.1 pontban meghatározottaknál legalább a következő értékekkel nagyobbnak kell lenni:

a) 15 dB-el a megközelítési vonatkoztatási pontnál;

b) 5 dB-el az egy fokos, vagy 9 dB-el a két fokos, vagy annál nagyobb szögű sugárnyaláb szélességű antennáknál 2,5 m (8 láb) magasságban a futópálya felülete felett, az MLS alappontnál, vagy a futópálya középvonalának azon legtávolabbi pontjánál, ami az oldalszög antennától rálátási vonalban van.

1. Megjegyzés. - A futópálya felszíne közelében a megközelítési oldalszög adó berendezés általában magasabb teljesítmény-sűrűséget biztosít a szög jelekre a fenti 3.11.4.10.1 pontban meghatározottaknál azért, hogy az automata leszállási üzemeltetéseket biztosítsa. A "G"- Melléklet adja meg az antenna sugárnyaláb és a teljesítmény igényre vonatkozó tájékoztatásokat.

2. Megjegyzés. - A következő 3.11.5.2.2 és 3.11.5.3.2 pontokban leírt előírások azokat a - bonyolult földi berendezés telepítési körülményekhez - vonatkozó előírásokat adják meg, amelyek akkor szükségesek, amikor a fenti 3.11.4.10.2 pontban előírt teljesítmény-sűrűség biztosítását nem lehet megvalósítani.

3.11.5 A földi berendezések jellemzői

3.11.5.1 *Szinkronizálás és ellenőrzés*. Az időosztásos multiplex szög útirány-vezetés szinkronizálását és a korábbi, a 3.11.4.3.3 pontban felsorolt adattovábbítást ellenőrizni kell.

Megjegyzés. - A különféle MLS funkciók pontosan meghatározott ellenőrzési követelményei a következő 3.11.5.2.3 és 3.11.5.3.3 pontokban kerülnek meghatározásra.

3.11.5.1.1 *Az MLS funkciók maradék-sugárzása*. Egy MLS funkció maradék-sugárzásának azon időszak alatt, amikor más funkció kerül kisugárzásra, legalább 70 dB-el az adás alatt biztosított szint alatt kell lenni.

Megjegyzés. - Egy meghatározott funkció maradék-sugárzásának elfogadható szintje az a szint, amelynek nincs káros hatása semmilyen más funkció vételére és a berendezés telepítésétől és a légijármű helyzetétől függ.

3.11.5.2 Az oldalszög útirány-vezetést adó berendezés

3.11.5.2.1 *A letapogató sugárnyaláb jellemzői*. Az oldalszög adó földi berendezés antennájának egy olyan legyező alakú sugárzást kell előállítani, ami a vízszintes síkban keskeny és a függőleges síkban széles, és amely a letapogatást a vízszintes síkban végzi az arányos útirány-vezetési szektor határvonalai között.

3.11.5.2.1.1 *Koordináta rendszer*. Az oldalszög útirány-vezetési tájékoztatást, vagy a kúpos, vagy a síkbeli koordináta rendszerben kell kisugározni.

3.11.5.2.1.2 *Antenna sugárnyaláb szélesség*. Az antenna sugárnyaláb szélessége nem haladhatja meg a 4 fokot.

Megjegyzés. - Az a cél, hogy a detektált letapogató sugárnyaláb burkológörbéje a fedés egész területén ne lépje túl a 250 mikro-szekundumot (ez az 5 fokos sugárnyaláb szélesség megfelelője), annak érdekében, hogy a fedélzeti berendezés általi, a megfelelő szög dekódolás biztosítva legyen.

3.11.5.2.1.3 *A letapogató sugárnyaláb alakja*. A sugárnyaláb burkológörbéjének mínusz 10 dB-es pontjait a sugár középponttól legalább 0,76 sugárnyaláb szélességre, de nem többre, mint 0,96 sugárnyaláb szélességre kell eltolni.

Megjegyzés. - A leírt sugárnyaláb forma az antenna-irányítási vonalban egy megfelelő szűrőt felhasználó több-utas terjedéstől szabad környezetben értendő. A sugárnyaláb alakjára és az oldal szirmokra vonatkozó tájékoztatások a "G" Melléklet 3.1 és 3.2 pontjában találhatók.

3.11.5.2.2 Fedésterület

Megjegyzés. - Az itt meghatározott fedésterületi követelményeket bemutató diagramok a "G"- Melléklet G-5A., G-5B. és G-6. ábráin láthatók.

3.11.5.2.2.1 *Megközelítési oldalszög*. A megközelítési oldalszög adó földi berendezésnek legalább a következő légterekben kell információkat biztosítani:

3.11.5.2.2.1.1 *Megközelítési terület*.

a) Oldalirányban, egy olyan 80 fokos szektoron belül (általában az antenna-irányítási vonal körüli plusz és mínusz 40 fokig), amely a megközelítési oldalszög antenna fázis középpontjától indul ki.

b) Hosszirányban, a megközelítési oldalszög antennától 41,7 km-ig (22,5 tengeri mérföldig).

c) Függőlegesen a következők között:

1) egy olyan alsó kúpos felület, amely a megközelítési oldalszög adó antenna fázis középpontjától indul ki és felfelé hajlik addig, amíg a hosszirányú fedésterületi vonalnál a 600 m-es (2 000 láb) magasságot azon vízszintes sík felett éri el, amely az antenna fázis középpontját magába foglalja; és

2) egy olyan felső kúpos felület, amely a megközelítési oldalszög adó antenna fázis középpontjától indul ki, 15 fokos szögben felfelé hajlik és a vízszintes fölé a 6 000 m-es (20 000 láb) magasságig tart.

1. Megjegyzés. - Ahol az alsó felületen közbenső akadályok nyúlnak túl, ott az a cél, hogy nem kell útirány-vezetést biztosítani a közvetlen rálátási vonal magassága alatt.

2. Megjegyzés. - Ahol megállapították azt, hogy félrevezető információk fordulnak elő a közzétett fedésterületi szektoron kívül, és olyan megfelelő üzemeltetési eljárások nem biztosíthatók, amelyek elfogadható megoldást jelentenének, ott ezen hatások minimalizálására különböző módszerek állnak rendelkezésre. Ezek a technikai megoldások magukba foglalják az arányos útirány-vezetési szektor kiigazítását, vagy a fedésterületen-kívül jelek alkalmazását. Ezeknek a technikai megoldásoknak a felhasználására vonatkozó útmutató anyag a "G"- Melléklet 8. pontjában található.

3. Megjegyzés. - Ahol a biztosított arányos útirány-vezetési szektor kisebb annál, mint a fenti 3.11.5.2.2.1.1 a) pontban meghatározott minimális oldalirányú fedésterület, ott a fenti 3.11.4.6.2.5 pontban meghatározott kiegészítő-biztonsági vezetési jelekre van szükség.

3.11.5.2.2.1.2 *A futópálya területe.*

a) Vízszintesen a futópálya középvonalának mindkét oldalán egy olyan 45 m-es szektoron belül, amely a futópálya megállási végénél kezdődik, és a futópálya középvonalával párhuzamosan a megközelítés irányába addig terjed ki, ahol összeér az alábbi 3.11.5.2.2.1.3 pontban leírt minimális üzemeltetési fedésterülettel.

b) Függőlegesen a következők között:

1) azon vízszintes felület között, ami 2,5 m (8 láb) magasságban van a futópályának azon legtávolabbi pontja felett, ami az oldalszög adó antenna rálátási vonalában van; és

2) azon kúpos felület között, amely az oldalszög adó földi berendezés antennájánál kezdődik, és 20 fokos szögben emelkedik a vízszintes fölé a 600 m-es (2 000 láb) magasság eléréséig.

1. Megjegyzés. - A fenti b) 1) alpontban említett pont meghatározására vonatkozó tájékoztatások a "G"- Melléklet 2.3.6 pontjában vannak megadva.

2. Megjegyzés. - Az a cél, hogy a rálátási vonal alatti útirány-vezetést biztosítani lehessen addig, amíg a jel minőség ki tudja elégíteni a 3.11.4.9.4 pont pontossági követelményeit.

3.11.5.2.2.1.2.1 **Ajánlás**. - *A futópálya területén a fedésterület legalacsonyabb szintjének 2,5 m-nek (8 láb) kell lennie a futópálya középvonala felett.*

3.11.5.2.2.1.2.2 Ahol az automatikus leszállás, a leszállás utáni kifutás, vagy a felszállás alátámasztása szükséges, ott a futópálya területén a fedésterület alsó határa nem haladhatja meg a 2,5 m-t (8 láb) a futópálya középvonala felett.

Megjegyzés. - A 2,5 m-es alsó fedésterületi határértéknek az a célja, hogy minden futópályát kiszolgáljon. A 3.11.4.10.2 pontban meghatározott 2,5 m-es (8 láb) teljesítmény-sűrűség követelmény enyhítésének lehetőségére vonatkozó tájékoztatásokat a "G"- Melléklet 2.3.6 pontja adja meg.

3.11.5.2.2.1.3 *A minimális üzemeltetési fedésterület.*

a) Oldalirányban, a futópálya középvonala körüli azon plusz és mínusz 10 fokos szektoron belül, amely az MLS alappontjától indul ki.

b) Hosszirányban, a futópálya küszöbétől a megközelítés irányába a 3.11.5.2.2.1.1 b) pontban meghatározott hosszirányú fedésterületi határvonalig.

c) Függőlegesen:

1) egy olyan alsó sík között, amely magába foglalja a futópálya küszöbe feletti 2,5 m-es (8 láb) magasságú vonalat és felfelé emelkedik addig, amíg eléri a 3.11.5.2.2.1.1 c) 1) pontban meghatározott felület magasságát a hosszirányú fedésterület határvonalánál; és

2) azon felső felület között, ami a 3.11.5.2.2.1.1 c) 2) pontban meghatározásra került.

3.11.5.2.2.1.4 **Ajánlás**. - *A megközelítési oldalszög adó földi berendezésnek függőlegesen a vízszintes feletti 30 fokig kell útirány-vezetést biztosítani.*

3.11.5.2.2.1.5 A minimális arányos útirány-vezetési szektornak a következőnek kell lennie:

Megközelítési oldalszög adó antenna és a küszöb közötti távolság (AAT)	Minimális arányos lefedési terület
AAT kisebb, mint 500 m	±8°
AAT nagyobb, mint 500 m, de kisebb, mint 3 100 m	±6°
AAT nagyobb, mint 3 100 m	±4°

3.11.5.2.2.2 *Hátsó irányszektor*. A hátsó irányszektor adó földi berendezésnek legalább a következő légtérben kell információt biztosítani:

a) Vízszintesen, a futópálya középvonala körüli azon plusz, vagy mínusz 20 fokos szektoron belül, amely a hátsó irányszektor adó földi berendezés antennájától kezdődik és a megszakított megközelítés irányába a futópálya megállási végétől legalább 18,5 km-ig (10 tengeri mérföld) terjed ki.

b) Függőlegesen, a futópálya területén:

1) azon vízszintes felület között, amely 2,5 m (8 láb) magasságban van a futópálya középvonalának legtávolabbi pontja felett a hátsó irányszektor antennától rálátási vonalban; és

2) azon kúpos felület között, ami a hátsó irányszektor adó földi berendezés antennájától kezdődik és 20 fokos szögben emelkedik a vízszintes fölé a 600 m-es (2 000 láb) magasság eléréséig.

c) Függőlegesen, a hátsó irányszektor területén:

1) azon kúpos felület között, amelynek a kiinduló pontja 2,5 m (8 láb) magasságban van a futópálya megállási vége felett, és 0,9 fokkal emelkedik a vízszintes fölé; és

2) azon kúpos felület között, amely a hátsó irányszektor adó földi berendezés antennájától indul ki, és 15 fokos szögben emelkedik a vízszintes fölé a 3 000 m-es (10 000 láb) magasság eléréséig.

1. Megjegyzés. - A b) 1) alpontban említett pont meghatározására vonatkozó tájékoztatások a "G"-Melléklet 2.3.6 pontjában találhatók.

2. Megjegyzés. - Amikor a futópálya fizikai jellemzői, vagy az akadályok lehetetlenné teszik a b) és c) alpontokban meghatározott szabványok elérését, akkor az előirányzat az, hogy az útirány-vezetés nem szükséges a rálátási vonal magassága alatt.

3.11.5.2.2.2.1 **Ajánlás**. - A hátsó irányszektor adó berendezésnek a vízszintes feletti 30 fokig kell útirány-vezetést biztosítani.

3.11.5.2.2.2.2 A minimális arányos útirány-vezetési szektornak a futópálya középvonala körüli plusz, vagy mínusz 10 fokosnak kell lenni.

Megjegyzés. - Az alkalmazásra vonatkozó tájékoztatásokat a "G"- Melléklet 7.5 pontja adja meg.

3.11.5.2.3 *Ellenőrzés és vezérlés*

3.11.5.2.3.1 A megközelítési oldalszög és a hátsó irányszektor felügyelő rendszerének meg kell szűntetni a megfelelő funkció kisugárzását és egy riasztó jelzést kell leadni a kijelölt vezérlő pontokra akkor, amikor a következő körülmények valamelyike a meghatározott időtartamon túl fennáll:

a) a földi berendezés hozzájárulásával olyan változás következik be a közepes irányszög hibánál, hogy az útvonal-követési hiba (PFE) a megközelítési vonatkoztatási pontnál, vagy bármely oldalszög radiál irányában meghaladja a 3.11.4.9.4 és 3.11.4.9.5 pontokban és (az egyszerűsített mikrohullámú leszállító rendszer /MLS/ konfigurációra) a 3.11.3.4 pontban meghatározott határértékeket egy másodperc időtartamon túl, vagy (az egyszerűsített MLS konfigurációra) hat másodpercnél hosszabb időtartamon túl;

b) olyan csökkenés lép fel a kisugárzott teljesítményben, hogy az kevesebb annál, mint ami a 3.11.4.10.1 és 3.11.4.6.2.5.2 pontokban meghatározott követelmények kielégítéséhez szükséges egy másodpercnél hosszabb időtartamon keresztül;

c) egy olyan hiba van a bevezető jelszakasz differenciális fázis eltolásos kódolási adásaiban, ami bármely egy másodperces időtartam alatt egynél többször előfordul;

d) egy olyan hiba van egy meghatározott oldalszög funkció időosztásos multiplex szinkronizálásában, hogy a 3.11.4.3.2 pontban meghatározott követelmények nincsenek teljesítve, és ez a körülmény egy másodpercnél hosszabb ideig fennáll.

Megjegyzés. - Az útmutató anyagot a "G"- Melléklet 6. pontja adja meg.

3.11.5.2.3.2 A felügyelő rendszer tervezésének és működésének olyannak kell lenni, hogy meg kell szűntetnie a sugárzást és le kell adnia a riasztó jelzést a kijelölt vezérlő pontokra, magának a felügyelő rendszernek a meghibásodása esetén is.

3.11.5.2.3.3 Az olyan időtartam, amely alatt a hibás útirány-vezetési információ kisugárzásra kerül - beleértve a nulla sugárzási időtartamokat is - nem haladhatja meg a 3.11.5.2.3.1 pontban meghatározott időtartamokat. A hiba elhárításának az elsődleges földi berendezés visszakapcsolásával történő megkísérlésének, vagy a tartalék földi berendezésre történő átkapcsolásnak ezen idő alatt be kell fejeződni. Ha a hiba nem kerül a megengedett időn belül elhárításra, akkor a sugárzást le kell állítani. A lekapcsolás után a szolgáltatás visszaállítását nem lehet megkísérelni addig, amíg 20 másodperc el nem telik.

3.11.5.2.4 *A mikrohullámú leszállító rendszer /MLS/ oldalszög szolgáltatás teljességi /integritás/ és folyamatossági követelményei*

3.11.5.2.4.1 Annak a valószínűsége, hogy nem kerülnek pontatlan irányvezetési jelek kisugárzásra a II. és III. kategóriájú üzemeltetési fel-használásra tervezett MLS oldalszögön végrehajtott bármely leszállásra, nem lehet kevesebb 1 - 0,5 x 10^{-9}-nél.

3.11.5.2.4.2 **Ajánlás**. - Annak a valószínűsége, hogy nem kerülnek pontatlan irányvezetési jelek kisugárzásra az I. kategóriájú üzemeltetési felhasználásra tervezett MLS oldalszögön végrehajtott bármely leszállásra, nem lehet kevesebb 1 - 0,5 x 10^{-7}-nél.

3.11.5.2.4.3 Annak a valószínűsége, hogy a kisugárzott irány-vezetési jel nem kerül elvesztésre, nagyobb kell, hogy legyen, mint:

a) 1 - 2 x 10^{-6} bármely 15 másodperces időtartamban a II. és a III.A. kategóriájú üzemeltetési felhasználásra tervezett mikrohullámú leszállító rendszer oldalszögénél (ez a leállások közötti átlagos 2000 órás idővel egyenlő); és

b) 1 - 2 x 10^{-6} bármely 30 másodperes időtartamban a III. kategóriájú üzemeltetések teljes tartományára felhasználásra tervezett mikrohullámú leszállító rendszer oldalszögénél (ez a leállások közötti átlagos 4000 órás idővel egyenlő).

3.11.5.2.4.4 **Ajánlás**. - *Annak a valószínűsége, hogy a kisugárzott irányvezetési jel nem kerül elvesztésre, meg kell, hogy haladja az 1 - 4 x 10^{-6}-t bármely 15 másodpercben az I. kategóriájú üzemeltetési felhasználásra tervezett mikrohullámú leszállító rendszer oldalszögénél (ez a leállások közötti átlagos 1000 órás idővel egyenlő).*

Megjegyzés. - A szolgáltatás teljességi és folyamatossági követelményeire vonatkozó útmutató anyag a "G"- Melléklet 11. pontjában került megadásra.

3.11.5.2.5 *A földi berendezés pontossága*

3.11.5.2.5.1 A földi berendezésnek a közepes irányszög hibához való hozzájárulása nem haladhatja meg a plusz, vagy mínusz 3 m-rel (10 láb) egyenértékű hibát az MLS megközelítési referencia pontnál.

3.11.5.2.5.2 **Ajánlás**. - *A földi berendezésnek a kormányzási elmozdulási zajhoz (CMN) való hozzájárulása a referencia pontnál nem haladhatja meg az 1 métert (3,3 láb), vagy a 0,03 fokot - amelyik a kisebb -, 95 százalékos valószínűségi alapon figyelembe véve.*

1. Megjegyzés. - Ez egy berendezés hiba, és ez nem foglal magába semmilyen terjedési hatást.

2. Megjegyzés. - Az ennek a paraméternek a mérésére vonatkozó útmutató anyagot a "G"- Melléklet 2.5.2 pontjában lehet megtalálni.

3.11.5.2.6 Telepítés

1. Megjegyzés. - Nem cél az, hogy az MLS telepítését korlátozzuk akkor, amikor az oldalszög adó földi berendezést nem lehet a futópálya középvonalának meghosszabbításában telepíteni.

2. Megjegyzés. - Az oldalszög adó antennák kritikus és érzékenységi területeire vonatkozó útmutató anyagot a "G"- Melléklet 4.2 pontja adja meg.

3.11.5.2.6.1 Szabályszerűen a megközelítési oldalszög adó földi berendezés antennáját a futópálya középvonalának meghosszabbításában kell elhelyezni, a futópálya megállási végén túl, és úgy kell beállítani, hogy a nulla fokos iránysáv vonalat magába foglaló függőleges sík az MLS megközelítési referencia alappontot is magába foglalja. Az antenna elhelyezésének meg kell felelni az Annex 14 Szabványok és Ajánlott Gyakorlatok által meghatározott biztonságos akadálymentességnek.

3.11.5.2.6.2 A hátsó irányszektor oldalszög adó földi berendezés antennáját szabályszerűen a futópálya középvonalának meghosszabbításában kell elhelyezni a futópálya küszöbe előtti végénél, és úgy kell beállítani, hogy a nulla fokos iránysáv vonalat magába foglaló függőleges sík magába foglalja a hátsó irányszektor referencia alappontját.

3.11.5.3 Magassági szög útirány-vezetést adó berendezés

3.11.5.3.1 *A letapogató sugárnyaláb jellemzői*. A magassági szög adó földi berendezés antennájának egy olyan legyező alakú sugárzást kell előállítani, ami a függőleges síkban keskeny és a vízszintes síkban széles, és amely a letapogatást függőlegesen végzi az arányos útirány-vezetési szektor határvonalai között.

3.11.5.3.1.1 *Koordináta rendszer*. A megközelítési magassági szög útirány-vezetési tájékoztatást a kúpos koordináta rendszerben kell kisugározni.

3.11.5.3.1.2 *Antenna sugárnyaláb szélesség*. Az antenna sugárnyaláb szélessége nem haladhatja meg a 2,5 fokot.

3.11.5.3.1.3 *A letapogató sugárnyaláb alakja*. A sugárnyaláb burkológörbéjének mínusz 10 dB-es pontjait a sugár középponttól legalább 0,76 sugárnyaláb szélességre, de nem többre, mint 0,96 sugárnyaláb szélességre kell eltolni.

Megjegyzés. - A leírt sugárnyaláb forma az antenna-irányítási vonalban egy megfelelő szűrőt felhasználó több-utas terjedéstől szabad környezetben értendő. A sugárnyaláb alakjára és az oldalszirmokra vonatkozó tájékoztatások a "G"- Melléklet 3.1 és 3.2 pontjában találhatók.

3.11.5.3.2 *Fedésterület*

Megjegyzés. - Az itt meghatározott fedésterületi követelményeket bemutató diagramok a "G"- Melléklet G-10A. ábráján láthatók.

3.11.5.3.2.1 *Megközelítési magassági szög*. A megközelítési magassági szög adó földi berendezésnek legalább a következő légterekben kell információkat biztosítani.

3.11.5.3.2.1.1 *Megközelítési terület*.

a) Oldalirányban, egy olyan szektoron belül, amely a magassági szög adó antenna fázis középpontjából indul ki és a szögbeli kiterjedése legalább a megközelítési oldalszög adó földi berendezés által a hosszirányú fedésterület határáig biztosított arányos útirány-vezetési szektorral megegyező.

b) Hosszirányban, a magassági szög adó antennától a megközelítés irányába a küszöbtől 37 km-es (20 tengeri mérföld) távolságig.

c) Függőlegesen a következők között:

1) egy olyan alsó kúpos felület, amely a magassági szög adó antenna fázis középpontjától indul ki és felfelé hajlik addig, amíg a hosszirányú fedésterületi vonalnál a 600 m-es (2 000 láb) magasságot azon vízszintes sík felett éri el, amely az antenna fázis középpontját magába foglalja; és

2) egy olyan felső kúpos felület, amely a magassági szög adó antenna fázis középpontjától indul ki, 7,5 fokos szögben felfelé hajlik és a vízszintes fölé a 6 000 m-es (20 000 láb) magasságig tart.

Megjegyzés. - Amikor a megközelítési terület fizikai jellemzői lehetetlenné teszik az a), b) és c) 1) alpontokban meghatározott szabványok elérését, akkor az az előirányzat, hogy az útirány-vezetés nem szükséges a rálátási vonal alatt.

3.11.5.3.2.1.1.1 **Ajánlás**. - A megközelítési magassági szög adó földi berendezésnek arányos útirány-vezetést kell biztosítani a vízszintes feletti 7,5 foknál nagyobb szögekre akkor, amikor az üzemeltetési követelmények kielégítésére szükséges.

3.11.5.3.2.1.2 *A minimális üzemeltetési fedésterület.*

a) Oldalirányban, azon a szektoron belül, amely az MLS alappontból indul ki egy, a futópálya középvonala körüli plusz és mínusz 10 fokon belül;

b) Hosszirányban, az MLS alappontból a futópálya küszöbének irányában 75 m-től (250 láb) a 3.11.5.3.2.1.1 b) pontban meghatározott külső fedésterületi határvonalig.

c) Függőlegesen, a 3.11.5.3.2.1.1 c) 2) alpontban meghatározott felső felület és a következők közül a magasabb között:

1) azon felület, amelynek a pontjai a 2,5 méteres (8 láb) magasságban vannak a futópálya felett; vagy

2) azon sík, amely az MLS alappontból indul ki, és felfelé emelkedően a hosszirányú fedésterület határvonalánál éri el a 3.11.5.3.2.1.1 c) 1) alpontban meghatározott felület magasságát.

Megjegyzés. - A megközelítési magassági szög vízszintes sugárzási karakterisztikájára vonatkozó tájékoztatásokat a "G"- Melléklet 3.3 pontja adja meg.

3.11.5.3.3 *Ellenőrzés és vezérlés*

3.11.5.3.3.1 A megközelítési magassági szög felügyelő rendszerének meg kell szűntetni a megfelelő funkció kisugárzását és egy riasztó jelzést kell leadni a kijelölt vezérlő pontokra akkor, amikor a következő körülmények valamelyike a meghatározott időtartamon túl fennáll:

a) a földi berendezés hozzájárulásával olyan változás következik be a közepes siklópálya hibánál, hogy az útvonal-követési hiba (PFE) a megközelítési vonatkoztatási pontnál, vagy a közzétett megközelítési eljárásokhoz kapcsolódó bármely siklópálya szögön meghaladja a 3.11.4.9.6 pontban, valamint (az egyszerűsített mikrohullámú leszállító rendszer /MLS/ konfigurációra) a 3.11.3.4 pontban meghatározott határértékeket egy másodperc időtartamon túl, vagy (az egyszerűsített MLS konfigurációra) a 6 másodpercnél hosszabb időtartamon túl;

b) olyan csökkenés lép fel a kisugárzott teljesítményben, hogy az kevesebb annál, mint ami a 3.11.4.10.1 pontban meghatározott követelmények kielégítéséhez szükséges egy másodpercnél hosszabb időtartamon keresztül;

c) egy olyan hiba van a bevezető jelszakasz differenciális fázis eltolásos kódolás adásaiban, ami bármely egy másodperces időtartam alatt egynél többször előfordul;

d) egy olyan hiba van egy meghatározott magassági szög funkció időosztásos multiplex szinkronizálásában, hogy a 3.11.4.3.2 pontban meghatározott követelmények nincsenek teljesítve, és ez a körülmény egy másodpercnél hosszabb ideig fennáll.

Megjegyzés. - Az útmutató anyagot a "G"- Melléklet 6. pontja adja meg.

3.11.5.3.3.2 A felügyelő rendszer tervezésének és működésének olyannak kell lenni, hogy meg kell szűntetnie a sugárzást és le kell adnia a riasztó jelzést a kijelölt vezérlő pontokra, magának a felügyelő rendszernek a meghibásodása esetén is.

3.11.5.3.3.3 Az az időtartam, amely alatt a hibás útirány-vezetési információ kisugárzásra kerül - beleértve a nulla sugárzási időtartamokat is - nem haladhatja meg a 3.11.5.3.3.1 pontban meghatározott időtartamokat. A hiba elhárításának az elsődleges földi berendezés visszakapcsolásával történő megkísérlésének, vagy a tartalék földi berendezésre történő átkapcsolásnak ezen idő alatt be kell fejeződni. Ha a hiba nem kerül a megengedett időn belül elhárításra, akkor a sugárzást le kell állítani.

A lekapcsolás után a szolgáltatás visszaállítását nem lehet megkísérelni addig, amíg 20 másodperc el nem telik.

3.11.5.3.4 *A mikrohullámú leszállító rendszer /MLS/ megközelítési magassági szög szolgáltatás teljességi /integritás/ és folyamatossági követelményei*

3.11.5.3.4.1 Annak a valószínűsége, hogy nem kerülnek pontatlan irányvezetési jelek kisugárzásra a II. és III. kategóriájú üzemeltetési felhasználásra tervezett MLS megközelítési magassági szögön végrehajtott bármely leszállásra, nem lehet kevesebb 1 - 0,5 x 10^{-9}-nél.

3.11.5.3.4.2 **Ajánlás**. - *Annak a valószínűsége, hogy nem kerülnek pontatlan irányvezetési jelek kisugárzásra az I. kategóriájú üzemeltetési felhasználásra tervezett MLS megközelítési magassági szögön végrehajtott bármely leszállásra, nem lehet kevesebb 1 - 0,5 x 10^{-7}-nél.*

3.11.5.3.4.3 Annak a valószínűsége, hogy a kisugárzott irány-vezetési jel nem kerül elvesztésre, nagyobb kell, hogy legyen, mint 1 - 2 x 10-6 bármely 15 másodperes időtartamban a II. és III. kategóriájú üzemeltetési felhasználásra tervezett mikrohullámú leszállító rendszer megközelítési magassági szögénél (ez a leállások közötti átlagos 2000 órás idővel egyenlő).

3.11.5.3.4.4 **Ajánlás**. - *Annak a valószínűsége, hogy a kisugárzott irányvezetési jel nem kerül elvesztésre, meg kell, hogy haladja az 1 - 4 x 10^{-6}-t bármely 15 másodpercben az I. kategóriájú üzemeltetési felhasználásra tervezett mikrohullámú leszállító rendszer megközelítési magassági szögénél (ez a leállások közötti átlagos 1000 órás idővel egyenlő).*

Megjegyzés. - A szolgáltatás teljességi és folyamatossági követelményeire vonatkozó útmutató anyag a "G"- Melléklet 11. pontjában került megadásra.

3.11.5.3.5 *A földi berendezés pontossága*

3.11.5.3.5.1 A földi berendezésnek a közepes siklópálya hiba útvonal-követési hiba (PFE) értékéhez való hozzájárulása nem haladhatja meg a plusz, vagy mínusz 0,3 m-rel (1 láb) egyenértékű hibát a megközelítési vonatkoztatási pontnál.

3.11.5.3.5.2 **Ajánlás**. - *A földi berendezésnek a kormányzási elmozdulási zajhoz (CMN) való hozzájárulása a vonatkoztatási pontnál nem haladhatja meg a 0,15 métert (0,5 láb), 95 százalékos valószínűségi alapon figyelembe véve.*

1. Megjegyzés. - Ez egy berendezés hiba, és ez nem foglal magába semmilyen terjedési hatást.

2. Megjegyzés. - Az ennek a paraméternek a mérésére vonatkozó útmutató anyagot a "G"- Melléklet 2.5.2 pontjában lehet megtalálni.

3.11.5.3.6 *Telepítés*

Megjegyzés. - A magassági szög adó antennák kritikus területeire vonatkozó útmutató anyagot a "G"- Melléklet 4.2 pontja adja meg.

3.11.5.3.6.1 A megközelítési magassági szög adó földi berendezés antennáját a futópálya mellett kell elhelyezni. Az antennák telepítését az Annex 14 Szabványok és Ajánlott Gyakorlatok akadály-mentességi követelményeinek megfelelően kell telepíteni.

3.11.5.3.6.2 A megközelítési magassági szög adó földi berendezés antennáját úgy kell telepíteni, hogy a minimális siklópálya aszimptótája a futópálya küszöbénél keresztezze az MLS megközelítési vonatkoztatási pontját.

.11.5.3.6.2.1 **Ajánlás**. - *A minimális siklópálya szögnek szabályszerűen 3 foknak kell lenni, és nem haladhatja meg a 3 fokot, csak ott, ahol az akadálymentességi követelmények kielégítése más eszközökkel megvalósíthatatlan*.

Megjegyzés. - Az a cél, hogy a 3 fokosnál magasabb szögű minimális siklópálya kiválasztása inkább üzemeltetési szempontból kerüljön meghatározásra, és ne technikai tényezőként.

3.11.5.3.6.2.2 **Ajánlás**. A megközelítési magassági szög adó földi berendezés antennáját úgy kell telepíteni, hogy annak a pontnak a magassága, amely a minimális siklópálya dekódolt útirány-vezetési jelének felel meg, a futópálya küszöbe felett ne haladja meg a 18 métert (60 láb).

Megjegyzés. A magassági szög adó antennának a futópálya középvonalától való oldalirányú merőleges elhelyezése okozza azt, hogy a minimális siklópálya magassági szög útirány-vezetés a megközelítési vonatkoztatási pont felett lesz.

3.11.5.3.6.3 **Ajánlás**. - Amikor ILS és MLS egyidejűleg szolgálja ki ugyanazt a futópályát, akkor az ILS vonatkozási pontnak és az MLS megközelítési vonatkoztatási pontjának 1 m-es (3 láb) tűréshatáron belül egybe kell esni.

1. Megjegyzés. - Az a cél, hogy ez az ajánlás csak akkor legyen alkalmazható, amikor az ILS vonatkozási pont kielégíti a korábbi 3.1.5.1.4 és 3.1.5.1.5 pontok magassági előírásait.

2. Megjegyzés. - Az együtt telepített MLS / ILS elhelyezésére vonatkozó tájékoztatásokat a "G"- Melléklet 4.1 pontja adja meg.

3.11.5.4 *Adat fedésterület és ellenőrzés*

1. Megjegyzés. - Az adatok alkalmazására vonatkozó útmutató anyagot a "G"- Melléklet 2.7 pontja adja meg.

2. Megjegyzés - Az elsőrendű fontosságú adatok az alap adatok és az elsőrendű fontosságú kiegészítő adatok az A1, A2, A3 és A4 kiegészítő adatszavakban leadott adatok.

3.11.5.4.1 Alap adatok

3.11.5.4.1.1 Az 1., 2., 3., 4. és a 6. alap adat szavakat a teljes megközelítési oldalszög útirány-vezetési fedésterületi szektorba ki kell sugározni.

Megjegyzés. - Az alap adat szavak összeállítása az "A"- Függelék A-7. táblázatában került megadásra.

3.11.5.4.1.2 Ahol a hátsó irányszektor funkció biztosítva van, ott a 4., 5., és 6. alap adat szavakat a teljes megközelítési oldalszög útirány-vezetési és hátsó irányszektor fedésterületi szektorba ki kell sugározni.

3.11.5.4.2 *Kiegészítő adatok*

3.11.5.4.2.1 Az 'A1'., 'A2'., és az 'A3'. kiegészítő adat szavakat a teljes megközelítési oldalszög útirány-vezetési fedésterületi szektorba ki kell sugározni.

3.11.5.4.2.2 Ahol a hátsó irányszektor funkció biztosítva van, ott az 'A3'. és 'A4'. kiegészítő adat szavakat a teljes megközelítési oldalszög útirány-vezetési és hátsó irányszektor fedésterületi szektorba ki kell sugározni.

Megjegyzés. - A 'B42'. és 'B43'. kiegészítő adat szavakat külön-külön az 'A1'. és az 'A4'. helyen kell sugározni az olyan alkalmazási területeken, amelyek szükségessé teszik az oldalszög antenna átfordítását az 'A1'. és 'A4'. szóban rendelkezésre álló egyenes vonalú távolságon kívül.

3.11.5.4.2.3 Amikor biztosításra kerül, akkor a kiegészítő adat 'B' szavakat a teljes megközelítési oldalszög szektorban ki kell sugározni, kivéve azt, hogy a hátsó irányszektor eljárásainak adatbázisát magukba foglaló szavakat a teljes hátsó irányszektorba kell kisugározni.

3.11.5.4.2.4 **Ajánlás**. - *Ha a hátsó irányszektor funkció biztosítva van, akkor a megfelelő kiegészítő adat 'B' szavakat is ki kell sugározni.*

Megjegyzés. - A kiegészítő adat szavak összeállítása az "A"- Függelék A-10., A-12. és A-15. táblázatában került megadásra.

3.11.5.4.3 *Ellenőrzés és vezérlés*

3.11.5.4.3.1 A felügyelő rendszernek egy riasztó jelzést kell leadni a kijelölt vezérlő pontra akkor, ha a kisugárzott teljesítmény kisebb annál, mint ami a korábbi 3.11.4.10.1 pontban meghatározott differenciális fázis eltolásos kódolás (DPSK) követelményének kielégítéséhez szükséges.

3.11.5.4.3.2 Ha a megközelítési oldalszög fedésterületre kisugárzott alap adatokban az észlelt hiba legalább két egymást követő vett mintában előfordul, akkor ezeknek az adatoknak, valamint a megközelítési oldalszög és magassági szög funkcióknak a sugárzását meg kell szűntetni.

3.11.5.4.3.3 Ha a hátsó irányszektor fedésterületre kisugárzott alap adatokban az észlelt hiba legalább két egymást követő vett mintában előfordul, akkor ezeknek az adatoknak, valamint a hátsó irányszektor funkcióknak a sugárzását meg kell szűntetni.

3.11.5.5 *Távolságmérő berendezés*

3.11.5.5.1 A DME információt legalább azon a teljes fedésterületen belül kell biztosítani, amelyben a megközelítési és hátsó irányszektor útirány-vezetés rendelkezésre áll.

3.11.5.5.2 **Ajánlás**. - *A DME információt a teljes 360°-os irányszögben biztosítani kell, ha az üzemeltetési szempontból szükséges.*

Megjegyzés. - A DME földi berendezés telepítési helye a futópálya hosszától, a futópálya profiljától és a helyi terepfelszíntől függ. A DME földi berendezés telepítésére vonatkozó útmutató anyag a "C"- Melléklet 7.1.6 pontjában és a "G"- Melléklet 5. pontjában került megadásra.

3.11.6 A légijármű fedélzeti berendezés jellemzői

3.11.6.1 *Szög és adat funkciók*

3.11.6.1.1 *Pontosság*

3.11.6.1.1.1 Ahol a differenciális fázis eltolásos kódolás /DPSK/ és a letapogató sugárnyaláb jel teljesítmény-sűrűsége megfelel annak, ami a fenti 3.11.4.10.1 pontban meghatározásra került, ott a légijármű fedélzeti berendezésének képesnek kell lenni arra, hogy vegye a jeleket és bármilyen olyan dekódolt szög jelet, amelynek a kormányzási elmozdulási zaja (CMN) nem haladja meg a 0,1 fokot, kivéve azt, hogy a hátsó irányszektor útirány-vezetési funkciónál a kormányzási elmozdulási zaj (CMN) nem haladhatja meg a 0,2 fokot.

1. Megjegyzés. - Az a cél, hogy azok az alap és kiegészítő adat szavak, amelyek a kívánt üzemeltetéshez elengedhetetlen információkat tartalmaznak, egy idő-perióduson belül dekódolásra kerüljenek, és olyan integritással, amely megfelel a tervezett alkalmazásnak.

2. Megjegyzés. - A szög útirány-vezetési és az adat funkciók "begyűjtésére"és érvényesítésére vonatkozó tájékoztatások a "G"- Melléklet 7.3 pontjában kerültek megadásra.

3.11.6.1.1.2 Ahol a kisugárzott jel teljesítmény-sűrűsége elég magas ahhoz, hogy a légijármű fedélzeti vevő zaj-hozzájárulása jelentéktelenné váljon, ott a légijármű fedélzeti berendezés nem csökkentheti semelyik dekódolt szög útirány-vezetési jel pontosságát az útvonal-követési hibánál (PFE) plusz, vagy mínusz 0,017 foknál nagyobb értékben, vagy a kormányzási elmozdulási zajnál (CMN) plusz, vagy mínusz 0,015 foknál (oldalszög) és plusz, vagy mínusz 0,01 foknál (magassági szög) nagyobb értékben.

3.11.6.1.1.3 Abból a célból, hogy a pontos útirány-vezetés a futópálya felülete feletti 2,5 méternél (8 láb) elérhető legyen, a légijármű fedélzeti berendezésnek 0,04 foknál kisebb kormányzási elmozdulási zajt (CMN) kell létrehozni a fenti 3.11.4.10.2 b) alpontban megadott teljesítmény-sűrűség mellett.

3.11.6.1.2 *Dinamika tartomány*

3.11.6.1.2.1 A légijármű fedélzeti berendezésnek képesnek kell lenni a jelek "begyűjtésére" és a fenti 3.11.6.1.1.2 pontban lévő teljesítményt ki kell, hogy elégítse ott, ahol bármely kisugárzott jel teljesítmény-sűrűségének az értéke a fenti 3.11.4.10.1 pontban meghatározott minimum érték és az azon feletti maximum mínusz 14,5 dBW/m^2 érték között van.

3.11.6.1.2.2 A vevő teljesítménye nem csökkenhet a meghatározott értékeken kívülre akkor, amikor a fenti 3.11.6.1.2.1 pontban meghatározott maximális különbségű szintek állnak fenn az egyes funkciók jel teljesítmény-sűrűsége között.

3.11.6.1.3 *A vevő berendezés szög adat kimeneti szűrőjének jellemzői*

3.11.6.1.3.1 A szinuszos bemeneti frekvenciáknál a vevő kimeneti szűrői nem gerjeszthetnek a szög adatokban olyan amplitúdó ingadozást, vagy fáziskésést, ami 20 százaléknál nagyobb mértékben meghaladná azt, mint ami egy 10 rad/s sarok-frekvenciájú egypólusú aluláteresztő szűrővel elérhető.

Megjegyzés. - A csak vizuális kijelző egységek működtetésére szánt vevő kimeneteknél hasznos lehet megfelelő további szűrés. A kimenő adatok szűrésére vonatkozó kiegészítő tájékoztatások a "G" Melléklet 7.4.2 pontjában kerültek megadásra.

3.11.6.1.4 *Szomszéd csatorna hamis vétel*. A fenti 3.11.6 pontban meghatározott vevő teljesítményt kell kielégíteni akkor, amikor a kívánt jelek és az adott frekvenciára központosítottan egy 150KHz-es sávszélességben lévő szomszédos csatorna jelek között az arány egyenlő, vagy nagyobb, mint a következő pontokban ismertetett jel/zaj viszony (SNR) értékek:

a) ahogy az X1- Táblázatban megadásra kerültek, amikor a kívánt földi állomásról vett teljesítmény-sűrűség egyenlő, vagy nagyobb, mint ami az Y- Táblázatban megadásra került, vagy

b) ahogy az X2- Táblázatban megadásra kerültek, amikor a kívánt földi állomásról vett teljesítmény-sűrűség a 3.11.4.10.1.pontban meghatározott minimális sűrűségi teljesítmény értékek és az Y-Táblázatban megadott értékek között van.

Y- Táblázat

Funkció	*Sávszélesség (2. Megjegyzés)*		
	1°	*2°*	*3°*
Megközelítési oldalszög útirány-vezetés	-69,8 dBW/m^2	-63,8 dBW/m^2	-60,2 dBW/m^2
Nagysebességű megközelítési útirány-vezetés	-74,6 dBW/m^2	-69,5 dBW/m^2	-65 dBW/m^2
Megközelítési magassági szög útirány-vezetés	-71 dBW/m^2	-65 dBW/m^2	nem alkalmazható
Hátsó irányszektor	nem alkalmazható (lásd 4. Megjegyzést)	nem alkalmazható (lásd 4. Megjegyzést)	nem alkalmazható (lásd 4. Megjegyzést)

X1- Táblázat

Funkció	*Adat*	*SNR (lásd 1. Megjegyzést) Sávszélesség (2. Megjegyzés)*		
		1°	*2°*	*3°*
Megközelítési oldalszög útirány-vezetés	5 dB	24,7 dB	30,7 dB	34,3 dB
Nagysebességű megközelítési útirány-vezetés	5 dB	19,9 dB	26 dB	29,5 dB
Megközelítési magassági szög útirány-vezetés	5 dB	23,5 dB	29,5 dB	nem alkalmazható
Hátsó irányszektor (lásd 4. Megjegyzést)	5 dB	5,2 dB	11,2 dB	14,8 dB

X2- Táblázat

Funkció	*Adat*	*SNR (lásd 1. Megjegyzést) Sávszélesség (2. Megjegyzés)*		
		1°	*2°*	*3°*
Megközelítési oldalszög útirány-vezetés	5 dB	8,2 dB	14,3 dB	17,8 dB
Nagysebességű megközelítési útirány-vezetés	5 dB	3,5 dB	9,5 dB	13 dB
Megközelítési magassági szög útirány-vezetés	5 dB	3,5 dB	9,5 dB	nem alkalmazható
Hátsó irányszektor (lásd 4. Megjegyzést)	5 dB	5,2 dB	11,2 dB	14,8 dB

1. Megjegyzés – Amikor a kisugárzott kívánt jel teljesítmény-sűrűsége elég nagy ahhoz, hogy a légijármű fedélzeti vevő zaj-hozzájárulása jelentéktelenné váljon, ott a 3.11.6.1.1 pontban megállapított, a légijárműnek a magassági szög és a megközelítési oldalszög útirány-vezetéséhez (a hátsó irányszektorhoz nem) tartozó kormányzási elmozdulási zaj (CMN) hozzájárulását csökkenteni kell, összehasonlítva azzal a kormányzási elmozdulási zaj (CMN) hozzájárulással, amikor a kisugárzott kívánt jel teljesítmény-sűrűsége a minimumon van, ahogy a 3.11.4.10.1 pontban megadásra került, és ezért a minimális jel/zaj (SNR) viszony értékek magasabbak.

2. Megjegyzés – A sugárszélességek által kijelölt egymás mellett levő pontok között a kapcsolat lineáris.

3. Megjegyzés – Ezeket a jel/zaj (SNR) viszony értékeket végig tartani kell a "G"- Melléklet 9.3 pontjában ismertetett frekvencia elkülönítési kritérium alkalmazása során.

4. Megjegyzés – Mivel nincs változás a hátsó irányszektor útirány-vezetés pontosságában, amikor a légijármű fedélzeti vevő zaj jelentéktelennek vehető, ezért ugyanazok a jel/zaj (SNR) viszony értékek alkalmazandók a hátsó irányszektornál.

* Ezek a csatornák kizárólag nemzeti kiosztásra vannak fenntartva.

** Ezeket a csatornákat másodlagos alapon lehet nemzeti kiosztásra felhasználni. Ezen csatornák tartalékolásának elsődleges oka az, hogy védelmet biztosítsunk a másodlagos légtérellenőrző radar (SSR) rendszerek részére.

*** A 108,0 MHz-nek ILS szolgáltatási frekvenciaként való kijelölése nem tervezett. A hozzá kapcsolódó DME a 17X sz. üzemeltetési csatornát kényszerhelyzeti alkalmazásra lehet kijelölni.

B - táblázat: A megengedhető DME/P hibák

Hely	Szabvány	Mód	Útvonal-követési hiba (PFE)	Kormányzási elmozdulási zaj (CMN)

	4. karakter		6			I_{25}-I_{30}
	PARITÁS		2	Lásd az 1. Megjegyzést		I_{31} - I_{32}

MEGJEGYZÉSEK. –

1. Paritás bitként az I_{31} és az I_{32} került kiválasztásra az egyenlőségek kielégítésére:

$I_{13} + I_{14} ..... + I_{29} + I_{30} + I_{31}$ = PÁRATLAN
$I_{14} + I_{16} + I_{18} ..... + I_{28} + I_{30} + I_{32}$ = PÁRATLAN

2. Az állapot-jelző bit kódolása:

0 = funkció nincs kisugározva, vagy az ellenőrző üzemmódban kerül kisugárzásra (navigációs célra nem megbízható);

1 = a funkció szabályos üzemmódban kerül kisugárzásra (az Alap adat szó 2.-ben a hátsó irányszektor állapota is azt jelzi, hogy a hátsó irányszektor adása következik).

3. Ezek a bitek későbbi felhasználásra vannak fenntartva. Az egyik lehetséges felhasználás a hátsó irányszektor elhajlási lépték tényezőjének meghatározása.

4. Az Alap adat 4. és 6. szava mindkét, a megközelítési oldalszög és a hátsó irányszektor fedésterületére kisugárzásra kerül akkor, amikor a hátsó irányszektor útirány-vezetés biztosítva van, úgy, hogy közben az egyes fedésterületi szektorokban az adások közötti maximális meghatározott idő megmarad.

5. Az Alap adat 5. szava mindkét, a megközelítési oldalszög és a hátsó irányszektor fedésterületére kisugárzásra kerül akkor, amikor a hátsó irányszektor útirány-vezetés biztosítva van, úgy, hogy közben az egyes fedésterületi szektorokban az adások közötti maximális meghatározott idő megmarad.

6. Ezek a bitek a nagysebességű adásoknál való későbbi felhasználásra vannak fenntartva.

7. Az I_{21} és az I_{22} kódolása:

I_{21}	I_{22}	
0	0	A DME válaszadó üzemképtelen, vagy nem áll rendelkezésre.
1	0	Csak kezdeti megközelítési (IA) mód, vagy DME/N áll rendelkezésre.
0	1	Végső megközelítési (FA) mód, Szabvány 1. áll rendelkezésre.
1	1	Végső megközelítési (FA) mód, Szabvány 2. áll rendelkezésre.

8. A tényleges sugárnyaláb szélesség kódolt értéke (ahogy az a 3. Fejezet 3.11.1 pontjában meghatározásra került) a közelebbi 0,5 fokra van kerekítve.

9. Az I_{29} kódolása:

0 = impulzus biztonsági távolság jel,
1 = letapogatási biztonsági távolság jel.

10. A bevezető jelszakasz 12 adatbitjét egy 0,832 milliszekundumos (13 órajel impulzus) időtartamú vivőhullám előzi meg a vivőhullám begyűjtése céljából (lásd az A-1. táblázatot).

11. A letapogatási határérték nagyobb az arányos útirány-vezetési szektornak az Alap adat 1. és 5. szavában megadott határvonalánál, ahogy az a 3.11.4.5.1 pontban leírásra került.

12. Az összes tartalék bit NULLA-ra van állítva.

A-8. táblázat: A kiegészítő adat funkció időzítése

(lásd a 3.11.4.3.4 pontot)

Esemény	Az esemény idő-rés kezdési ideje	
	15,625 KHz-es órajel impulzus (szám)	Idő (milliszekundum)
Bevezető jelszakasz (előtag)	0	0
Cím továbbítás (I_{13} – I_{20} bitek)	25	1.600
Adat továbbítás (I_{21} – I_{69} bitek)	33	2.112
Paritás továbbítás (I_{70} – I_{76} bitek)	82	5.248
Vége funkció (fedélzeti)	89	5.696
Vége védő-idő; vége funkció (földi)		5.900

MEGJEGYZÉS. - Paritás bitként az I_{19} és az I_{20} került kiválasztásra az egyenlőségek kielégítésére:

$I_{13} + I_{14} + I_{15} + I_{16} + I_{17} + I_{18} + I_{19}$ = PÁROS

$I_{14} + I_{16} + I_{18} + I_{20}$ = PÁROS

MEGJEGYZÉSEK. –

1. Az I_{70}-től az I_{76}-ig terjedő paritás bitek kerültek kiválasztásra a következő egyenlőségek kielégítésére.

Az I_{70} bitre:

PÁROS = $(I_{13} + ... + I_{18}) + I_{20} + I_{22} + I_{24} + I_{25} + I_{28} + I_{29} + I_{31} + I_{32} + I_{33} + I_{35} + I_{36} + I_{38} + I_{41} + + I_{44} + I_{45} + I_{46} + I_{50} + (I_{52} + ... + I_{55}) + I_{58} + I_{60} + I_{64} + I_{65} + I_{70}$

Az I_{71} bitre:

PÁROS = $(I_{14} + ... + I_{19}) + I_{21} + I_{23} + I_{25} + I_{26} + I_{29} + I_{30} + I_{32} + I_{33} + I_{34} + I_{36} + I_{37} + I_{39} + I_{42} + + I_{45} + I_{46} + I_{47} + I_{51} + (I_{53} + ... + I_{56}) + I_{59} + I_{61} + I_{65} + I_{66} + I_{71}$

Az I_{72} bitre:

PÁROS = $(I_{15} + ... + I_{20}) + I_{22} + I_{24} + I_{26} + I_{27} + I_{30} + I_{31} + I_{33} + I_{34} + I_{35} + I_{37} + I_{38} + I_{40} + I_{43} + I_{46} + I_{47} + I_{48} + I_{52} + (I_{54} + ... + I_{57}) + I_{60} + I_{62} + I_{66} + I_{67} + I_{72}$

Az I_{73} bitre:

PÁROS = $(I_{16} + ... + I_{21}) + I_{23} + I_{25} + I_{27} + I_{28} + I_{31} + I_{32} + I_{34} + I_{35} + I_{36} + I_{38} + I_{39} + I_{41} + I_{44} + + I_{47} + I_{48} + I_{49} + I_{53} + (I_{55} + ... + I_{58}) + I_{61} + I_{63} + I_{67} + I_{68} + I_{73}$

Az I_{74} bitre:

PÁROS = $(I_{17} + ... + I_{22}) + I_{24} + I_{26} + I_{28} + I_{29} + I_{32} + I_{33} + I_{35} + I_{36} + I_{37} + I_{39} + I_{40} + I_{42} + I_{45} + + I_{48} +I_{49} + I_{50} + I_{54} + (I_{56} + ... + I_{59}) + I_{62} + I_{64} + I_{68} + I_{69} + I_{74}$

Az I_{75} bitre:

PÁROS = $(I_{13} + ... + I_{17}) + I_{19} + I_{21} + I_{23} + I_{24} + I_{27} + I_{28} + I_{30} + I_{31} + I_{32} + I_{34} + I_{35} + I_{37} + I_{40} + I_{43} +I_{44} + I_{45} + I_{49} + (I_{51} + ... + I_{54}) + I_{57} + I_{59} + I_{63} + I_{64} + I_{69} + I_{75}$

Az I_{76} bitre:

PÁROS = $I_{13} + I_{14} +... + I_{75} + I_{76}$

2. Az antenna koordináta rendszerének kódja 0 = kúpos.

3. A negatív számok kódolásának konvenciója a következő:

A legnagyobb helyértékű bit az előjel bit, ez:
0 = pozitív
1 = negatív

A további bitek az abszolút értéket képviselik.

Az antenna helyzetének konvenciója a következő:

Az MLS megközelítési vonatkoztatási alapponttól az MLS alappont felé nézve a pozitív szám a futópálya középvonalától jobbra helyzetet (oldalirányú ofszet), vagy a futópálya feletti helyzetet (függőleges ofszet), vagy a futópálya megállási vége irányába való helyzetet (hossz-irányú távolság) jelenti.

Az irányítottság konvenciója a következő:
Felülnézetből, a pozitív szám jelenti az óramutató járásával megegyező irányú körforgást a futópálya középvonalától a megfelelő nulla-fokos oldalszögig.

4. Az A3. adatszó mindkét, a megközelítési oldalszög és a hátsó irányszektor fedésterületére kisugárzásra kerül akkor, amikor a hátsó irányszektor útirány-vezetés biztosítva van, úgy, hogy közben az egyes fedésterületi szektorokban az adások közötti maximális meghatározott idő megmarad.

5. Az A4. adatszó mindkét, a megközelítési oldalszög és a hátsó irányszektor fedésterületére kisugárzásra kerül akkor, amikor a hátsó irányszektor útirány-vezetés biztosítva van, úgy, hogy közben az egyes fedésterületi szektorokban az adások közötti maximális meghatározott idő megmarad.

6. A bevezető jelszakasz (előtag) 12 adatbitjét egy 0,832 milliszekundumos (13 órajel impulzus) időtartamú vivőhullám előzi meg a vivőhullám begyűjtése céljából (lásd az A-1. táblázatot).

7. Lásd az A-12. táblázat B42. és B43. adatszavait, amelyek azokra az alkalmazásokra kerültek meghatározásra, amelyek a 20,47°-nál nagyobb oldalszög antenna elfordulás leadását teszik szükségessé az A1. adat-elemben az oldalszögre és az A4.-ben a hátsó irányszektorra. Egy olyan berendezésnél, amelynek a megközelítési oldalszög elfordulása a 20,47°-nál nagyobb, a B42. adatszót kell leadni az A1. helyett. Egy olyan berendezésnél, amelynek a hátsó irányszektor elfordulása a 20,47°-nál nagyobb, a B43. adatszót kell leadni az A4. helyett.

8. Az összes tartalék bit NULLA-ra van állítva.

A-11. táblázat: A kiegészítő adat B szavak meghatározása

(lásd a 3.11.4.8.3.2 pontot)

Megjegyzés. - Az MLS / RNAV eljárásokat alátámasztó kiegészítő adat B szavak meghatározását az A-13. táblázat adja meg.

a) *Az MLS alappont földrajzi szélessége* az MLS alappont földrajzi szélességének koordinátája, - ahogy az a Geodéziai Világrendszer (WGS)-84 vonatkoztatási ellipszoidja, koordináta rendszere és a hozzá kapcsolódó alappontok szerint meghatározásra került.

b) *Az MLS alappont földrajzi hosszúsága* az MLS alappont földrajzi hosszúságának koordinátája, ahogy az a fenti a) adatszónál említettel azonos referencia ellipszoid, koordináta rendszer és alappont szerint meghatározásra került.

c) *Az MLS alappont függőleges koordinátája* az MLS alappont függőleges koordinátája, ahogy az a fenti a) adatszónál említettel azonos referencia ellipszoid, koordináta rendszer és alappont szerint meghatározásra került.

Megjegyzés. - Annak ellenére, hogy a WGS-84 ICAO Szabványként a földrajzi szélességet és hosszúságot jelző geográfiai koordinátaként jóváhagyásra került, a függőleges WGS-84 koordináták bevezetése még eldöntetlen. Ennek a bevezetéséig egy, a közepes tengerszintre (mean sea level = msl) vonatkoztatott tengerszinthez viszonyított magasságot lehet a továbbiakban is használni.

d) *A megközelítési oldalszögnek a földrajzi Északhoz viszonyított irányítottsága* a vízszintes síkban az óramutató járásával megegyező irányban a Földrajzi Északtól a megközelítési oldalszög antennától kiinduló nulla-fokos megközelítési oldalszögig mért szöget jelenti. A mért szög csúcspontjának a megközelítési oldalszög antenna fázis középpontjának kell lenni.

e) *Futópálya látástávolság (RVR)* a műszerrel mért RVR értéket jelenti a földetérési pontnál, a futópálya közepénél és a megállási végénél, a tendencia jelzésével együtt, úgy biztosítva, hogy az megfeleljen az Annex 3 4. Fejezetében leírtaknak.

f) *Talajszél* a szélsebességet és a szélirányt (mágneses) jelenti, úgy biztosítva, hogy az megfeleljen az Annex 3 4. Fejezetében leírtaknak.
g) *A Megközelítési oldalszög antenna ofszet-je* a megközelítési oldalszög antenna fázis középpontja és a futópálya középvonalát magába foglaló függőleges sík közötti minimális távolságot jelenti.

h) *A Megközelítési oldalszög antenna távolsága az MLS alapponttól* azt a minimális távolságot jelenti, ami a megközelítési oldalszög antenna fázis középpontja és az MLS alappontját magába foglaló, a futópálya középvonalára merőleges függőleges sík között mérhető.

i) *A Megközelítési oldalszögnek a futópálya középvonalához viszonyított irányítottsága* a nulla fokos megközelítési oldalszög útirány-vezetési radiál és a futópálya középvonala közötti minimális szöget jelenti.

j) *A Megközelítési oldalszög antenna magassága* az antenna fázis középpontjának az MLS alappontjához viszonyított függőleges helyzetét jelenti.

k) *A Hátsó irányszektor antenna ofszet-je* a hátsó irányszektor antennájának fázis középpontja és a futópálya középvonalát magába foglaló függőleges sík közötti minimális távolságot jelenti.

l) *A Hátsó irányszektor antenna - MLS alappont távolság* a hátsó irányszektor antenna és az MLS alappontját magába foglaló, a futópálya középvonalára merőleges függőleges sík közötti minimális távolságot jelenti.

m) *A Hátsó irányszektornak a futópálya középvonalához viszonyított irányítottsága* a nulla fokos hátsó irányszektor oldalszög és a futópálya középvonala közötti minimális szöget jelenti.

n) *A Hátsó irányszektor antennájának magassága* az antenna fázis-középpontjának az MLS alapponthoz viszonyított függőleges helyzetét jelenti.

o) *Az elsődleges futópálya száma* az elsődleges futópálya számot jelenti, ahogy ez az Annex 14 I. Kötetének 5. Fejezetében meghatározásra került.

p) *Az elsődleges futópálya betűjele* az elsődleges futópálya betűjelét jelenti ott, ahol az a párhuzamos futópályák közötti megkülönböztetés céljára használatos, ahogy ez az Annex 14 I. Kötetének 5.Fejezetében meghatározásra került.

q) *A másodlagos futópálya száma* a másodlagos futópálya számot jelenti, ahogy ez az Annex 14 I. Kötetének 5.Fejezetében meghatározásra került.

r) *A másodlagos futópálya betűjele* a másodlagos futópálya betűjelét jelenti ott, ahol az a párhuzamos futópályák közötti megkülönböztetés céljára használatos, ahogy ez az Annex 14 I. Kötetének 5.Fejezetében meghatározásra került.

s) *Magassági szög útirány-vezetés a másodlagos futópályára* azt jelenti, hogy van, vagy nincs olyan magassági szög útirány-vezetés, amely a másodlagos futópályára felhasználható, és ha van, akkor azt, hogy az közvetlenül eredeti szögként felhasználható-e, vagy egy kiszámított siklópályát tesz szükségessé.

t) *Minimális siklópálya a másodlagos futópályára* a másodlagos futópálya középvonalában lévő legalacsonyabb süllyedési szöget jelenti.

u) *A Megközelítési oldalszögnek a másodlagos futópálya középvonalához viszonyított irányítottsága* a nulla fokos megközelítési oldalszög útirány-vezetési radiál és a másodlagos futópálya középvonala közötti minimális szöget jelenti.

v) *A másodlagos futópálya küszöbének X koordinátája* a másodlagos futópálya küszöbe és az elsődleges futópályának az MLS alappontját magába foglaló középvonalára merőleges függőleges sík közötti minimális távolságot jelenti.

w) *A másodlagos futópálya küszöbének Y koordinátája* a másodlagos futópálya küszöbe és az elsődleges futópálya középvonalát magába foglaló függőleges sík közötti minimális távolságot jelenti.

x) *A másodlagos futópálya küszöbének Z koordinátája* a másodlagos futópálya küszöbének az MLS alappont feletti magasságát jelenti.

y) *A másodlagos futópálya küszöbének keresztezési magassága* a másodlagos futópálya felett azt a magasságot jelenti, amelynél a számított siklópálya a küszöböt keresztezi.

z) *Látszólagos oldalszög - másodlagos futópálya küszöb távolság* a másodlagos futópálya küszöbének attól a ponttól való távolságát jelenti, amelyet az arra a futópályára vezető oldalirányú útirány-vezetés kiindulási pontjának tekintenek.

Megjegyzés. - Ezt a távolságot az MLS vevővel ahhoz hasonló módon lehet felhasználni, mint a megközelítési oldalszög antenna - futópálya küszöb távolságot az oldalirányú eltérési lépték-tényező megállapításához.

MEGJEGYZÉSEK. –

1. Az I_{70}-től az I_{76}-ig terjedő paritás bitek kerültek kiválasztásra a következő egyenlőségek kielégítésére.

Az I_{70} bitre:

PÁROS = $(I_{13} + ... + I_{18}) + I_{20} + I_{22} + I_{24} + I_{25} + I_{28} + I_{29} + I_{31} + I_{32} + I_{33} + I_{35} + I_{36} + I_{38} + I_{41} + + I_{44} + I_{45} + I_{46} + I_{50} + (I_{52} + ... + I_{55}) + I_{58} + I_{60} + I_{64} + I_{65} + I_{70}$

Az I_{71} bitre:

PÁROS = $(I_{14} + ... + I_{19}) + I_{21} + I_{23} + I_{25} + I_{26} + I_{29} + I_{30} + I_{32} + I_{33} + I_{34} + I_{36} + I_{37} + I_{39} + I_{42} + + I_{45} + I_{46} + I_{47} + I_{51} + (I_{53} + ... + I_{56}) + I_{59} + I_{61} + I_{65} + I_{66} + I_{71}$

Az I_{72} bitre:

PÁROS = $(I_{15} + ... + I_{20}) + I_{22} + I_{24} + I_{26} + I_{27} + I_{30} + I_{31} + I_{33} + I_{34} + I_{35} + I_{37} + I_{38} + I_{40} + I_{43} + + I_{46} + I_{47} + I_{48} + I_{52} + (I_{54} + ... + I_{57}) + I_{60} + I_{62} + I_{66} + I_{67} + I_{72}$

Az I_{73} bitre:

PÁROS = $(I_{16} + ... + I_{21}) + I_{23} + I_{25} + I_{27} + I_{28} + I_{31} + I_{32} + I_{34} + I_{35} + I_{36} + I_{38} + I_{39} + I_{41} + I_{44} + + I_{47} + I_{48} + I_{49} + I_{53} + (I_{55} + ... + I_{58}) + I_{61} + I_{63} + I_{67} + I_{68} + I_{73}$

Az I_{74} bitre:

PÁROS = $(I_{17} + ... + I_{22}) + I_{24} + I_{26} + I_{28} + I_{29} + I_{32} + I_{33} + I_{35} + I_{36} + I_{37} + I_{39} + I_{40} + I_{42} + I_{45} + + I_{48} +I_{49} + I_{50} + I_{54} + (I_{56} + ... + I_{59}) + I_{62} + I_{64} + I_{68} + I_{69} + I_{74}$

Az I_{75} bitre:

PÁROS = $(I_{13} + ... + I_{17}) + I_{19} + I_{21} + I_{23} + I_{24} + I_{27} + I_{28} + I_{30} + I_{31} + I_{32} + I_{34} + I_{35} + I_{37} + I_{40} + + I_{43} +I_{44} + I_{45} + I_{49} + (I_{51} + ... + I_{54}) + I_{57} + I_{59} + I_{63} + I_{64} + I_{69} + I_{75}$

Az I_{76} bitre:

PÁROS = $I_{13} + I_{14} +... + I_{75} + I_{76}$

2. A negatív számok kódolásának konvenciója a következő:
A legnagyobb helyértékű bit az előjel bit, ez:
0 = pozitív
1 = negatív

A további bitek az abszolút értéket képviselik.

Az antenna helyzetének konvenciója a következő:

Az MLS megközelítési vonatkoztatási alapponttól az MLS alappont felé nézve a pozitív szám a futópálya középvonalától jobbra helyzetet (oldalirányú ordináta), vagy a futópálya feletti helyzetet (függőleges ordináta), vagy a futópálya megállási vége irányába való helyzetet (hosszirányú távolság) jelenti.

Az irányítottság konvenciója a következő:

Felülnézetből, a pozitív szám jelenti az óramutató járásával megegyező irányú körforgást a futópálya középvonalától a megfelelő nulla-fokos oldalszögig.

A geodéziai koordináták konvenciója a következő:

A pozitív számok az északi földrajzi szélességet, vagy a keleti földrajzi hosszúságot jelentik.
A negatív számok a déli földrajzi szélességet, vagy a nyugati földrajzi hosszúságot jelentik.

3. Az egyes futópálya látástávolság (RVR) értékek továbbításánál felhasznált tizedik és tizenegyedik bit a tendencia tájékoztatások biztosítására használatos. A kódolás konvenciója a következő:

	Tizedik bit	Tizenegyedik bit
Kikapcsolva	0	0
Csökkenő	1	0
Egyenlő	0	1
Növekvő	1	1

4. Amikor használatos, akkor az Alap adat B43. szava mindkét, a megközelítési oldalszög és a hátsó irányszektor fedésterületére kisugárzásra kerül akkor, amikor a hátsó irányszektor útirány-vezetés biztosítva van, úgy, hogy közben az egyes fedésterületi szektorokban az adások közötti maximális meghatározott idő megmarad.

5. A B42. és B43. Adat szavak azokra az alkalmazásokra kerültek meghatározásra, amelyek a 20,47^o-nál nagyobb oldalszög antenna elfordulás leadását teszik szükségessé az A1. adat-elemben az oldalszögre és az A4.-ben a hátsó irányszektorra. Egy olyan berendezésnél, amelynek a megközelítési oldalszög elfordulása a 20,47^o-nál nagyobb, a B42. adatszót kell leadni az A1. helyett. Egy olyan berendezésnél, amelynek a hátsó irányszektor elfordulása a 20,47^o-nál nagyobb, a B43. adatszót kell leadni az A4. helyett.

6. A bevezető jelszakasz (előtag) 12 adatbitjét egy 0,832 milliszekundumos (13 órajel impulzus) időtartamú vivőhullám előzi meg a vivőhullám begyűjtése céljából (lásd az A-1. táblázatot).

7. A kódolás konvenciója a következő:

0 = nincs betű
1 = R (jobb)
2 = C (középső)
3 = L (bal)

8. A kódolás konvenciója a következő:

0 = nincs biztosítva
1 = eredeti magassági szög útirány-vezetés
2 = számított siklópálya
3 = kód nem engedélyezett

9. Az összes tartalék bit NULLA-ra van állítva.

10. A 0 futópálya szám jelölés a helikopter üzemeltetésre vonatkozik.

A-13. táblázat: Az MLS /RNAV eljárások adatbázisára vonatkozó Kiegészítő adat B elemek meghatározása

(lásd a 3.11.4.8.3.2 pontot)

a) *A megközelítési oldalszög eljárás leírók száma* az azon összes megnevezett megközelítési és indulási eljárás számát jelenti, amelyről eljárás leíró szavak kerülnek a megközelítési oldalszög fedésterületi szektorba kisugárzásra.

Megjegyzés. - A megszakított megközelítések nincsenek beszámítva, mivel azoknál nem használnak eljárás leíró szavakat. Az elsődleges futópályára vezető kiszámított középvonalú eljárások akkor kerülnek beszámításra, amikor egy eljárás leírás leadásra kerül, még akkor is, ha a hozzá kapcsolódó útvonalpont adat nem kerül leadásra a B1-től a B39-ig tartó kiegészítő szavakban.

b) *A hátsó irányszektor oldalszög eljárás leírók száma* az azon összes megnevezett megközelítési és indulási eljárás számát jelenti, amelyről eljárás leíró szavak kerülnek a hátsó irányszektor fedésterületi szektorba kisugárzásra.

Megjegyzés. - A megszakított megközelítések nincsenek beszámítva, mivel azoknál nem használnak eljárás leíró szavakat.

c) *Az utolsó megközelítési oldalszög adatbázis szó* annak a B1-től a B39-ig tartó tartományon belüli utolsó kiegészítő adat szónak a címzés kódját jelenti, amely megközelítési oldalszög fedésterületi szektorba leadásra került úgy, ahogy annak a szónak az I_{13}-tól az I_{18}-ig terjedő bitjei meghatározták.

d) *Az első hátsó irányszektor adatbázis szó* annak a B1-től a B39-ig tartó tartományon belüli utolsó kiegészítő adat szónak a címzés kódját jelenti, amely hátsó irányszektor fedésterületi szektorba leadásra került úgy, ahogy annak a szónak az I_{13}-tól az I_{18}-ig terjedő bitjei meghatározták.

e) *Megközelítési oldalszög Ciklikus Redundancia Ellenőrző (CRC) kód* megközelítési oldalszög eljárás adatbázisa ciklikus redundancia ellenőrző kódjának együtthatóját jelenti.

f) *Hátsó irányszektor Ciklikus Redundancia Ellenőrző (CRC) kód* a hátsó irányszektor eljárás adatbázisa ciklikus redundancia ellenőrző kódjának együtthatóját jelenti.

g) *A kisugárzott B42. szó* azt jelenti, hogy a B42 kiegészítő adat szó leadásra került-e az A1 szó helyett.

h) *A kisugárzott A4. szó* azt jelenti, hogy az A4 kiegészítő adat szó leadásra került-e.

i) *A kisugárzott B43. szó* azt jelenti, hogy a B43 kiegészítő adatszó leadásra került-e.

j) *Hátsó irányszektor térkép / Ciklikus Redundancia Ellenőrzés (CRC) jelzés* azt jelenti, hogy a B39 kiegészítő adat szó hátsó irányszektor térkép / Ciklikus Redundancia Ellenőrzés szóként, vagy egy megközelítési oldalszög útvonalpont adatszóként került-e leadásra.

k) *Alap jelzés* egy megközelítési eljárás elsőként átrepülendő útvonalpontjának nevét, vagy az indulási eljárás utolsóként átrepülendő útvonalpontjának nevét jelenti. A névnek egy öt betűs - az 5.sz. Nemzetközi Távíró ABC b1-től b5-ig terjedő bitjeinek megfelelően leadott - karakterből kell állni.

l) *Érvényesség jelzés* a megközelítési, vagy indulási eljárás módosítási szintjét jelenti. Az érvényesség jelzésnek egy, az 1-től a 9-ig terjedő számnak kell lenni.

m) *Útvonal jelzés* az alap jelzés által megnevezett útvonalponttól kiinduló, vagy oda vezető útvonalat jelenti. Az útvonal jelzésnek egy egyedülálló egy-betűs - az 5.sz. Nemzetközi Távíró ABC b1-től b5-ig terjedő bitjeinek megfelelően leadott - karakterből kell állni. Az "I" és "O" betűket nem lehet felhasználni. A rendelkezésre álló 24 útvonal jelzés mindegyikét csak egyszer lehet kiosztani a megközelítési oldalszög és a hátsó irányszektor eljárás leírási szavak kombinált sorozatában.

Megjegyzés. - Az MLS / RNAV üzemeltetések útvonal jelzései egyedülálló kijelölési korlátozásai egy kiindulási pontot jelentenek a szabványos útvonal kijelölési gyakorlattal, ami azért szükséges, hogy növeljük az eljárás kiválasztás integritását, és csökkentsük a légijármű-vezetők munkaterhelését.

n) *A futópálya száma* a futópálya számát jelenti az Annex 14 I. Kötete 5. Fejezetében meghatározottaknak megfelelően.

o) *A futópálya betűjele* a futópálya betűjelét jelenti az Annex 14 I. Kötete 5. Fejezetében meghatározottaknak megfelelően ott, ahol a párhuzamos futópályák közötti megkülönböztetésre alkalmazzák.

p) *Az eljárás típusa* azt jelenti, hogy az eljárás egy megközelítési eljárás, vagy egy indulási eljárás.

q) *Az első útvonalpont mutató* a megközelítési oldalszög adatbázison belül, vagy a hátsó irányszektor oldalszög adatbázison belül az útvonalpont meghatározási adatokban az eljárás első kódolt útvonalpontja sorrendi helyzetét jelenti.

r) *X koordináta* az adott útvonalpontnak a meghatározott koordináta rendszer szerinti X koordinátáját jelenti.

s) *Y koordináta követő* azt jelenti, hogy az Y koordináta egy adott útvonalpontra továbbításra kerül-e, vagy sem. Ha az Y koordináta nem kerül továbbításra, akkor az Y koordinátát nullának kell elfogadni.

t) *Y koordináta* az adott útvonalpontnak a meghatározott koordináta rendszer szerinti Y koordinátáját jelenti.

u) *Z koordináta követő* azt jelenti, hogy a Z koordináta egy adott útvonalpontra továbbításra kerül-e, vagy sem.

v) *Z koordináta* az adott útvonalpontnak a meghatározott koordináta rendszer szerinti Z koordinátáját jelenti.
w) *Következő szakasz / adatmező azonosító* azt jelenti, hogy egy adott eljárás következő szakasza egyenes, vagy ívelt, és jelzi azt, hogy melyik adatmezőben következnek az útvonalpont koordinátái.

x) *A futópálya küszöb útvonalpont magassága* az elsődleges futópálya küszöb útvonalpontjának a futópálya küszöbe feletti magasságát jelenti.

y) *Látszólagos oldalszög - útvonalpont távolság* egy, a nem az elsődleges futópálya küszöbéhez vezető megközelítési eljárásban az oldalirányú útirány-vezetés kiinduló pontjának tekintett ponttól az útvonalpontig mért távolságot jelenti.

Megjegyzés. - Ezt a távolságot az MLS vevő hasonló módon tudja felhasználni, mint a megközelítési oldalszög antenna - futópálya küszöb távolságot az eljárás oldalirányú eltérési lépték-tényezője megállapításához.

z) *A következő útvonalpont mutató* a megközelítési oldalszög adatbázison belül, vagy a hátsó irányszektor oldalszög adatbázison belül az útvonalpont meghatározási adatokban az eljárás következő kódolt útvonalpontja sorrendi helyzetét jelenti.

Megjegyzés. - A következő útvonalpont mutatót fel lehet használni annak lehetővé tételére, hogy egy, vagy több olyan útvonalpontot megosszanak, amely kifejezetten egy másik eljárás részeként van meghatározva. A megosztott útvonalpontok a megközelítési eljárások utolsó pontjai és a megszakított megközelítési, valamint az indulási eljárások kiinduló pontjai.

aa) *A megszakított megközelítés mutatója* a megközelítési oldalszög adatbázison belül, vagy a hátsó irányszektor oldalszög adatbázison belül az útvonalpont meghatározási adatokban a kapcsolódó megszakított megközelítési eljárás első kódolt (utolsó átrepült) útvonalpontja sorrendi helyzetét jelenti.

A-14. táblázat: Az MLS / RNAV eljárás adatbázisának szerkezete

MEGJEGYZÉSEK. –

1. Az "M" paraméter azon megnevezett megközelítési és indulási eljárások számát jelenti, amelyek a megközelítési oldalszög fedésterületi szektoron belül kezdődnek. Az "N" paraméter azon megnevezett megközelítési és indulási eljárások számát jelenti, amelyek a hátsó irányszektor fedésterületi szektoron belül kezdődnek.

2. Egy hátsó irányszektor adatbázis nélküli berendezésnél az összes szót a B39-ig fel lehet használni a megközelítési oldalszög adatbázis részére.

Megjegyzés - Az adat típusa digitális

MEGJEGYZÉSEK. –

1. A szó számoknál használt változók annak felelnek meg, ami az A-14. számú táblázatban használatos.

2. Ez az adatmező az A-9. táblázatnak megfelelően van kódolva, az I_{13}-tól az I_{18}-ig tartó bitek felhasználásával. Ebben a táblázatban az I_{25} bit adja át az A-9. táblázat I_{13} bitjének információját és az kerül először kisugárzásra.

3. A CRC kód a két polinom modulo 2-vel való osztásának a maradékát, az R(x)-t foglalja magába:

$$\left[\frac{x^{32}\ M(x)}{G(x)}\right]_{\text{mod } 2} = Q(x) + \frac{R(x)}{G(x)}$$

Az M(x) az az információs adatmező, amely az alábbiakban meghatározott megközelítési oldalszög, vagy hátsó irányszektor adatbázisból áll, a bevezető jelszakaszok, a címek, a paritás bitek és a CRC kód bitjeinek kivételével. A kiegészítő adat szavaknál ezek az I_{21}-től az I_{69}-ig terjedő bitek és az alap adat szavaknál az I_{13}-tól az I_{30}-ig terjedő bitek. Az adatbázis a következő - a jegyzékben megadott sorrendű - adat szavakból áll:

Megközelítési oldalszög adatbázis	Hátsó irányszektor adatbázis
B1 (I_{21}-től I_{30}-ig, I_{63}-tól I_{69}-ig)	B(b)-től B38-ig
B2-től B(a)-ig	B39 (I_{21}-től I_{30}-ig, I_{63}-tól I_{69}-ig bitek)
B40, B41	B40, B41, A3
A1, vagy B42, A2, A3	A4, vagy B43 (ha kisugárzásra került)
A4, vagy B43 (ha kisugárzásra került)	Alap adat 6. szó
Alap adat 6. szó	

Az M(x) az x^{32}-el van megszorozva, amely 32 nulla bitet tesz hozzá az osztandó végéhez.

A G(x) a kódgeneráló polinom, a következők szerint meghatározva:

$$G(x) = x^{32} + x^{31} + x^{14} + x^{13} + x^{9} + x^{8} + x^{4} + x^{3} + x + 1$$

A Q(x) az osztás hányadosa.

A CRC kód, az R(x), az x^{31} együtthatóval I_{31} bitként és az x^0 együtthatóval I_{62}-es bitként kerül továbbításra.

4. A kódolás konvenciója a következő:
0 = nem
1 = igen

5. A betű karakterek úgy kerülnek kódolásra, ahogy az a 3.11.4.8.3 pontban a B1-től a B39-ig terjedő adat szavakra meghatározásra került.

6. A kódolás konvenciója a következő:
0 = nincs betű
1 = R (jobb)
2 = C (középső)
3 = L (bal)

7. A kódolás konvenciója a következő:
0 = megközelítési eljárás
1 = indulási eljárás

8. Az útvonalpont mutató számok egymás utáni számozással a megközelítési oldalszög, vagy hátsó irányszektor adatbázisában lévő valamennyi útvonalpontra kijelölésre kerülnek. Ha egy útvonalpont van az elsődleges futópálya küszöbére úgy kódolva, hogy csak a futópálya küszöb keresztezési magasságot tartalmazza, akkor ez ki van hagyva az útvonalpont mutató sorozatából.

9. Ebben az adatmezőben a nulla érték azt jelenti, hogy az eljárás egy olyan számított középvonalú eljárás, amely a kiegészítő adatszavakban az A1 (vagy B42), A2, A3 és az A4 (vagy B43) szavakban megadott adatokon alapszik.

10. Az útvonalpont meghatározások változó hosszúságúak és egymás után vannak kódolva, anélkül, hogy alkalmazkodnának a szavak határaihoz. Az útvonalpont meghatározások között a tartalék bitek használata nem megengedett. Az utolsó útvonalpont szavának végén lévő bármilyen tartalék biteket nullára kell állítani. Egy megközelítési eljárás útvonalpont meghatározásai abban a sorrendben kerülnek kódolásra, ahogy a légijármű végigrepüli az eljárást. A megszakított megközelítésre, vagy az indulásra az útvonalpont meghatározások a fordított sorrendbe vannak kódolva. Azok a megszakított megközelítési, vagy indulási útvonalpontok, amelyek nem közösek a megközelítési útvonalpontokkal, az adatbázisban lévő utolsó megközelítési útvonalpont után vannak kódolva.

11.Azoknál a berendezéseknél, amelyeknek nincs hátsó irányszektoruk, a B39-es kiegészítő szót fel lehet használni útvonalpont adatszóként a megközelítési oldalszög adatbázisban. A B39-es szó I_{69}-es bitje használatos a szó alkalmazásának jelzésére. A kódolás konvenciója a következő:
0 = a B39 szó egy útvonalpont adatszó
1 = a B39 szó a hátsó irányszektor térkép / CRC szó

12. Az összes tartalék bit nullára van állítva.

13. Az I_{70}-től az I_{76}-ig terjedő paritás bitek az A-12. táblázat 1. Megjegyzésében megadott egyenlet kielégítésére kerültek kiválasztásra.

14. A 0000 kódolt érték nem megengedett.

15. A 0 futópálya szám megjelölés a helikopter üzemeltetésekre vonatkozik.

A-16. táblázat: Útvonal-pont meghatározó adat-elemek

(lásd a 3.11.4.8.3.2 pontot)

Adattartalom	Felhasznált bitek	Értéktartomány	A legkisebb helyértékű bit

Megszakított megközelítés mutató	6	Lásd az 5.és 6. Megjegyzést.	

MEGJEGYZÉSEK. –

1. A koordináta rendszer kiindulási pontja az MLS alappont. Az X- tengely vízszintes, és a futópálya középvonalát magába foglaló függőleges síkban fekszik, és a pozitív szám a megközelítési vonatkoztatási alappont felé tartó helyeket jelenti. Az Y- tengely vízszintes és az X- tengelyre merőleges, és a pozitív szám a középvonaltól balra lévő helyeket jelenti, az MLS alapponttól a

megközelítési vonatkoztatási alappont felé nézve. A Z- tengely függőleges, és a pozitív szám jelenti az MLS alappont feletti helyet.

2. A kódolás konvenciója a következő:

A legnagyobb helyértékű bit az előjel bit:
0 = pozitív
1 = negatív

A további bitek jelentik az abszolút értékeket.

3. A kódolás konvenciója a következő:
0 = nem
1 = igen

Az "Y koordináta követő" bitjének NULLÁ-ra (nem) állítása azt jelenti, hogy az útvonalpont Y-koordinátája nulla. Ebben az esetben az Y- koordináta adatmezője nem használatos. A "Z koordináta követő" bitjének NULLÁ-ra (nem) állítása vagy azt jelzi, hogy az útvonalpont két-dimenziós vagy azt, hogy két útvonalpont között egy állandó gradiensen fekszik, és ezért van a Z- koordináta kisugározva. Ebben az utolsó két esetben a Z- koordináta adatmezője nem használatos.

4. Ez az adatmező egy előjel nélküli értékkel van kódolva, a -100 m-es eltolt helyzettel. A nulla érték ebben az adatmezőben ennek megfelelően a -100 m-es Z- koordinátát jelenti.

5. Azok az adatmezők, amelyek a következő szakasz / adatmező azonosítót követik, csak bizonyos esetekben kerülnek továbbításra. A következő szakasz / adatmező azonosító kódolása és az azt követő adatmezők felhasználása az A-17. sz. táblázatban került meghatározásra.

6. Az útvonalpont mutató számok egymás utáni számozással a megközelítési oldalszög, vagy hátsó irányszektor adatbázisában lévő valamennyi útvonalpontra kijelölésre kerülnek. Ha egy útvonalpont van az elsődleges futópálya küszöbére úgy kódolva, hogy csak a futópálya küszöb keresztezési magasságot tartalmazza, akkor ez ki van hagyva az útvonalpont mutató sorozatából. A következő útvonalpont mutató adatmező mindig egy, az aktuális útvonalpontnál alacsonyabb mutató számra utal. A megszakított megközelítési mutató adatmező mindig egy, az aktuális útvonalpontnál magasabb mutató számra utal.

</table>

MEGJEGYZÉSEK. –

1. Egy megosztott útvonalpont az az útvonalpont, ami az aktuális eljárásban csak egy útvonalpont mutatóval van azonosítva. Az útvonalpont koordináták kifejezetten egy másik eljárás részeként vannak meghatározva.

2. Ezen az útvonalponton túl, az útirány-vezetési információk arra az egyenes vonalra vannak vonatkoztatva, amely az aktuális útvonalpontból van meghosszabbítva és az útvonalpontba belépő repülési pálya érintője. Egy megszakított megközelítési eljárás esetén ez a vonal metszi az utolsó megközelítési útvonalpontot.

3. A következő szakasz / adatmező azonosító 5. és 7. értékei a csak a megközelítési eljárásokban való felhasználására vannak fenntartva. A megszakított megközelítési és az indulási eljárások megoszthatják azokat a megközelítési útvonalpontokat, amelyek ezeket az értékeket használják fel, szándékosan figyelmen kívül hagyva a futópálya küszöb útvonalpont magasság, a látszólagos oldalszög - futópálya küszöb távolság és a megszakított megközelítés mutató adatmezőt.

B-FÜGGELÉK: A GLOBÁLIS NAVIGÁCIÓS MŰHOLD RENDSZER (GNSS) RÉSZLETES MŰSZAKI ELŐÍRÁSAI

1. MEGHATÁROZÁSOK

GBAS/E. Egy földi-bázisú kiegészítő rendszer /GBAS/, amely elliptikusan polarizált VHF adat-közvetítéssel sugároz.

GBAS/H. Egy földi-bázisú kiegészítő rendszer /GBAS/, amely vízszintesen polarizált VHF adat-közvetítéssel sugároz.

Receiver. Vevő. Egy alrendszer, amely veszi a Globális Navigációs Műhold Rendszer jeleit, és egy, vagy több érzékelőelemet tartalmaz.

Reserved (bit/words/fields). Fenntartott (bitek/szavak/mezők). Bitek, szavak, mezők, melyek nem kerültek kiosztásra, de amelyek egy egyedi Globális Navigációs Műhold Rendszerű alkalmazásra fenn vannak tartva.

Spare (bit/words/fields). Tartalék (bitek/szavak/mezők). Bitek, szavak, mezők, melyek nem kerültek kiosztásra, vagy fenntartásra, és amelyek a jövőbeni kiosztásra rendelkezésre állnak.

Megjegyzés. – Az összes tartalék bit nullára van állítva.

2. ÁLTALÁNOS RÉSZ

Megjegyzés. – A következő műszaki előírások a 3.Fejezet 3.7 pontja alatt leírt rendelkezéseket egészítik ki.

3.1.1 A Nem-légijármű fedélzeti alkotóelemek

3.1.1.1 RÁDIÓFREKVENCIÁS (RF) JELLEMZŐK

3.1.1.1.1 *Vivőhullám fázis zaj*. A modulálatlan vivőhullám fázis zajának spektrális sűrűségének olyannak kell lennie, hogy egy fázisszabályzó hurok 10 Hz-es egy-oldalas zajszűrővel képes legyen a vivőhullám követésére egy 0,1 radiános (1 szigma) pontossággal.

3.1.1.1.2 *Hamis sugárzás*. A sávon belüli hamis sugárzásnak legalább 40 dB-el a modulálatlan L1 vivőhullám alatt kell lenni a kijelölt csatorna sávszélesség teljes egészében.

3.1.1.1.3 *Korrelációs veszteség*. A visszanyert jel teljesítményében a jel moduláció hiányossága és a hullámforma torzítás miatti veszteség nem haladhatja meg az 1 dB-t.

Megjegyzés. – A jel-teljesítmény veszteség az egy 2,046 MHz-es sávszélességben kisugárzott teljesítmény és az egy zajmentes és veszteségmentes 1-chip korrelációs térközű és egy 2,046 MHz-es sávszélességű vevővel visszanyert jel-teljesítmény közötti különbség.

3.1.1.1.4 *A Torzított /durva/ hozzáférési (C/A) kód összeállítása és időzítése*. Az egyes Torzított /durva/ hozzáférési kód mintákat $G_i(t)$ két, a G1 és a $G2_i$ 1023 bites lineáris minta Modulo-2 összegével kell kialakítani. A $G2_i$ sorozatot úgy kell kialakítani, hogy ténylegesen el kell késleltetni a G2 sorozatot egy egészszámú chip-el azért, hogy létrejöjjön a B-1. táblázatban meghatározott 36 egyedi $G_i(t)$ minta egyike. A G1 és G2 sorozatokat egy olyan 10-fokozatú léptető regiszterrel kell összeállítani, amelynek a léptető regiszter bemenetére vonatkoztatva a következő polinom karakterisztikája van:

a) G1: $X^{10} + X^3 + 1$; és

b) G2: $X^{10} + X^9 + X^8 + X^6 + X^3 + X^2 + 1$.

A G1 és G2 sorozatok alaphelyzet beállító címsorozatának ”1111111111”-nek kell lenni. A kód fázis kijelölésnek a B-1. táblázatban bemutatottnak kell lenni. A G1 és G2 tárolókat 1,023 MHz-es ütemmel kell szinkronizálni. A Torzított /durva/ hozzáférési (C/A) kódra vonatkozó időzítési kapcsolatnak a B-1.* ábrán bemutatottnak kell lenni.

* Az összes ábra a Függelék végén került elhelyezésre.

3.1.1.2 *Adat szerkezet*. A navigációs közleményt úgy kell kialakítani, ahogy az a B-2. ábrán bemutatásra került. Az egyes oldalaknak, ahogy azt a B-6. ábra mutatja, egy 1500 bit hosszúságú keret - maximum 5-ig terjedő al-kerettel, amelyek mindegyike 300 bit hosszúságú - alap formátumot kell felhasználni. Az összes szót először a legnagyobb helyértékű bittel (MSB) adva kell továbbítani.

3.1.1.2.1 *Al-keret szerkezet*. Az egyes al-kereteket és/vagy az al-keretek oldalait egy Távolságmérés (TLM) szóval kell kezdeni, amelyet egy Átadás (HOW) szó követ. Az Átadást 8 adatszónak kell követni. Minden egyes keretben minden egyes szónak 6 paritás bitet kell magába foglalni. A TLM szó és a HOW szó formátumát a B-3. és B-4. ábrák mutatják be, külön-külön.

3.1.1.2.2 A Hét vége/kezdete. A Hét végénél/kezdeténél:

a) Az 1-től 5-ig terjedő al-keretek ciklikus lapozását az 1. al-kerettel kell újrakezdeni, függetlenül attól, hogy melyik al-keret volt utoljára a hét végét/kezdetét megelőzően leadva; és

b) A 4. és 5. al-keret 25 oldalának periódikus visszatérését az 1. oldallal kell kezdeni minden egyes al-keretnél, függetlenül attól, hogy melyik al-keret volt utoljára a Hét végét/kezdetét megelőzően leadva. Az összes adat-áttöltésnek, vagy oldal elválasztásnak a keret határainál kell megtörténnie (azaz Modulo 30 másodperc a Hét vége/kezdetéhez viszonyítva).

Megjegyzés. – A 4. és 5. al-keretekben az új adatok továbbítását ezeknek az al-kereteknek bármelyik 25 oldalával lehet megkezdeni.

3.1.1.2.3 *Adat paritás*. Az 1.-től 5.-ig terjedő al-keretek 1.-től 10.-ig terjedő szavainak mindegyike magába kell, hogy foglaljon 6 paritás bitet, mint a legkisebb helyértékű biteket (LSB). Ezenkívül, két nem-információ hordozó bitet kell biztosítani, mint a 2. és 10. szó 23. és 24. bitjét paritás kiszámítási célokra.

3.1.1.2.4 *Távolságmérés (TLM) szó*. Minden egyes TLM szónak 30 bit hosszúságúnak kell lenni, minden egyes 6 másodpercben jelentkezően az adat keretben és minden egyes al-keret első szavának is ennek kell lenni. A Távolságmérés formátuma az kell, hogy legyen, ami a B-3. ábrán bemutatásra kerül. Minden egyes Távolságmérési (TLM) szónak egy bekezdő jelszakasszal, előtaggal kell kezdődni, amit 16 fenntartott bit és 6 paritás bit követ.

3.1.1.2.5 *Átadás szó (HOW).* A HOW-nak 30 bit hosszúnak kell lenni, és minden egyes al-keret/oldal második szava kell, hogy legyen közvetlenül a TLM-et követően. Az Átadásnak (HOW) az adat-keretben minden 6. másodpercben elő kell fordulnia. Az Átadás (HOW) formátumának és tartalmának a B-4. ábrán bemutatottnak kell lenni. A teljes Hét-Idő (TOW) számlálásnak a 29 bit-es Z-számlálás 19 legkisebb helyértékű bitjéből kell állni (3.1.1.2.6). Az Átadásnak (HOW) a Hét-Idő (TOW) számlálás 17 legnagyobb helyértékű bitjével kell kezdődni. A 17. bit meg kell, hogy feleljen a Hét-Idő (TOW) számlálásnak az 1,5 másodperces korszaknál /epoch/, ami a következő ezt követő al-keret indulásánál (felfutó él) fordul elő.

3.1.1.2.5.1 *A 18. bit*. A 001 konfigurációs kóddal kijelölt műholdon a 18. bitnek egy "riasztás" kijelzésnek kell lenni. Amikor ez a kijelzés 'megjelenik' (a 18. bit "1" lesz), akkor ezen azt kell a felhasználó részére jelezni, hogy a műhold felhasználói távolság pontossága (URA) lehet, hogy rosszabb annál, mint ami az 1. al-keretben jelzett volt, és a műhold felhasználása a felhasználók kockázatát képezi.

B-1. táblázat: Kód fázis kijelölések

Műhold azonosító szám	GPS Ál-véletlen zaj (PRN) jel	G2 késleltetés (chip-ek)	Az első 10 chip nyolcas számrendszerű*
1	1	5	1440
2	2	6	1620
3	3	7	1710
4	4	8	1744
5	5	17	1133

***	33	863	1745
***	34**	950	1713
***	35	947	1134
***	36	948	1456
***	37**	950	1713

* A Torzított /durva/ hozzáférési (C/A) kód első 10 chipjének az oktális írásmódja az, ahogy az ebben a számoszlopban bemutatásra került, az első számjegy egy ”1”-et képvisel az első chipre és az utolsó három számjegy a fennmaradó 9 chip hagyományos nyolcas számrendszerű feltűntetése (például, a Torzított /durva/ hozzáférési kód első tíz chipje az ál-véletlen zaj (PRN) jel 1.összeállítására: 1100 100000).
** A Torzított /durva/ hozzáférési (C/A) kódok 34-es és 37-es kódja közös.
*** Az ál-véletlen zaj /PRN/ jelnek a 33-tól a 37-ig terjedő összeállításai egyéb felhasználásokra van fenntartva (például: földi adók).

3.1.1.2.5.2 *A 19. bit.* A 19. bitet fenn kell tartani.

3.1.1.2.5.3 *A 20., 21. és 22. bitek*. Az Átadás (HOW) 20., 21. és 22. bitjének kell azonosítania azt az al-keretet, amelyben ez az adott Átadás (HOW) a második szó. Az Azonosító (ID) kódot az alábbiak szerint kell meghatározni:

Azonosító (ID)	Kód
1	001
2	010
3	011
4	100
5	101

3.1.1.2.6 *A Műhold Z-számlálása*. Minden egyes műholdnak önmagán belül vezérelnie kell egy 1,5-másodperces 'korszakot' /epoch/, hogy magába foglaljon egy megfelelő egységet az idő pontos számlálásához és közléséhez. Az ily módon meghatározott időt úgy nevezzük, hogy ez a Z-számlálás. A Z-számlálást a felhasználó részére egy 29 bites bináris számként kell biztosítani, amely a következőknek megfelelően két részből áll.

3.1.1.2.6.1 *Hét-Idő (TOW) számlálás*. A Z-számlálás 19 legkisebb helyértékű bitjével megjelenített bináris számot úgy kell besorolni, hogy az a Hét-Idő számlálás és úgy kell meghatározni, hogy ez egyenlő azon 1,5 másodperces korszakok számával, ami a megelőző hétről történt áttérés óta bekövetkezett. A számlálásnak rövid ciklusú léptetésűnek kell lenni úgy, hogy a Hét-Idő /TOW/ számlálás tartománya a 0-tól a 403 199-ig egy 1,5 másodperces korszak legyen (egy héttel egyenlő), és minden egyes hét végén vissza kell állítani nullára. A Hét-Idő számlálások nulla állapotának az 1,5 másodperces korszaknak kell lenni, avval, ami azonos a jelenlegi hét kezdetével. A Hét-Idő /TOW/ számlálás levágott változatát, ami a 17 legnagyobb helyértékű bitjéből áll, kell, hogy magába foglalja az Átadás /HOW/ az L1 lefelé irányuló adatfolyamban. A tényleges Hét-Idő /TOW/ számlálás és annak levágott Átadás /HOW/ változata közötti összefüggésnek a B-5. ábrán bemutatottnak kell lenni.

Megjegyzés. – A fent említett 'korszak' (megközelítőleg) a Szombat éjszaka/Vasárnap reggel éjfélnél jelentkezik, ahol az idő 0000 óraként van meghatározva az Egyeztetett Világidő /UTC/ szerint, ami névlegesen a Greenwich délkörre van vonatkoztatva.

3.1.1.2.6.2 Hét számlálás. A Z-számlálás 10 legnagyobb helyértékű bitjének kell a jelenlegi Globális Helymeghatározó Rendszer /GPS/ hétjére (Modulo 1024) kiosztott sorrendi szám bináris adat feltűntetésének lenni. Ennek a számlásnak a tartománya 0-tól 1023-ig terjed. A nulla állapota az a hét kell, hogy legyen, amely a (megközelítőleges) Egyeztetett Világidő nulla időpontjában jelentkező 1,5 másodperces korszakkal kezdődik. A Globális Helymeghatározó Rendszer /GPS/ hét 1023 számának a lejárásakor a GPS hét számnak nullára kell "átfordulni". A megelőző 1024 heteket a GPS idejéből egy naptári dátumra a felhasználónak kell átalakítva visszavezetni.

3.1.1.3 ADAT TARTALOM

3.1.1.3.1 *1. Al-keret – műhold óra és működési állapot*. Az 1. al-keret 3.-tól 10.-ig terjedő szavainak tartalma kell, hogy magába foglalja az idő paramétereket és az egyéb adatokat, ahogy az a B-2. táblázatban feltűntetésre került. Az egy adatállományban lévő paramétereknek érvényesnek kell lenni azon időtartam alatt, amíg leadásra kerülnek, és érvényes kell, hogy maradjon a leadás ideje után addig a kiegészítő időtartamig, amíg a következő adatállomány továbbítása megkezdődik.

3.1.1.3.1.1 *Hét számozás*. A 3. szó 10 legnagyobb helyértékű bitjének kell magába foglalnia a 29 bites Z-számlálás 10 legnagyobb helyértékű bitjét és kell képviselnie a Globális Helymeghatározó Rendszer /GPS/ érvényes hetének számát az adatátviteli időközének kezdetével az összes nullával jelezve azt, hogy a hét "nulla". A GPS hét számozását minden egyes hét korszak végénél/kezdeténél kell megemelni.

3.1.1.3.1.2 *Felhasználói Távolság Pontosság (URA)*. A 3. szó 13-tól 16-ig terjedő bitjeinek kell biztosítani az előre jelzett műhold Felhasználói Távolság Pontosságot úgy, ahogy az a B-3. táblázatban bemutatásra került.

1. Megjegyzés. – A Felhasználói Távolság Pontosság (URA) nem foglalja magába az egy-frekvenciás ionoszférikus késési modell pontatlansága miatti hiba becsléseket.

2. Megjegyzés. – Az URA a látható idő /óra/ és a műhold-állási előrejelzés pontosságának a vonatkozó statisztikai jelzése arra a távolság-meghatározási pontosságra, ami egy meghatározott műholdról az addigi adatsorozatra alapozva elérhető.

B-2. táblázat: Az 1. al-keret paraméterei

Paraméter	A bitek száma**	Osztás tényező (LSB)	Tényleges tartomány***	Mértékegység
A hét száma	10	1		hetek
Műhold pontosság	4			
Műhold működési állapot	6	1		diszkrét
T_{GD}	8*	2^{-31}		másodperc
IODC	10			
t_{oc}	16	2^{4}	604 784	másodperc
a_{f2}	8*	2^{-55}		másodperc/mp^2
a_{f1}	16*	2^{-43}		másodperc/mp
a_{f0}	22*	2^{-31}		másodperc

* Az így jelzett paramétereknek két komplemenses összetevője van, a Legnagyobb helyértékű bitet /MSB/ elfoglaló (+ vagy -) előjel bittel.
** Lásd a B-6. ábrán a teljes bit kiosztást.
*** Ha ebben az oszlopban nincs másképpen jelezve, a tényleges tartomány a maximális tartomány.
LSB = A legkisebb helyértékű bit

B-3. táblázat: Felhasználói távolság pontosság

Felhasználói távolság pontosság (URA)	Pontosság
0	2 m
1	2.8 m
2	4 m
3	5.7 m
4	8 m
5	11.3 m
6	16 m
7	32 m
8	64 m
9	128 m
10	256 m
11	512 m
12	1024 m
13	2048 m
14	4096 m
15	ne használják

3.1.1.3.1.3 *Működési állapot*. A 3. szó 17-22 bitjeinek kell tartalmaznia a kisugárzó műhold 6-bites működési állapotának jelzését. A legnagyobb helyértékű bit (MSB) jelezze ki a navigációs adat működési állapotának összegzését, ahol:

a) 0 = az összes navigációs adat érvényes; és

b) 1 = a navigációs adat egy része nem érvényes.

Az 5 legkisebb helyértékű bitnek (LSB-k) kell jeleznie a jel összetevők működési állapotát a 3.1.1.3.3.4 pontban leírtakkal összhangban. A működési állapot jelzést az egyes műholdak alkalmasságához viszonyítva kell jelezni, ahogy az a 3.1.1.3.3.5 pontban leírt konfigurációs kódnál kijelölésre került. Akármelyik műholdat, amelynek nincs meg egy bizonyos alkalmassága, "működőképes állapotú"-nak kell jelezni akkor, ha ennek az alkalmasságnak a hiánya a műhold tervezésétől elválaszthatatlan, vagy egy olyan módban van konfigurálva, amely a vevő szempontjából szabályos, és nincs szüksége erre a 'képességre'. A kiegészítő működési állapot /health/ adatokat a 4. és 5. al-keretben kell megadni.

Megjegyzés. – Az 1. al-keretben megadott adatok eltérhetnek azoktól, amelyek más műholdakra a 4. és/vagy 5. al-keretben bemutatásra kerültek, mivel az utóbbiak eltérő időben kerültek felfrissítésre.

3.1.1.3.1.4 *Adatkibocsátás, óra (IODC)*. Az 1. al-keret 3. szava 23. és 24. bitjeinek kell magukba foglalniuk az Adatkibocsátás, óra (IODC) 10-bitjéből a 2 legnagyobb helyértékű bitjét /MSB/. Az 1. al-keret 8. szavának 1.-től 8.-ig terjedő bitjeinek kell tartalmazniuk az IODC 8 legkisebb helyértékű bitjét. Az IODC-nek jeleznie kell az adatkészlet kibocsátási számát.
Az Adatkibocsátás, óra (IODC)-nek különböznie kell minden olyan értéktől, amit a műhold a megelőző 7 nap során leadott.

Megjegyzés. – Az Adatkibocsátás, óra (IODC) és az Adatkibocsátás, Efemerisz /keringési pálya/ (IODE) szakkifejezések közötti összefüggés a 3.1.1.3.2.2 pontban került meghatározásra.

3.1.1.3.1.5 *Számított csoportkésés különbözet*. A 7. szó 17.-től 24.-ig terjedő bitjeinek kell magukba foglalni a T_{GD} /Csoportkésési idő/ helyesbítési tényezőt, a műholdak csoportkésési különbözete hatásának beszámításához.

Megjegyzés. – A T_{GD} /Csoportkésési idő/ nem foglal magába semmilyen C/A-t [durva/ torzított hozzáférés]a P(Y) /precíziós/ kódban a relatív csoportkésési hibára vonatkozóan.

3.1.1.3.1.6 *Műhold óra helyesbítési paraméterek*. A 8. szó 9.-től 24.-ig terjedő bitjeinek, a 9. szó 1.-től 24.-ig terjedő bitjeinek és a 10. szó 1.-től 22.-ig terjedő bitjeinek kell tartalmazniuk azokat a paramétereket, amelyek a felhasználó részére a látszólagos műhold óra helyesbítésekhez (t_{oc}, a_{f2}, a_{f1} és a_{f0}) szükségesek.

3.1.1.3.1.7 *Fenntartott adatmezők*. A fenntartott adatmezőknek azoknak kell lenni, amelyeket a B-4. táblázat megad. Az összes fenntartott adatmezőnek a megfelelő szavakon belül érvényes paritással kell rendelkezni.

3.1.1.3.2 *2. és 3. Al-keretek – műhold efemerisz /keringési pálya/ adatok*. A 2. és 3. al-keretnek kell magába foglalnia az adattovábbító műhold efemerisz ábrázolását.

3.1.1.3.2.1 *Efemerisz paraméterek*. Az efemerisz /keringési pálya/ paramétereknek a B-5. táblázatban megadottaknak kell lenni. A 2. és 3. al-keret egyes paramétereinek, a bitek számának, a legkisebb helyértékű bitek osztás tényezőjének, a tartományának és mértékegységeinek a B-6. táblázatban meghatározottaknak kell lenni.

3.1.1.3.2.2 *Adatkibocsátás, efemerisz (IODE)*. Az Adatkibocsátás, efemerisz (IODE)-nek annak a 8 bites számnak kell lenni, ami ugyanazon adatállomány 10 bites Adatkibocsátás, óra (IODC)-nak a 8 legkisebb helyértékű bitjeivel egyenlő. Az Adatkibocsátás, efemerisz (IODE)-t mind a 2., mind a 3. al-keretben biztosítani kell az 1. al-keretben lévő Adatkibocsátás, óra (IODC) tényezőnek a 8 legkisebb helyértékű bitjével történő összehasonlítás céljából. Amikor ez a három tényező nem egyezik az adatállomány levágásának eredményeként, akkor új adatokat kell összegyűjteni. A leadott Adatkibocsátás, efemerisz (IODE)-nek eltérőnek kell lenni a műhold által a megelőző 6 órában továbbított bármilyen értéktől (1. Megjegyzés). A 2. és 3. al-keret adataiban történt bármilyen módosulást el kell végezni egy változtatással egyetértésben mindkét Adatkibocsátás, efemerisz (IODE) szóban. Az új adatállomány változtatásnak csak az óra határvonalaknál kell megtörténni, kivéve egy új adatáttöltés első adatállományát. Kiegészítésképpen a t_{oe} értéknek, amelyet a műhold egy adatáttöltés után továbbít, legalább az első adatállománya eltérő kell, hogy legyen attól, mint amit a változást megelőzően továbbított (2. Megjegyzés).

B-4. táblázat: 1. Al-keret fenntartott adatmezők

Szó	Bit
3	11 - 12
4	1 - 24
5	1 - 24
6	1 - 24
7	1 - 16

B-5. táblázat: Efemerisz adatok

M_0	Közepes anomália a referencia időnél
Δn	Közepes szögsebesség eltérés a számított értéktől
e	Excentricitás
$\sqrt{A}$	A fél nagytengely négyzetgyöke
$OMEGA_0$	A műhold pályasík felszálló csomó/pont/jának földrajzi hosszúsága a hetenkénti korszaknál
i_0	Inklinációs /pályaelhajlási/ szög a referencia időnél
ω	A földközel argumentuma
OMEGADOT	A rektaszcenzió /egyenes emelkedés/ mértéke
iDOT	A pályaelhajlás szögeinek mértéke
C_{uc}	A szélességi fok koszinusz harmonikus helyesbítési tényezőjének amplitúdója
C_{us}	A szélességi fok szinusz harmonikus helyesbítési tényezőjének amplitúdója
C_{rc}	A körpálya sugara koszinusz harmonikus helyesbítési tényezőjének amplitúdója
C_{rs}	A körpálya sugara szinusz harmonikus helyesbítési tényezőjének amplitúdója
C_{ic}	A pályaelhajlás szöge koszinusz harmonikus helyesbítési tényezőjének amplitúdója
C_{is}	A pályaelhajlás szöge szinusz harmonikus helyesbítési tényezőjének amplitúdója
t_{oe}	Referencia idő, efemerisz /keringési pálya/
IODE	Adatkibocsátás, efemerisz /keringési pálya/

B-6. táblázat: Efemerisz paraméterek

Paraméter	A bitek száma**	Osztás tényező (LSB)	Tényleges tartomány***	Mértékegység
IODE	8			
C_{IS}	16*	2^{-5}		méter
Δn	16*	2^{-43}		félkör/másodperc
M_0	32*	2^{-31}		félkör
C_{UC}	16*	2^{-29}		radián
e	32	2^{-33}	0,03	dimenzió nélküli
C_{US}	16*	2^{-29}		radián
$\sqrt{A}$	32	2^{-19}		$\text{méter}^{1/2}$
t_{oe}	16	2^4	604 784	másodperc

ω	32*	2^{-31}		félkör
OMEGADOT	24*	2^{-43}		félkör/másodperc
iDOT	14*	2^{-43}		félkör/másodperc

* Az így jelzett paramétereknek két komplemenses összetevője van, a Legnagyobb helyértékű bitet /MSB/ elfoglaló (+ vagy -) előjel bittel.

** Lásd a B-6. ábrán a teljes bit kiosztást az al-keretben.

*** Ha ebben az oszlopban nincs másképpen jelezve, a tényleges tartomány az a maximális tartomány, ami a megadott bit kijelöléssel és osztás tényezővel elérhető.

LSB = A legkisebb helyértékű bit

1. Megjegyzés. – Az Adatkibocsátás, efemerisz/Adatkibocsátás, óra (IODE/IODC) tényezők adják a vevő részére azt az eszközt, amellyel érzékeli az efemerisz/óra 'ábrázoló' paraméterének bármilyen változását.

2. Megjegyzés. – Az első adatállomány megváltoztatható (3.1.1.2.2) az óra során bármikor, és ennek megfelelően a műhold 1 órán belül is leadhatja.

3.1.1.3.2.3 *Fenntartott adatmezők*. A 2. al-keret 10. szaván belül a 17.-től a 22.-i terjedő biteket fenn kell tartani. A fenntartott adatmezőknek az érvényes paritást kell támogatniuk a megfelelő szavakon belül.

3.1.1.3.3 *4. és 5. al-keret – kiegészítő adatok*. Mindkét, a 4. és 5. al-keretnek 25-ször szub-kommutáltnak kell lenni. A "fenntartott" oldalak és a kifejezett ismétlések lehetséges kivételével az egyes oldalaknak különböző adatokat kell a 3.-tól a 10.-ig terjedő szavaikban magukba foglalni. A 4. al-keret oldalainak 6 különböző formátumot kell felhasználniuk, és az 5. al-keret oldalainak két különböző formátumot kell használni, ahogy azt a B-6. ábra bemutatja.

A 4. al-keret oldalainak a következőknek kell lenni:

a) A 2., 3., 4., 5., 7., 8., 9. és 10. oldalak: naptár adatok a 25.-től a 32.-ig terjedő műholdakra, külön-külön. Amikor a 25. oldal 6 bites működési állapot szava 6db "egyesre" van állítva (3.1.1.3.3.4), akkor az oldal műhold azonosítójának /ID/ értéke nem lesz a 25.-től a 32.-ig terjedő tartományban;

Megjegyzés. – Ezeket az oldalakat ki lehet jelölni egyéb funkciókra. Az egyes oldalak formátumát és tartalmát a vonatkozó oldalnak a műhold azonosítója /ID/ jelöli ki.

b) 17. oldal: speciális közlemények;

c) 18. oldal: ionoszféra és Egyeztetett Világidő /UTC/ adatok;

d) 25. oldal: műhold konfiguráció a 32 műholdra; és

e) 1., 6., 11., 12., 13., 14., 15., 16., 19., 20., 21., 22., 23. és 24. oldal: fenntartott oldalak.

Az 5. al-keret oldalai a következők kell, hogy legyenek:

a) Az 1.-től a 24.-ig terjedő oldalak: naptár adatok az 1.-től a 24.-ig terjedő műholdakra; és

b) 25. oldal: műhold működési állapot adatok az 1.-től a 24.-ig terjedő műholdakra, a naptár referencia ideje és a naptár referencia hét száma.

3.1.1.3.3.1 *Adat Azonosító /ID/.* A 3. szó két legnagyobb helyértékű bitjének /MSB/ minden egyes oldalon magába kell foglalnia azt az Adat azonosítót /ID/, amely meghatározza a felhasználható Globális Helymeghatározó Rendszer /GPS/ navigációs adatszerkezetét. Az Adat azonosítónak olyannak kell lenni, ahogy azt a B-7. táblázat bemutatja, az alábbiakkal összhangban:

a) azoknál az oldalaknál, amelyek úgy vannak kijelölve, hogy egy meghatározott műhold naptár adatait foglalják magukba, az Adat azonosítónak kell meghatároznia azt az adat szerkezetet, amelyet az a műhold használ fel, amelynek a naptár adatait ez az oldal foglalja magába;

b) az összes egyéb oldalra az Adat azonosítónak kell jelezni az adattovábbító műhold adat szerkezetét; és

c) az "1" Adat azonosítót (a bináris állapot 00-val jelezve) nem lehet felhasználni.

3.1.1.3.3.2 *Műhold azonosító*. A Műhold azonosítót minden egyes oldal 3. szavának a 3.-tól a 8.-ig terjedő bitjeivel kell biztosítani. A Műhold azonosítót kétféle módon kell felhasználni:

a) azoknál az oldalaknál, amelyek egy adott műhold naptár adatait tartalmazzák, a Műhold azonosítónak ugyanazon számúnak kell lenni, mint ami annak a műholdnak az ál-véletlen zaj /PRN/ kód fázisára ki van jelölve a B-1. táblázatban megadottakkal összhangban; és

b) az összes egyéb oldalaknál a Műhold azonosító a B-7. táblázatban megadottakkal összhangban van kijelölve "oldal azonosítóként" kell, hogy szolgáljon. Az 1.-től a 32.-ig terjedő azonosítókat azokra az oldalakra kell kijelölni, amelyek a meghatározott műholdak naptár adatait foglalják magukba (az 5. al-keret 1.-től 24.-ig terjedő oldalai és a 4. al-keret 2.-től 5.-ig terjedő, valamint 7.-től 10.-ig terjedő oldalai). A "0" ID-t (binárisan mindenhol nullák) annak jelzésére kell kiosztani, hogy az egy látszólagos /dummy/ műhold, míg az 51.-től a 63.-ig terjedő azonosítókat az olyan oldalakra kell felhasználni, amelyek más naptári adatokat tartalmaznak egy meghatározott műholdra (1. és 2. Megjegyzés).

1. Megjegyzés. – Meghatározott azonosítók vannak fenntartva a 4. és 5. al-keret egyes oldalaira, azonban a 4. al-keret 2., 3., 4., 5., 7., 8., 9. és 10. oldalainak Műhold azonosítói az egyes oldalakra változtathatók, hogy annak az oldalnak a váltakozó tartalmára utaljanak.

2. Megjegyzés. – A fennmaradó ID-k (a 33.-tól az 50.-ig terjedően) nincsenek kijelölve.

B-7. táblázat: Adat azonosítók és Műhold azonosítók a 4. és 5. al-keretben.

	4. Al-keret		5. Alkeret	
Oldal	Adat azonosító	Műhold azonosító*	Adat azonosító	Műhold azonosító*

25	***	63	***	51

* A “0” a “látszólagos” műholdat jelzi. Amikor a “0”-t használják egy látszólagos műhold jelzésére, akkor az adattovábbító műhold Adat azonosítója használatos.

** Annak a műholdnak az Adat azonosítója, amelynek a Műhold azonosítója jelenik meg azon az oldalon.
*** Az adattovábbító műhold Adat azonosítója.

**** A 4. al-keret 2., 3., 4., 5., 7., 8., 9. és 10. oldalai magukba foglalhatnak naptár adatokat a 25.-től a 32.-ig terjedő műholdakra, külön-külön, vagy egyéb funkciókra vonatkozó adatokat, ahogy az a különböző Műhold azonosítókkal a bemutatott értékekből megállapítható.

***** A Műhold azonosító változtatható.

3.1.1.3.3.3 *Naptár*. Az 5. al-keret 1.-től 24.-ig terjedő oldalainak, valamint a 4. al-keret 2.-től 5.-ig és a 7.-től 10.-ig terjedő oldalainak kell magukba foglalniuk a naptár adatokat és a műhold működési állapot /health/ szót (3.1.1.3.3.4) mind a 32 műholdra. A naptár adatoknak az óra és az efemerisz paraméterek egy csökkentett-pontosságú rész-halmazának kell lenni. Az adatnak el kell foglalnia az egyes oldalak 3.-tól 10.-ig terjedő szavainak összes bitjét, kivéve a 3. szó 8 legnagyobb helyértékű bitjeit (Adat azonosító és Műhold azonosító), az 5. szónak a 17.-től a 24.-ig terjedő bitjeit (műhold működési állapot /satellite health/) és a paritásra szánt 50 bitet. A bitek számának, az osztási tényezőnek (legkisebb helyértékű bit), a távolságnak és a naptár paraméterek egységeinek azoknak kell lenni, amit a B-8. táblázat bemutat. Az egyes látszólagos /dummy/ műholdak naptár közleményeinek váltakozó “egyeseket” és “nullákat” kell érvényes paritással magukba foglalni.

3.1.1.3.3.3.1 *Naptár referencia idő*. A naptár referencia időnek – a t_{oa}-nak – a 2^{12} másodperc többszörösének kell lenni az ennek a naptár adatállománynak az első érvényes továbbítási ideje utáni körülbelül 70 órával bekövetkezően. A naptárt megfelelő gyakorisággal kell felfrissíteni annak biztosításához, hogy a Globális Helymeghatározó Rendszer /GPS/ ideje
(t) a t_{oa}-tól /referencia idő/ az adattovábbítási időtartamban 3,5 napnál kevesebbel legyen eltérő. A naptár paramétereket legalább 6-naponként egyszer fel kell frissíteni a szabályos üzemeltetés során.

3.1.1.3.3.3.2 *Naptár idő paraméterek*. A naptár idő paramétereknek egy 11 bites állandó tagból (a_{f0}) és egy 11 bites elsőfokú tagból (a_{f1}) kell állniuk.

3.1.1.3.3.3.3 *Naptár referencia hét*. Az 5. al-keret 25. oldalán lévő 3. szó 17.-től 24.-ig terjedő bitjeinek kell jelezni annak a hétnek a számát (WN_a), amelyre a naptár referencia ideje (t_{oa}) vonatkoztatva van. A Hét száma /WN_a/ kifejezésnek a teljes hét számának a 8 legkisebb helyértékű bitjéből kell állnia. Az 5. al-keret 25. oldala 3. szavának 9.-től 16.-ig terjedő bitjeinek kell magába foglalnia a t_{oa} /naptár referencia idő/ értéket, ami erre a WN_a-ra /a Hét száma/ van vonatkoztatva.

3.1.1.3.3.4 *Működési állapot /health/ összefoglalása*. A 4. és 5. al-keretnek kell tartalmaznia a műhold működési állapot adatainak két típusát:

a) a 32 oldal mindegyikének, amely tartalmazza az óra/naptár adatokat, biztosítania kell egy 8 bites műhold működési állapot szót arra a műholdra vonatkozóan, amelynek a naptár adatait az a műhold továbbítja; és

b) a 4. és 5. al-keret 25. oldalának közösen kell tartalmazni a 6 bites működési állapot adatot a 32 műholdra.

3.1.1.3.3.4.1 A 8-bites működési állapot szavaknak az 5. szó 17.-től 24.-ig terjedő bitjeit kell elfoglalniuk azon a 32 oldalon, amely a naptár adatokat tartalmazza az egyes műholdakra. A 6-bites működési állapot szavaknak az 5. al-keret 25. oldalán lévő 4.-től 9.-ig terjedő szavak 24 legnagyobb helyértékű bitjét és a 4. al-keret 25. oldalán lévő 8. szó 19.-től 24.-ig terjedő bitjeit, a 9. szó 24 legnagyobb helyértékű bitjeit és a 10. szó 18 legnagyobb helyértékű bitjeit kell elfoglalniuk.

B-8. táblázat: Naptár paraméterek

Paraméter	A bitek száma**	Osztás tényező (LSB)	Tényleges tartomány***	Mértékegység
e	16	2^{-21}		dimenzió nélküli
t_{oa}	8	2^{12}	602 112	másodperc
δ_i****	16*	2^{-19}		félkör
OMEGADOT	16*	2^{-38}		félkör/másodperc
$\sqrt{A}$	24*	2^{-11}		méter$^{1/2}$
$OMEGA_0$	24*	2^{-23}		félkör
ω	24*	2^{-23}		félkör
M_0	24*	2^{-23}		félkör
a_{f0}	11*	2^{-20}		másodperc
a_{f1}	11*	2^{-38}		másodperc/mp

* Az így jelzett paramétereknek két komplemenses összetevője van, a Legnagyobb helyértékű bitet /MSB/ elfoglaló (+ vagy -) előjel bittel.

** Lásd a B-6. ábrán a teljes bit kiosztást az al-keretben.

*** Ha ebben az oszlopban nincs másképpen jelezve, a tényleges tartomány az a maximális tartomány, ami a megadott bit kijelöléssel és osztás tényezővel elérhető.

**** Az i_0-ra vonatkoztatva = 0,30 félkör.

LSB = A legkisebb helyértékű bit

3.1.1.3.3.4.2 A 8-bites működési állapot szavak 3 legnagyobb helyértékű bitjének kell jeleznie a navigációs adatok állapotot a B-9. táblázatban megadott kódnak megfelelően. A 6-bites szavaknak a navigációs adatok állapotának egy 1-bites összegzését kell megadni a legnagyobb helyértékű bitek /MSB/ helyzetében a 3.1.1.3.1.3.pontban leírtakkal összhangban. Mind a 8-bites, mind a 6-bites működési állapot szavak 5 legkisebb helyértékű bitjének /LSB/ kell a műhold jel összetevőinek állapotát biztosítani a B-10. táblázatban megadott kódnak megfelelően.

B-9. táblázat: A navigációs adatok működési állapotának jelzése

A bitek helyzete az oldalon			Jelzés
137	138	139	
0	0	0	AZ ÖSSZES ADAT RENDBEN VAN.
0	0	1	PARITÁS HIBA – néhány, vagy az összes paritás rossz
0	1	0	TÁVOLSÁGMÉRÉS/ÁTADÁS /TLM/HOW/ FORMÁTUM PROBLÉMA – valamilyen eltérés a szabvány formátumtól (pl. a bevezető jelszakasz nincs a helyén és/vagy pontatlan), kivéve a pontatlan Z-számlálást, ahogy az ÁTADÁSban közölve van.
0	1	1	A Z-SZÁMLÁLÁS AZ ÁTADÁSban /HOW/ ROSSZ, valami probléma van a Z-számlálás értékével, nem tükrözi a tényleges kód fázist.
1	0	0	1., 2., 3. AL-KERET – egy, vagy több elem a 3.-tól a 10.-ig terjedő szavakban, egy, vagy több al-keret rossz.
1	0	1	4., 5. AL-KERET – egy, vagy több elem a 3.-tól a 10.-ig terjedő szavakban, egy, vagy több al-keret rossz.
1	1	0	AZ ÖSSZES ÁTTÖLTÖTT ADAT ROSSZ – egy, vagy több elem a 3.-tól a 10.-ig terjedő szavakban, egy (vagy több) al-keret rossz
1	1	1	AZ ÖSSZES ADAT ROSSZ – a Távolságmérés /TLM/ szó és/vagy az Átadás /HOW/ és egy, vagy több elem bármelyik (vagy több) al-keretben rossz.

B-10. táblázat: A működési állapot műhold jel összetevők kódjai

MSB				LSB	Jelzés
0	0	0	0	0	AZ ÖSSZES JEL RENDBEN VAN.
1	1	1	0	0	A MŰHOLD IDEIGLENESEN NEM MŰKÖDIK – ne használják ezt a műholdat a jelenlegi átmenet ideje alatt.______
1	1	1	0	1	A MŰHOLD IDEIGLENESEN KI VAN KAPCSOLVA - körültekintéssel használják. ______
1	1	1	1	0	TARTALÉK
1	1	1	1	1	EGYNÉL TÖBB KOMBINÁCIÓRA LENNE SZÜKSÉG A RENDELLENESSÉGEK LEÍRÁSÁRA, KIVÉVE AZOKAT, AMELYEKET CSAK ______VEL JELÖLTEK.
Minden egyéb kombináció					A MŰHOLD KÓD MODULÁCIÓS ÉS/VAGY JEL-TELJESÍTMÉNY SZINT ADATTOVÁBBÍTÁSI PROBLÉMÁKAT ÉSZLEL. A felhasználó kihagyó követési problémákat észlelhet, ha a műholdat befogja.

MSB = legnagyobb helyértékű bit
LSB = legkisebb helyértékű bit

3.1.1.3.3.4.3 Különleges jelentést kell kiadni a 4. és 5. al-keret 25. oldalán lévő 6-bites működési állapot szavak 6db "egyes" kombinációjának; ennek azt kell jelezni, hogy "a műhold, melynek az azonosítója /ID/ nem elérhető, és lehet, hogy nincs adat arra a műholdra vonatkozóan a 4., vagy 5. al-keret oldalán, ami arra van kijelölve, hogy szabályszerűen annak a műholdnak a naptár adatait tartalmazza".

Megjegyzés. – Ez a különleges jelentés csak a 4. és 5. al-keret 25. oldalára vonatkozik. Lehet ott egy másik műholdra vonatkozó adat, a fentiekben említett naptár oldalon, úgy, ahogy az a 3.1.3.3.3.3 pontban meghatározásra került.

3.1.1.3.3.4.4. A működési állapot jelzést az egyes műholdak képességeire vonatkoztatva kell biztosítani úgy, ahogy azt a 3.1.1.3.3.5 pontban a konfigurációs kód kijelöli. Ennek megfelelően bármelyik műholdat, amelynek nincs meg egy bizonyos képessége, "jó működési állapotú"-nak kell jelezni akkor, ha ennek a képességnek a hiánya a műhold tervezéséhez hozzátartozik, vagy ha egy olyan módban van konfigurálva, ami a vevő nézőpontjából szabályos és nem igényli azt a képességet. Az előre látható működési állapot adatot az adatáttöltés idején kell felfrissíteni.

1. Megjegyzés. – A leadott működési állapot adatok lehet, hogy nem egyeznek meg az adattovábbító műhold, vagy a műhold rendszerben lévő másik műholdak tényleges működési állapotával.

2. Megjegyzés. – Az 1., 4. és 5. al-keretben megadott, a másik műholdakra vonatkozó adatok eltérőek lehetnek attól, mint amit a 4. és/vagy 5. al-keretek mutatnak, mivel az utóbbiak más időpontban felújított adatok lehetnek.

3.1.1.3.3.5 *Műhold konfiguráció összegzés*. A 4. al-keret 25. oldalának kell tartalmaznia azt a 4-bit hosszúságú tagot a 32 műhold mindegyikére, amely megmutatja az egyes műholdak konfigurációs kódját. Ezeknek a 4-bites tagoknak a 4. al-keret 25. oldalán lévő 3. szó 9.-től 24.-ig terjedő bitjeit, a 4.-től a 7.-ig terjedő szavak 24 legnagyobb helyértékű bitjeit, és a 8. szó 16 legnagyobb helyértékű bitjét kell elfoglalniuk. Az egyes mezők első legnagyobb helyértékű bitjét fenn kell tartani. A 3 legkisebb helyértékű bitnek kell jelezniük az egyes műholdak konfigurációját a következő kód felhasználásával:

Kód	Műhold konfiguráció
001	Block II. műhold

3.1.1.3.3.6 *Egyeztetett Világidő /UTC/ paraméterek*. A 4. al-keret 18. oldalának kell magába foglalnia:

a) azokat a paramétereket, amelyek a Globális Helymeghatározó Rendszer /GPS/ idejének az Egyeztetett Világidő /UTC/ időhöz való vonatkoztatáshoz szükségesek; és

b) értesítést a felhasználónak a beütemezett jövőre, vagy múltra (a navigációs közlemény adatáttöltésére vonatkozóan) a szökő másodpercek (t_{LSF}) miatti delta idő értékével, a hét számával (WN_{LSF}) és a nap számával (DN) együtt a végén, hogy a szökő másodpercek melyike válik érvényessé. Az "Első nap"-nak a Hét vége/kezdetéhez viszonyított első napnak kell lennie, és a Hét száma /WN_{LSF}/ értékének a teljes hét szám 8 legkisebb helyértékű bitjéből kell állni. A nem-megcsonkított WN és a WN_{LSF} értéke közötti különbség abszolút értéke nem haladhatja meg a 127-et.
Megjegyzés. – A felhasználó ennek a paraméternek a megcsonkított jellemzőjű jellegére számít, valamint a WN, WN_t és WN_{LSF} megcsonkítására a teljes hét számának átfordulása miatt (3.1.1.2.6.2).

3.1.1.3.3.6.1 A 4. al-keret 18. oldalán a 6.-tól a 9.-ig terjedő szavak 24 legnagyobb helyértékű bitjének és a 10. szó 8 legnagyobb helyértékű bitjének kell magába foglalni az Egyeztetett Világidőnek /UTC/ a Globális Helymeghatározó Rendszer /GPS/ idejének összeegyeztetésére szolgáló paramétereket. A bit hosszak, az osztási tényezők, a távolságok és egységek ezekhez a paraméterekhez a B-11. táblázatban vannak meghatározva.

3.1.1.3.3.7 *Ionoszférikus paraméterek.* Az ionoszférikus paraméterek azok, amelyek hozzájárulnak a Globális Helymeghatározó Rendszer /GPS/ Szabvány Helymeghatározási Szolgáltatását /SPS/ felhasználó részére ahhoz, hogy az ionoszférikus késleltetés kiszámításához egy ionoszférikus modellt használjanak fel, és azt a 4. al-keret 18. oldala foglalja magába úgy, ahogy az a B-12. táblázatban meghatározásra került.

3.1.1.3.3.8 *Speciális közlemények.* A 4. al-keret 17. oldalát a speciális közlemények részére fenn kell tartani.

B-11. táblázat: Egyeztetett Világidő /UTC/ paraméterek

Paraméter	A bitek száma**	Osztás tényező (LSB)	Tényleges tartomány***	Mértékegység
A_0	32*	2^{-30}		másodperc
A_1	24*	2^{-50}		Másodperc/mp
Δt_{LS}	8*	1		másodperc
t_{ot}	8	2^{12}	602 112	másodperc
WN_t	8	1		hetek
WN_{LSF}	8	1		hetek
DN	8****	1	7	napok
Δt_{LSF}	8*	1		másodperc

* Az így jelzett paramétereknek két komplemenses összetevője van, a Legnagyobb helyértékű bitet /MSB/ elfoglaló (+ vagy -) előjel bittel.

** Lásd a B-6. ábrán a teljes bit kiosztást az al-keretben.

*** Ha ebben az oszlopban nincs másképpen jelezve, a tényleges tartomány az a maximális tartomány, ami a megadott bit kijelöléssel és osztás tényezővel elérhető.

**** Pontosan megerősített.

LSB = legkisebb helyértékű bit.

B-12. táblázat: Ionoszférikus paraméterek

Paraméter	A bitek száma**	Osztás tényező (LSB)	Tényleges tartomány***	Mértékegység
α_0	8*	2^{-30}		Másodperc
α_1	8*	2^{-27}		Másodperc/félkör
α_2	8*	2^{-24}		Másodperc/félkör^2
α_3	8*	2^{-24}		Másodperc/félkör^3
β_0	8*	2^{11}		Másodperc
β_1	8*	2^{14}		Másodperc/félkör
β_2	8*	2^{16}		Másodperc/félkor^2
β_3	8*	2^{16}		Másodperc/félkör^3

* Az így jelzett paramétereknek két komplemenses összetevője van, a Legnagyobb helyértékű bitet /MSB/ elfoglaló (+ vagy -) előjel bittel.
** Lásd a B-6. ábrán a teljes bit kiosztást az al-keretben.
*** Ha ebben az oszlopban nincs másképpen jelezve, a tényleges tartomány az a maximális tartomány, ami a megadott bit kijelöléssel és osztás tényezővel elérhető.

LSB = legkisebb helyértékű bit.

3.1.1.3.3.9 *Fenntartott adatmezők.* A 4. al-keret 3.-tól 10.-ig terjedő szavainak - kivéve az Adat azonosításra használt 58. bitet - a műhold (oldal) azonosítót, a paritás (az egyes szavak 6 legkisebb helyértékű bitjei) és a paritás számítási biteket (a 10. szó 23. és 24. bitjei), az 1., 6., 11., 12., 13., 14. 15., 16., 19., 20., 21., 22., 23. és 24. oldalon és azokat a naptár oldalakat, amelyek műhold azonosítója nulla, fenntartottként kell kijelölni. A további fenntartott biteknek a 4. és 5. al-keretben azoknak kell lenni, amit a B-13. táblázat bemutat. Az egyes szavakban a fenntartott bit helyeknek váltakozóan 1-es és 0-s bit alakzatot kell magába foglalni egy érvényes szó paritással.

3.1.2 AZ ADATFELHASZNÁLÓI PROTOKOLLOK MEGHATÁROZÁSA

Megjegyzés. – Ez a rész az adat sugárzási közlemények paraméterei közötti kölcsönhatást határozza meg. Ez azoknak a paramétereknek a meghatározásait adja meg, amelyek nem kerülnek továbbításra, de a nem-légijármű fedélzeti és a légijármű fedélzeti elemek valamelyikében, vagy mindkettőben használatosak, és amelyek meghatározzák azokat a tényezőket, amelyek a navigációs megoldásokra és azok sértetlenségére vonatkoznak.

B-13. táblázat: A 4. és 5. al-keretben lévő fenntartott bitek

Al-keret	Oldalak	Szavak	A fenntartott bitek helye a szóban
4	17	10	17 - 22
4	18	10	9 -22
4	25	8	17 - 18
4	25	10	19 - 22
5	25	10	4 - 22

B-14. táblázat: Paritás jel-átalakító algoritmusok

D_1	=	$d_1 \oplus D^*_{30}$
D_2	=	$d_2 \oplus D^*_{30}$
D_3	=	$d_3 \oplus D^*_{30}$

D_{24}	=	$d_{24} \oplus D^*_{30}$
D_{25}	=	$D^*_{29} \oplus d_1 \oplus d_2 \oplus d_3 \oplus d_5 \oplus d_6 \oplus d_{10} \oplus d_{11} \oplus d_{12} \oplus d_{13} \oplus d_{14} \oplus d_{17} \oplus d_{18} \oplus d_{20} \oplus d_{23}$
D_{26}	=	$D^*_{30} \oplus d_2 \oplus d_3 \oplus d_4 \oplus d_6 \oplus d_7 \oplus d_{11} \oplus d_{12} \oplus d_{13} \oplus d_{14} \oplus d_{15} \oplus d_{18} \oplus d_{19} \oplus d_{21} \oplus d_{24}$
D_{27}	=	$D^*_{29} \oplus d_1 \oplus d_3 \oplus d_4 \oplus d_5 \oplus d_7 \oplus d_8 \oplus d_{12} \oplus d_{13} \oplus d_{14} \oplus d_{15} \oplus d_{16} \oplus d_{19} \oplus d_{20} \oplus d_{22}$
D_{28}	=	$D^*_{30} \oplus d_2 \oplus d_4 \oplus d_5 \oplus d_6 \oplus d_8 \oplus d_9 \oplus d_{13} \oplus d_{14} \oplus d_{15} \oplus d_{16} \oplus d_{17} \oplus d_{20} \oplus d_{21} \oplus d_{23}$
D_{29}	=	$D^*_{30} \oplus d_1 \oplus d_3 \oplus d_5 \oplus d_6 \oplus d_7 \oplus d_9 \oplus d_{10} \oplus d_{14} \oplus d_{15} \oplus d_{16} \oplus d_{17} \oplus d_{18} \oplus d_{21} \oplus d_{22} \oplus d_{24}$
D_{30}	=	$D^*_{29} \oplus d_3 \oplus d_5 \oplus d_6 \oplus d_8 \oplus d_9 \oplus d_{10} \oplus d_{11} \oplus d_{13} \oplus d_{15} \oplus d_{19} \oplus d_{22} \oplus d_{23} \oplus d_{24}$

Ahol:
$D_1, D_2, D_3 \ldots D_{29}, D_{30}$ azok a bitek, amelyeket a műhold továbbított;
$D_{25} \ldots D_{30}$ a számított paritás bitek;
$d_1, d_2, \ldots d_{24}$ az eredeti adat bitek;
A $\oplus$ a Modulo-2, vagy a “Kizáró-Vagy” művelet; és
A * használatos az al-keret megelőző szava utolsó két bitjének azonosításához.

3.1.2.1. *Paritás algoritmus*. A Globális Helymeghatározó Rendszer /GPS/ paritás algoritmusa a B-14. táblázatban bemutatottaknak megfelelően került meghatározásra.

3.1.2.2 *Műhold óra helyesbítési paraméterek*. A Globális Helymeghatározó Rendszer /GPS/ rendszer ideje, a t meghatározása a következő:

$$t = t_{sv} - (\Delta t_{sv})_{L1}$$

Ahol:

t	=	A Globális Helymeghatározó Rendszernek a rendszer ideje (a kezdéssel és a Hét-vége átvezetéssel helyesbítve);
t_{sv}	=	A műhold ideje a közlemény továbbításakor;
$(\Delta t_{sv})_{L1}$	=	A műhold ál-véletlen zaj /PRN/ kód fázis-eltolása;

$$(\Delta t_{sv})_{L1} = a_{f0} + a_{f1}(t - t_{oc}) + a_{f2}(t - t_{oc})^2 + \Delta t_r - T_{GD}$$

Ahol:
a_{f0}, a_{f1} és a_{f2} és t_{oc} értékeket az 1. al-keret foglalja magába; és

Δt_r = A relativisztikus helyesbítési tényező (másodperc)

$$\Delta t_r^{\prime} = Fe\sqrt{A}\ \sin E_k$$

Ahol:
Az 'e' és az 'A' értékeket a 2. és 3. al-keret foglalja magába;
E_k a B-15. táblázatban került meghatározásra; és

$$F = \frac{-2\,(\mu)^{1/2}}{c^2} = -4.442807633(10)^{-10}\ \mathrm{s/m}^{1/2}$$

Ahol:

μ	=	Geodéziai Világrendszer /WGS-84/ egyetemes gravitációs paraméter ($3{,}986005 \times 10^{14}\ m^3/s^2$)
c	=	A fény sebessége a légüres térben ($2{,}99792458 \times 10^8$ m/s)

Megjegyzés. – A 't' értéke a hét-átmenetek kezdetének, vagy végének a számításba vételére szolgál. Ez azt jelenti, hogy ha a t-t_{oc} mennyisége 302 400 másodpercnél nagyobb, akkor 604 800 másodperc kerül a t-ből levonásra, és ha a t-t_{oc} mennyisége –302 400 másodpercnél kevesebb, akkor 604 800 másodperc kerül a t-hez hozzáadásra.

3.1.2.3 *Műhold helyzet*. A pillanatnyi műhold helyzet (X_k, Y_k, Z_k) úgy van meghatározva, ahogy azt a B-15. táblázat bemutatja.

3.1.2.4 *Ionoszférikus helyesbítés*. Az ionoszférikus helyesbítés (T_{iono}) a következők szerint van meghatározva.

$$T_{iono} = \left\{ \begin{array}{l} F \times \left[5{,}0 \times 10^{-9} + AMP\left(1 - \frac{x^2}{2} + \frac{x^4}{24}\right)\right], |x| < 1{,}57 \\ F \times \left(5{,}0 \times 10^{-9}\right), |x| \geq 1{,}57 \end{array} \right\} \text{(másodperc)}$$

$$AMP = \left\{ \begin{array}{l} \sum_{n=0}^{3} \alpha_n \phi_{m,}^{n} AMP \geq 0 \\ ha \\ AMP \prec 0, AMP = 0 \\ \end{array} \right\} (\text{másodperc})$$

$$x = \frac{2\pi(t - 50400)}{PER}, (\text{radián})$$

$$PER = \left\{ \begin{array}{l} \sum_{n=0}^{3} \beta_n \phi_{m,}^{n} PER \geq 72000 \\ ha \\ PER \prec 72000, PER = 72000 \\ \end{array} \right\} (\text{másodperc})$$

ahol:

$F = 1,0 + 16,0\ [0,53 – E]^3$

α_n és β_n a műhold által továbbított adat-szavak, n = 0, 1, 2 és 3-al

$\Phi m = \Phi i + 0,064 \cos(\lambda i – 1,617)$ (félkör)

$$\lambda_i = \lambda_u + \frac{\psi \sin A}{\cos \varphi_i} (\text{félkör})$$

$$\overline{\phi_i} = \phi_u + \psi \cos A (\text{félkör})$$

$$\phi_i = \left\{ \begin{array}{l} \phi_i = \overline{\phi_i}, \text{ha} \\ \left|\overline{\phi_i}\right| \leq 0{,}416 \\ \phi_i = +0{,}416, \text{ha} \\ \overline{\phi_i} \succ 0{,}416 \\ \phi_i = -0{,}416, \text{ha} \\ \overline{\phi_i} \prec -0{,}416 \end{array} \right\} (\text{félkör})$$

$\Psi = \frac{0{,}0137}{E + 0{,}11} - 0{,}022$ (félkör)

t = 4,32 x 10^4 λi + a Globális Helymeghatározó Rendszer /GPS/ ideje (másodperc), ahol
$0 \leq t < 86\,400$,
ennek megfelelően: ha $t \geq 86\,400$ másodperc, le kell vonni 86 400 másodpercet; és
ha $t < 0$ másodperc, hozzá kell adni 86 400 másodpercet.

E = a műhold magassági szöge

3.1.2.4.1 Az ionoszférikus késés kiszámításához használt tényezők a következők:

a) A műhold által kisugárzott tényezők:

α_n = a függőleges késés amplitúdóját képviselő harmadfokú egyenlet együtthatói (4 együttható = 8 bites mindegyikük);

β_n = a modell periódusát képviselő harmadfokú egyenlet együtthatói (4 együttható = 8 bites mindegyikük);

b) A vevő által létrehozott tényezők:

E = A felhasználó és a műhold közötti magassági szög (félkör)

A = A felhasználó és a műhold közötti oldalszög a földrajzi Északtól az órajárással megegyező pozitívként mérve

Φ_u = A felhasználó geodéziai szélességi fok értéke (félkör), Geodéziai Világrendszer – 84 /WGS-84/

λ_u = A felhasználó geodéziai hosszúsági fok értéke (félkör), Geodéziai Világrendszer – 84 /WGS-84/

GPS idő = A vevő által kiszámított rendszer idő

c) Számított tényezők:

x = Fázis (radián)

F = Elhajlási tényező (dimenzió nélküli)

t = Helyi idő (másodperc)

Φ_m = Az ionoszférikus metszési pont földi vetületének föld-mágnesességi szélességi foka (a közepes ionoszfériai magasságot 350 km-ként elfogadva) (félkör)

λ_i = Az ionoszférikus metszési pont földi vetületének föld-mágnesességi hosszúsági foka (a közepes ionoszfériai magasságot 350 km-ként elfogadva) (félkör)

Φi = Az ionoszférikus metszési pont földi vetületének föld-mágnesességi szélességi foka (félkör)

Ψ = Földi középponti szög a felhasználó helyzete és az ionoszférikus metszési pont földi vetülete között (félkör)

B-15. táblázat: A koordináta rendszerek elemei

$A = (\sqrt{A})^2$	Fél-nagytengely
$n_0 = \sqrt{\dfrac{\mu}{A^3}}$	Számított közepes szögsebesség
$t_k = t - t_{oe}$	Idő az efemerisz referencia korszakától*
$n = n_0 + \Delta n$	Helyesbített szögsebesség
$M_k = M_0 + nt_k$	Átlagos anomália
$M_k = E_k - e \sin E_k$	Kepler-egyenlet az excentricitási anomáliára (lépésenkénti megközelítéssel megoldható)
$v_k = \tan^{-1}\left\{\dfrac{\sin v_k}{\cos v_k}\right\} = \tan^{-1}\left\{\dfrac{\sqrt{1-e^2}\sin E_k/(1-e\cos E_k)}{(\cos E_k - e)/(1-e\cos E_k)}\right\}$	Valós anomália
$E_k = \cos^{-1}\left\{\dfrac{e+\cos v_k}{1+e\cos v_k}\right\}$	Excentrikus anomália
$\phi_k = v_k + \omega$	Szélességi fok

Második harmonikus zavaró hatások

$\delta u_k = C_{us}\sin 2\phi_k + C_{uc}\cos 2\phi_k$	Szélességi fok helyesbítés
$\delta r_k = C_{rc}\sin 2\phi_k + C_{rs}\sin 2\phi_k$	Sugár helyesbítés
$\delta i_k = C_{ic}\cos 2\phi_k + C_{is}\sin 2\phi_k$	Mágneses elhajlás /inklináció/ helyesbítés
$u_k = \phi_k + \delta u_k$	Helyesbített szélességi fok
$r_k = A(1 - e\cos E_k) + \delta r_k$	Helyesbített sugár
$i_k = i_0 + \delta i_k + (iDOT)t_k$	Helyesbített mágneses elhajlás /inklináció/
$\left.\begin{array}{l} x'_k = r_k \cos u_k \\ y'_k = r_k \sin u_k \end{array}\right\}$	Helyzetek az orbitális síkban
$\Omega_k = \Omega_0 + (\dot{\Omega} - \dot{\Omega}_e)t_k - \dot{\Omega}_e t_{oe}$	Felszálló csomópont helyesbített földrajzi hosszúsága
$\left.\begin{array}{l} x_k = x'_k\cos\Omega_k - y'_k\cos i_k\sin\Omega_k \\ y_k = x'_k\sin\Omega_k - y'_k\cos i_k\cos\Omega_k \\ z_k = y'_k\sin i_k \end{array}\right\}$	Föld-középpontú, Föld-állandó koordináták

* A ’t’ a Globális Helymeghatározó Rendszer /GPS/ rendszer ideje az adattovábbítás időpontjában, azaz a GPS ideje a “repülési idő”-re helyesbítve (távolság/fénysebesség). Továbbá a ’t_k’ a tényleges teljes idő különbség a ’t’ idő és a korszak idő, a ’t_{oe}’ között, és számításba kell venni az átvezetéseket, a kezdetet vagy a hét-véget. Ami, ha a ’t_k’ 302 400 másodpercnél nagyobb, le kell vonni 604 800 másodpercet a ’t_k’-ból. Ha a ’t_k’ kevesebb, mint –302 400 másodperc, hozzá kell adni 604 800 másodpercet a ’tk’-hoz.

3.1.3 LÉGIJÁRMŰ FEDÉLZETI ALKOTÓELEMEK

3.1.3.1 *Globális Navigációs Műhold Rendszer /GNSS/ (Globális Helymeghatározó Rendszer /GPS/) vevő*

3.1.3.1.1 *Műhold kizárás*. A vevőnek ki kell zárni minden olyan műholdat, amelyet nem megfelelő működési állapotúnak jelöl ki a Globális Helymeghatározó Rendszer /GPS/ műhold efemerisz működési állapot hibajelzése.

3.1.3.1.2 *Műhold követés*. A vevőnek biztosítania kell azt a képességet, hogy folyamatosan nyomon kövessen minimum négy műholdat, és létre kell hoznia az azokon a méréseken alapulóan egy helymeghatározási megoldást.

3.1.3.1.3 *Doppler eltolódás*. A vevőnek képesnek kell lenni arra, hogy a dinamikus Doppler eltolódás hatását kiegyenlítse a névleges Szabvány Helymeghatározási Szolgáltatás /SPS/ jelének vivőhullám fázisán és a Torzított /durva/ Hozzáférési /C/A/ kód méréseknél. A vevőnek ki kell egyenlíteni azt a Doppler eltolódást, ami a várt alkalmazáshoz egyértelműen hozzátartozik.

3.1.3.1.4 *Interferencia ellenálló képesség*. A vevőnek ki kell elégítenie a 3. Fejezet 3.7 pontjában meghatározott interferencia ellenállósági követelményeket.

3.1.3.1.5 *Az óra és eferemerisz adatok alkalmazása*. A vevőnek biztosítania kell azt, hogy csak a pontos efemerisz és óra adatokat használja fel, mielőtt bármilyen helymeghatározási megoldást adna. A vevőnek ellenőriznie kell az Adatkibocsátás, Óra /IODC/ és az Adatkibocsátás, Efemerisz /IODE/ értékeket, és fel kell frissítenie az efemerisz és óra adatbázisát, ha ezen értékek valamelyikénél, vagy mindkettőnél egy változást észlel. A Szabvány Helymeghatározási Szolgáltatás /SPS/ vevőnek az óra és efemerisz adatokat egy adott műhold megfelelő Adatkibocsátás, Óra /IODC/ és Adatkibocsátás, Efemerisz /IODE/ adataival kell felhasználnia.

3.1.4 IDŐ

A Globális Helymeghatározó Rendszer /GPS/ idejét az Egyeztetett Világidőre /UTC/ kell vonatkoztatni (az Egyesült Államok Tengerészeti Obszervatóriuma által kezelten), a nulla idő-pont az 1980. január 5. este/1980. január 6. reggel közötti éjfélnél került meghatározásra. A GPS idejének megállapításához használt legnagyobb egységnek az 1 hétnek kell lenni, ami 604 800 másodpercként van meghatározva. A Globális Helymeghatározó Rendszer /GPS/ időléptékét az Egyeztetett Világidő /UTC/ 1 mikromásodpercen belül kell tartani (Modulo 1 másodperc) a szökő másodperc különbség egészszámú helyesbítése után. A navigációs adatoknak magukba kell foglalniuk a Globális Helymeghatározó Rendszer /GPS/ idejének az Egyeztetett Világidőre /UTC/ vonatkoztató követelmény adatait.

3.2 Globális Navigációs Műhold Rendszer (GLONASS) Szabvány pontosságú csatorna (CSA) (L1)

Megjegyzés. – Ebben a részben a GLONASS kifejezés a konstellációbn lévő összes műholdra utal. A csak a Modernizált Globális Navigációs Műhold Rendszer (GLONASS-M) műholdakra vonatkozó Szabványok ennek megfelelően vannak minősítve.

3.2.1 NEM-LÉGIJÁRMŰ FEDÉLZETI ALKOTÓELEMEK

3.2.1.1 *Rádiófrekvenciás /RF/ jellemzők*

3.2.1.1.1 *Vivőhullám frekvenciák*. Az L1 névleges értékének és a vivőhullám frekvenciáknak azoknak kell lenni, amit a következő kifejezések meghatároznak:

$$f_{k1} = f_{01} + k\Delta f_1$$

ahol:

k = -7, …, 0, 1, …, 13 a vivőhullám számok (frekvencia csatornák) a Globális Navigációs Műhold Rendszer /GLONASS/ műholdjai által továbbított jelek részére az L1 al-sávokban;

f_{01} = 1 602 MHz; és

Δf_1 = 0,5625 MHz.

A vivőhullám frekvenciákat egy, a fedélzeten lévő közös idő/frekvencia szabvány rendszerből kell folyamatosan származtatni. A frekvencia névleges értékének a földről érzékelten 5,0 MHz-el kell egyenlőnek lenni. A Globális Navigációs Műhold Rendszer /GLONASS/ műhold vivőhullám frekvenciájának a névleges értékéhez, az fk-hoz viszonyítottan $\pm 2 \times 10^{-11}$-en belül kell lenni.

1. Megjegyzés. – A vivőhullám frekvenciák /frekvencia csatornák/ vivőhullám frekvenciáinak névleges értéke, a 'k' a B-16. táblázatban került megadásra.

2. Megjegyzés. – A GLONASS-M műholdaknál a szabvány pontosságú (CSA) navigációs jel L2 csatornája az 1 242,9375 – 1 251,6875 MHz ± 0,511 MHz sávszélességet foglalja el, ahogy azt a következő kifejezések meghatározzák:

$$f_{k2} = f_{02} + k\Delta f_2,$$

$$f_{02} = 1\,246 \text{ MHz}; \Delta f_2 = 0{,}4375 \text{ MHz}.$$

Az L1 és L2 al-sávok vivőhullám frekvenciáinak minden adott 'k' arány értéke egyenlő lesz:

$$\frac{f_{k2}}{f_{k1}} = \frac{7}{9}$$

B-16. táblázat: Az L1 vivőhullám frekvenciái

Vivőhullám szám	H^A_n (lásd 3.2.1.3.4 pontot)	Az L1 al-sávban lévő frekvenciák névleges értéke (MHz)
13*	13	1 609,3125
12**	12	1 608,7500
11**	11	1 608,1875
10**	10	1 607,6250
09**	9	1 607,0625
08**	8	1 606,5000
07**	7	1 605,9375
06***	6	1 605,3750
05***	5	1 604,8125
4	4	1 604,2500
3	3	1 603,6875
2	2	1 603,1250
1	1	1 602,5625
0	0	1 602,0000
-1	31	1 601,4375
-2	30	1 600,8750
-3	29	1 600,3125
-4	28	1 599,7500
-5	27	1 599,1875
-6	26	1 598,6250
-7	25	1 598,0625

* Ezt a frekvenciát az Orosz Államszövetség felett technikai célokra lehet felhasználni 2006. előtt és a “megszületését” 2005. utánra tervezik.
** Ezeknek a frekvenciáknak a “megszületését” 2005. utánra tervezik.
*** Ezeket a frekvenciákat az Orosz Államszövetség felett 2005. után lehet technikai célokra felhasználni.

3.2.1.1.2 *Vivőhullám fázis zaj*. A modulálatlan vivőhullám fázis zajának spektrális sűrűsége olyan kell, hogy legyen, hogy egy fázisszabályzó hurok 10 Hz-es egy-oldalas zajszűrővel egy, a 0,1 radiánnál (1 szigma) nem rosszabb vivőhullám fáziskövetési pontosságot biztosítson.

3.2.1.1.3 *A GLONASS ál-véletlen zaj kód generálása*. Az ál-véletlen távolságmérő kódnak egy olyan 511 bites sorozatnak kell lenni, ami egy 9-fokozatú léptető-tároló hetedik fokozatának kimenetén kerül mintavételezésre. Az ennek a sorozatnak a létrehozásához a kezdő érték beállító sorozatnak ”111111111”-nek kell lenni. Annak a generáló polinomnak, ami a 9-fokozatú léptető-tárolónak megfelel:

$$G(x)= 1 + x^5 + x^9\text{-nek kell lenni.}$$

3.2.1.1.4 *Hamis sugárzás*. A GLONASS kijelölt sávszélességén túl a kisugárzott rádiófrekvenciás /RF/ jel teljesítménye a modulálatlan vivőhullám teljesítményéhez viszonyítva nem lehet -40 dB-nél több.
1. Megjegyzés. – Azok a GLONASS műholdak, amelyek az 1998.-tól 2005.-ig terjedő évek során és azután kerülnek pályára állításra, a Nemzetközi Rádió Tanácsadó Bizottság /CCIR/ 769. Ajánlásában található, a káros interferencia határokra vonatkozó sávon kívüli sugárzásokat kiszűrő határoló szűrőket fognak felhasználni az 1 660 – 1 670 MHz-es sávra.

2. Megjegyzés. – Azok a GLONASS műholdak, amelyek 2005. után kerülnek pályára állításra, a Nemzetközi Rádió Tanácsadó Bizottság /CCIR/ 769. Ajánlásának megfelelő – a káros interferencia határokra vonatkozó – sávon kívüli sugárzásokat kiszűrő határoló szűrőket fognak felhasználni az 1610,6 – 1613,8 MHz-es és 1 660 – 1 670 MHz-es sávra.

3.2.1.1.5 *Korrelációs veszteség*. A visszanyert jel teljesítményében a jel moduláció hiányossága és a hullámforma torzítás miatti veszteség nem haladhatja meg a 0,8 dB-t.

Megjegyzés. – A jel-teljesítmény veszteség az egy 1,022 MHz-es sáv-szélességben kisugárzott teljesítmény és az egy zajmentes veszteségmentes 1-chip korrelációs térközű és egy 1,022 MHz-es sávszélességű vevővel visszanyert jel-teljesítmény közötti különbség.

3.2.1.2 *Adat szerkezet*

3.2.1.2.1 *Általános*. A navigációs közleményt egy olyan digitális adat alakzatban kell továbbítani, amely a Hamming kód szerint kódolt, és relatív kódolásba kerül átalakításra. Szerkezetileg az adat alakzatot folyamatosan ismétlődő szuperkeretenként kell létrehozni. A szuperkereteknek kell magukba foglalniuk a kereteket és a kereteknek kell tartalmazniuk a jelsorozatokat. A különböző GLONASS modulok navigációs közleményei, jelsorozatai, keretei és szuperkeretei határait 2 milliszekundumon belülre szinkronizálni kell.

3.2.1.2.2 *A szuperkeret szerkezete*. A szuperkeretnek 2,5 perc időtartamúnak kell lenni, és 5 keretet kell magába foglalni. Az egyes szuperkereteken belül a nem-közvetlen információk teljes tartalmát (24 GLONASS műhold naptárját) kell leadni.

Megjegyzés. – A szuperkeret szerkezetét, a szuperkeretben lévő keret számokkal és a keretekben lévő jelsorozat számokkal a B-7. ábra mutatja be.

3.2.1.2.3 *A keret szerkezete*. Az egyes kereteknek 30 másodperces időtartamúnak kell lenni, és 15 jelsorozatot kell magába foglalni. Az egyes kereteken belül a közvetlen információk (efemerisz és idő paraméterek) teljes tartalmát az adott műholdra és a nem-közvetlen információk (naptár) egy részét kell leadni. Az 1.-től 4.-ig terjedő kereteknek 20 műholdra vonatkozó naptár adat részt (keretenként 5 műhold) kell magukba foglalniuk, és az 5. keretnek kell a 4 műhold fennmaradó naptár adatait tartalmazni. Egy műhold naptár adatainak két jelsorozatot kell lefoglalni.

Megjegyzés. – A keret szerkezeteket a B-8. és B-9. ábrák mutatják be.

3.2.1.2.4 *A jelsorozat szerkezete*. Az egyes jelsorozatoknak 2 másodperc időtartamúnak kell lenni, és az adatok bináris chipjeit, valamint az időjelet kell magukba foglalniuk. Ezen a 2 másodperces időtartamon belül az utolsó 0,3 másodperc során (az egyes jelsorozatok végénél) az időjelet kell továbbítani. Az időjelnek (rövidített ál-véletlen sorozat) 30 chipet kell magába foglalni, az egyes chipek 10 milliszekundum időtartamúak, és a következő sorrendjük van:

1 1 1 1 1 0 0 0 1 1 0 1 1 1 0 1 0 1 0 0 0 0 1 0 0 1 0 1 1 0.

A 2 másodperces időtartam első 1,7 másodperce során (az egyes jelsorozatok kezdeténél) 85 adatbitet (az egyes adatbiteket egy 20 milliszekundumos időtartammal) kell továbbítani bi-bináris formában. A jelsorozatban a bitek számát jobbról balra kell növelni. Az információs bitekkel együtt (a 9.-től a 84.-ig terjedő bit helyzetűek) a Hamming kód (KX) ellenőrző bitjeit (az 1.-től a 8.-ig terjedő bit helyzetűek) kell leadni. A Hamming kód kódhosszának 4-nek kell lenni. Egy jelsorozat adatait a szomszédos jelsorozat adataitól az időjellel (MB) kell elválasztani. Az adatok szavait az elől elhelyezett Legnagyobb Helyértékű Bittel /MSB/ kell bejegyezni. Minden egyes jelsorozat bit helyzetben 85 bitnek egy tétlen chipnek (”0”) kell lenni, és azt kell először továbbítani.

3.2.1.2.4.1 *Az 1.-től a 4.-ig terjedő jelsorozatok.* Az egyes keretek 1.-től 4.-ig terjedő jelsorozataiban foglalt információk annak a műholdnak kell, hogy megfeleljenek, amelyről az leadásra került. Ezt az információt a szuperkereten belül nem lehet megváltoztatni.

3.2.1.2.4.2 *Az 5.-től a 15.-ig terjedő jelsorozatok.* Az egyes keretek 5.-től a 15.-ig terjedő jelsorozatainak kell magukba foglalniuk 4, vagy 5 műhold GLONASS naptárját. Az ötödik jelsorozatban foglalt információkat a szuperkeret minden egyes keretében meg kell ismételni.

Megjegyzés. – A jelsorozatok szerkezetét a B-10. ábra adja meg.

3.2.1.3 *Adattartalom*

3.2.1.3.1 Efemerisz és idő paraméterek. Az efemerisz és idő paramétereknek a következőknek kell lenniük:

m = Jelsorozat szám a kereten belül;

t_k = Az adott napon belül a keret kezdési időpontjához viszonyított idő. Ez a műhold idő-skálájának megfelelően kerül kiszámításra. Az adott nap kezdete óta eltelt órák egész számmal kifejezve az 5. Legnagyobb Helyértékű bitben /MSB/ vannak bejegyezve. Az adott óra kezdete óta eltelt percek egész számmal kifejezve a következő 6 bitben vannak bejegyezve. Az adott perc kezdete óta eltelt 30 másodperces időtartamok az egy Legkisebb Helyértékű bitben /LSB/ van bejegyezve. A műhold idő-skálája szerinti nap kezdete egybeesik az ismétlődő szuperkeretek kezdetével;

t_b = Az adott napon belüli időköz az Egyeztetett Világidő /UTC/(SU) + 03 óra 00 percnek megfelelően. A kereten belül leadott közvetlen adatok a t_b közepére vannak vonatkoztatva. Az időköz hossza és ennek megfelelően a t_b maximális értéke a P1 jelzés értékétől függ;

$\gamma_n(t_b)$ = n-műhold előre jelzett vivőhullám frekvencia értékének relatív eltérése a névleges értéktől a t_b pillanatnyi időpontjánál, azaz:

$$\gamma_n(t_b) = \frac{f_n(t_b) - f_{Hn}}{f_{Hn}}$$

ahol:

$f_n(t_b)$ = n-műhold óráinak előre jelzett frekvenciája egy t_b pillanatnyi időpontnál;

f_{Hn} = n-műhold óráinak névleges frekvencia értéke;

tn(tb) = A helyesbítés n-műhold idejéhez t_n, a GLONASS idejéhez t_c viszonyítva, egy t_b pillanatnyi időpontnál, azaz:
$t_n(t_b) = t_c(t_b) - t_n(t_b)$

$x_n(t_b), y_n(t_b), z_n(t_b)$ = n-műhold koordinátája a PZ-90 koordináta rendszerben megadva egy t_b pillanatnyi időpontnál;

$\dot{x}_n(t_b), \dot{y}_n(t_b), \dot{z}_n(t_b)$ = n-műhold sebességi vektor összetevője a PZ-90 koordináta rendszerben megadva egy t_b pillanatnyi időpontnál;

$\ddot{x}_n(t_b)$, $\ddot{y}_n(t_b)$, $\ddot{z}_n(t_b)$ = n-műhold azon gyorsulási összetevői a PZ-90 koordináta rendszerben megadva egy t_b pillanatnyi időpontnál, amelyet a nap és a hold hatása okoz;

En = A közvetlen információk "korának" jelzése, azaz az az időköz, ami azok kiszámításának pillanatnyi ideje (adattöltés) óta eltelt az n-műhold pillanatnyi t_b idejéig;

B_n = A működési állapot jelzés. A 3-nál nagyobb értékek az adott műhold működési hibájának tényét jelzik;

P1 = Jelzés, amely a t_b paraméterek pillanatnyi és korábbi értéke közötti időközt jelzi percekben az itt bemutatottak szerint:

P1	Időköz a szomszédos t_b értékek között, percekben
0	0
1	30
10	45
11	60

P2 = Jelzés arról, hogy a t_b értéke páratlan vagy páros. Az "1"-érték egy 30 perces időközt jelez a szolgáltatási információk továbbításánál (t_b = 1, 3, 5 …), a "0"- érték egy 60 perces időközt jelez a szolgáltatási információk továbbításánál (t_b = 2, 6, 10 …);

P3 = Jelzés, ami azoknak a műholdaknak a számát adja meg, amelyekre egy naptár kerül továbbításra egy adott kereten belül. Az "1" 5 műholdnak felel meg és a "0" négy műholdat jelent; és

Δt_n = Az adott műhold által az L2 al-sávban leadott navigációs rádiófrekvenciás /RF/ jel és az L1 sávban leadott navigációs rádiófrekvenciás jel közötti időkülönbség:

$$\Delta t_n = t_{f2} - t_{f1}$$

Ahol:
a t_{f1}, t_{f2} az L1 és L2 al-sávokban a berendezés késés külön-külön, időegységben kifejezve.

3.2.1.3.2 *Efemerisz és idő paraméterek.* Az efemerisz és idő paramétereknek a B-17. táblázatban bemutatottaknak kell lenni. Azoknál a szavaknál, amelyek számszerű értékei pozitívak, vagy negatívak lehetnek, a Legnagyobb Helyértékű Bitnek kell az előjel bitnek lenni. A "0" chipnek kell a "+" előjelnek és az "1" chipnek kell a "-" előjelnek megfelelni.

3.2.1.3.3 *Az efemerisz és idő paraméterek elrendezése.* Az efemerisz és idő paraméterek elrendezésének a kereten belül a B-18. táblázatban feltüntetettnek megfelelő elrendezésűnek kell lenni.

3.2.1.3.4 *Naptár paraméterek.* A naptár paramétereknek a következőknek kell lenniük:

A = Egy mutató, amely ennek a paraméternek a naptárral való kapcsolatát mutatja;

M^A_n = Egy, az n^A-műhold változatot jelző mutató: a “00” a GLONASS műholdat jelzi, és a “01” a GLONASS-M műhold jelzése;

τ_c = A GLONASS idő-skála helyesbítése az Egyeztetett Világidő /UTC/(SU) idejéhez. A τ_c helyesbítés az N^A nap pillanatnyi idejéhez van megadva;

N^A = A naptári nap száma a 4-éves időtartamon belül a szökőév óta. A τ_c helyesbítés és a további naptár adatok (a keringések naptára és a fázisok naptára) erre a nap számra vonatkoznak;

n^A = Az n-műhold által elfoglalt sorszám;

H^A_n = Az n^A-műhold vivőhullám frekvenciájának csatorna száma (B-16. táblázat);

λ^A_n = Az n^A-műhold keringési pályájának első (az N^A napon belül) felszálló csomójának földrajzi hosszúsága a PZ-90 koordináta rendszerben;

$t\lambda^A_n$ = Az n^A-műhold első felszálló csomójának áthaladási ideje az N^A napon belül;

B-17. táblázat: Efemerisz és idő paraméterek

Paraméter	A bitek száma	Osztás tényező (LSB)	Tényleges tartomány	Egységek
m	4	1		Dimenzió nélküli
	5	1	0-tól 23-ig	óra
t_k	6	1	0-tól 59-ig	perc
	1	30	0, vagy 30	másodperc
t_b	7	15	15…1 425	perc
$\gamma_n(t_b)$	11	2^{-40}	$\pm 2^{-30}$	Dimenzió nélküli
$\tau_n(t_b)$	22	2^{-30}	$\pm 2^{-9}$	másodperc
$x_n(t_b)$, $y_n(t_b)$, $z_n(t_b)$	27	2^{-11}	$\pm 2{,}7 \times 10^{4}$	km
$\dot{x}_n(t_b)$, $\dot{y}_n(t_b)$, $\dot{z}_n(t_b)$	24	2^{-20}	$\pm 4{,}3$	km/másodperc
$\ddot{x}_n(t_b)$, $\ddot{y}_n(t_b)$, $\ddot{z}_n(t_b)$	5	2^{-30}	$\pm 6{,}2 \times 10^{-9}$	km/másodperc^2
E_n	5	1	0-tól 31-ig	nap
B_n	3	1	0-tól 7-ig	Dimenzió nélküli
P1	2	Ahogy az a 3.2.1.3.1 pontban részletezésre került		
P2	1	1	0; 1	Dimenzió nélküli
P3	1	1	0; 1	Dimenzió nélküli
$\Delta\tau_n$	5	2^{-30}	$\pm 13{,}9 \times 10^{-9}$	másodperc

B-18. táblázat: Az efemerisz és idő paraméterek elrendezése a kereten belül

Paraméter	Bitek száma	Jelsorozat szám a kereten belül	Bit szám a kereten belül
m	4	1…15	81 – 84
t_k	12	1	65 – 76
t_b	7	2	70 – 76
$\gamma_n(t_b)$	11	3	69 – 79
$\tau_n(t_b)$	22	4	59 – 80
$x_n(t_b)$	27	1	9 – 35
$y_n(t_b)$	27	2	9 – 35
$z_n(t_b)$	27	3	9 – 35
$\dot{x}_n(t_b)$	24	1	41 – 64
$\dot{y}_n(t_b)$	24	2	41 – 64
$\dot{z}_n(t_b)$	24	3	41 – 64
$\ddot{x}_n(t_b)$	5	1	36 – 40
$\ddot{y}_n(t_b)$	5	2	36 – 40
$\ddot{z}_n(t_b)$	5	3	36 – 40
E_n	5	4	49 – 53
B_n	3	2	78 – 80
P1	2	1	77 – 78
P2	1	2	77
P3	1	3	80
$\Delta\tau_n$	5	4	54 – 58

3.2.1.3.5 *A naptár adatok elkülönítése és kódolása*. A szuperkeretben leadott GLONASS naptárt a szuperkereten keresztül el kell különíteni úgy, ahogy az a B-19. táblázatban megadásra került. A naptár paraméterek szám értékeinek pozitívnak, vagy negatívnak kell lenni. A Legnagyobb Helyértékű Bitnek kell az előjel bitnek lenni, a „0” chip a „+” előjelnek kell, hogy megfeleljen, és az „1” chip feleljen meg a „-” előjelnek. A naptár paramétereket a B-20. táblázatban megadottaknak megfelelően kell kódolni.

3.2.1.3.6 *A naptár paraméterek elrendezése*. A naptár szavaknak a kereten belüli elrendezése a B-21. táblázatban megadottaknak megfelelő kell, hogy legyen.

3.2.1.4 A *GLONASS-M műholdak által sugárzott kiegészítő adatok tartalma és szerkezete*

3.2.1.4.1 *A kiegészítő adatok betűjelzése*. A GLONASS adatokhoz kiegészítőleg a GLONASS-M műholdaknak a következő kiegészítő adatokat kell sugározniuk, ahogy az a B-17A táblázatban bemutatásra került:

n - az adott navigációs jelet sugárzó műhold jelző száma: ez a GLONASS műhold-rendszeren belüli sorszámnak felel meg;

l_n - a működési állapot jelzés ('egészség') az n-ik műholdra: a „0" jelzi azt, hogy az n-ik műhold jó működési állapotú, az „1" pedig azt, hogy az n-ik műhold hibásan működik;

B1 - a ΔUT1 meghatározásának együtthatója: ez az UT1 és az UTC közötti különbséggel egyenlő, a nap (N^A) kezdetén másodpercekben kifejezve;

B2 - a ΔUT1 meghatározásának együtthatója: ez a ΔUT1 különbségének napi változásával egyenlő (egy közepes nap szerinti /égitest/ napra másodpercekben kifejezve).

Ezeket az együtthatókat kell felhasználni az UTC(SU) és az UT1 közötti átalakításhoz:

$$\Delta UT1 = UTC(SU) - UT1,$$

ahol:

UT1 - a Közepes Greenwech-i délkörre (a Pólusok mozgását számításba véve) vonatkoztatott Egyeztetett Világidő /UTC/;

UTC(SU) - az Orosz Államszövetség Állami Szabványa szerinti koordinált Egyeztetett Világidő.

$$\Delta UT1 = B1 + B2 \text{ x } (N_T - N^A),$$

KP - értesítés az UTC(± 1 s) elkövetkező szökő-másodperc helyesbítéséről a bemutatottak szerint:

KP	UTC másodperc helyesbítési adat
00	Nincs UTC helyesbítés a jelenlegi negyed végén
01	UTC helyesbítés plusz 1 s-al a jelenlegi negyed végén
11	UTC helyesbítés mínusz 1 s-al a jelenlegi negyed végén

Megjegyzés. – A GLONASS rendszer időléptékének helyesbítésére általában évente egyszer éjfélkor 00 óra 00 perc 00 másodperckor kerül sor a Nemzetközi Idő Hivatal (BIH/BIPM) előzetes értesítésének megfelelően, a negyedév végén:

December 31-től Január 1-ig - első negyed,
Március 31-től Április 1-ig - második negyed,
Június 30-tól Július 1-ig - harmadik negyed,
Szeptember 30-tól Október 1-ig - negyedik negyed.

N_T - a jelenlegi dátum, a nap naptári száma a szökőév január 1-vel kezdődő négyéves időtartamán belül;

Megjegyzés. – Az N_T-nek, a jelenlegi dátumnak az általános formájú információra (dd/mm/yy)(nap/hónap/év) történő átalakítását a D-Melléklet 4.2.7.1 pontja mutatja be.

N_4 - a négyéves időtartam száma 1996-tól kezdődően;

F_T - egy paraméter, amely megadja az előre jelzett műhold felhasználói távolság pontosságot a t_b időpontban. A kódolást B-17-B. táblázat mutatja be.

M - a navigációs jelet sugárzó műhold típusa. A 00 vonatkozik a GLONASS műholdra és a 01 utal a GLONASS-M műholdra.

P4 - egy jelzés, amely azt mutatja, hogy felfrissített efemerisz adatok állnak rendelkezésre. Az „1” azt jelzi, hogy a vezérlő szegmens egy felfrissített efemerisz, vagy frekvencia/idő paramétert táplált be.

Megjegyzés. – A felfrissített efemerisz, vagy frekvencia/idő információ a következő időközben kerül betáplálásra, a jelenlegi időköz, a t_b végét követően.

P - a vezérlő szegmens technológiai paramétere, amely jelzi a műhold üzemelési módját az idő paraméterekre vonatkozólag:

00 - a t_c paraméter a vezérlő szegmensből van továbbítva, a t_{GPS} paraméter a vezérlő szegmensből van továbbítva;
01 - a t_c paraméter a vezérlő szegmensből van továbbítva, a t_{GPS} paraméter a GLONASS-M műhold fedélzetén került kiszámításra;
10 - a t_c paraméter a GLONASS-M műhold fedélzetén került kiszámításra, a t_{GPS} paraméter a vezérlő szegmensből van továbbítva;

11 - a t_c paraméter a GLONASS-M műhold fedélzetén került kiszámításra, a t_{GPS} paraméter a GLONASS-M műhold fedélzetén került kiszámításra;
tGPS - a GPS idő helyesbítése a GLONASS időhöz viszonyítva:

$$T_{GPS} – T_{GL} = \Delta T + t_{GPS},$$

ahol:

ΔT az egészszámú része és a t_{GPS} a tört része a másodpercekben kifejezett rendszer idő-léptékek közötti különbségnek.

Megjegyzés. – Az egészszámú részt, a ΔT-t a GPS navigációs közleményből határozza meg a felhasználó vevője.

$M^A{}_n$ – az n^A műhold típusa: a „00” kódolás jelzi a GLONASS műholdat, a „01” kódolás pedig a GLONASS-M műholdat jelzi.

3.2.1.4.2 *Kiegészítő adat paraméterek*. A kiegészítő adat paraméterek a B-17-A.-tól a B-18-A.-ig terjedő táblázatokban kerültek meghatározásra.

3.2.1.4.3 *A kiegészítő adat szavak elhelyezése a GLONASS-M navigációs közleményben*. A kiegészítő adat szavaknak a GLONASS-M navigációs közleményben való elhelyezésének szükséges helye a B-18-A. táblázatban került meghatározásra.

B-17-A. táblázat: Kiegészítő adat paraméterek

Paraméterek	A bitek száma	Osztás tényező (LSB)	Mérési tartomány	Mértékegység
n	5	1	0-tól 31-ig	Dimenzió nélküli
1_n	1	1	0; 1	Dimenzió nélküli
B1	11	2^{-10}	±0,9	Másodperc
B2	10	2^{-16}	(–4,5-től 3,5-ig) × 10^{-3}	Másodperc/közepes nap szerinti nap
KP	2	1	0-tól 3-ig	Dimenzió nélküli
N_T	11	1	0-tól 1 461-ig	Napok
N_4	5	1	1-től 31-ig	Négyéves időköz
F_T	4		Lásd a B-17-B. táblázatot.	
M	2	1	0-tól 3-ig	Dimenzió nélküli
P4	1	1	0; 1	Dimenzió nélküli
P	2	1	00,01,10,11	Dimenzió nélküli
τ_{GPS}	22	2^{-30}	±1,9 × 10^{-3}	Másodpercek
M^A_n	2	1	0-tól 3-ig	Dimenzió nélküli

C^A_n	1	6, 8, 10, 12, 14	80

Megjegyzés. – A szuperkereten belüli első négy keret jelsorozat számai vannak megadva. Nincs naptár paraméter az 5. keret 14. és 15. jelsorozatában.

3.2.2 AZ ADATFELHASZNÁLÓI PROTOKOLOK MEGHATÁROZÁSA

Megjegyzés. – Ez a rész az adat sugárzási közlemények paraméterei közötti kölcsönhatást határozza meg. Ez azoknak a paramétereknek a meghatározásait adja meg, amelyek nem kerülnek továbbításra, de a nem-légijármű fedélzeti és a légijármű fedélzeti elemek valamelyikében, vagy mindkettőben használatosak, és amelyek meghatározzák azokat a tényezőket, amelyek a navigációs megoldásokra és azok sértetlenségére vonatkoznak.

B-22. táblázat: Paritás ellenőrző algoritmus

b85, b84, … , b10, b9 az adat bitek (a helyzetük a 9.-től a 85.-ig terjedő a jelsorozatban);
β1, β2, … , β8 a Hamming kód ellenőrző bitjei (helyzetük 1.-től a 8.-ig terjed a jelsorozatban);
$c_1, c_2, \dots, c_7, c_\Sigma$ a következők felhasználásával összeállított ellenőrző összegek:

$c_1 = \beta \oplus [\Sigma_i\, b_i]_{mod2}$

i = 9, 10, 12, 13, 15, 17, 19, 20, 22, 24, 26, 28, 30, 32, 34, 35, 37, 39, 41, 43, 45, 47, 49, 51, 53, 55, 57, 59, 61, 63, 65, 66, 68, 70, 72, 74, 76, 78, 80, 82, 84.

$c_2 = \beta_2 \oplus [\Sigma_j\, b_j]_{mod2}$

j = 9, 11, 12, 14, 15, 18, 19, 21, 22, 25, 26, 29, 30, 33, 34, 36, 37, 40, 41, 44, 45, 48, 49, 52, 53, 56, 57, 60, 61, 64, 65, 66, 67, 68, 71, 72, 75, 76, 79, 80, 83, 84.

$c_3 = \beta_3 \oplus [\Sigma_k\, b_k]_{mod2}$

k = 10, 11, 12, 16, 17, 18, 19, 23, 24, 25, 26, 31, 32, 33, 34, 38, 39, 40, 41, 46, 47, 48, 49, 54, 55, 56, 57, 62, 63, 64, 65, 69, 70, 71, 72, 77, 78, 79, 80, 85.

$c_4 = \beta_4 \oplus [\Sigma_l\, b_l]_{mod2}$

l = 13, 14, 15, 16, 17, 18, 19, 27, 28, 29, 30, 31, 32, 33, 34, 42, 43, 44, 45, 46, 47, 48, 49, 58, 59, 60, 61, 62, 63, 64, 65, 73, 74, 75, 76, 77, 78, 79, 80.

$c_5 = \beta_5 \oplus [\Sigma_m\, b_m]_{mod2}$

m = 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 81, 82, 83, 84, 85.

$c_6 = \beta_6 \oplus [\Sigma_n\, b_n]_{mod2}$

n = 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65.

$c_7 = \beta_7 \oplus [\Sigma_p\, b_p]_{mod2}$

p = 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85.

$c_\Sigma = [\Sigma\, \beta_q]_{mod2} \oplus [\Sigma\, b_r]_{mod2}$

q = 1, 2, 3, 4, 5, 5, 7, 8

r = 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85.

3.2.2.1 *Paritás ellenőrző algoritmus az adat hitelesítéshez.* A B-22. táblázatban bemutatott és a következőkben részletezett algoritmus használatos a jelsorozaton belül egy 1 bites hiba észlelésére és kijavítására, és 2, vagy több bit hiba észlelésére a jelsorozaton belül.

3.2.2.1.1 Minden egyes jelsorozat 85 adat bitet foglal magába, ahol a 77 Legnagyobb Helyértékű Bitek az adat chipek ($b_{85}, b_{84}, \dots, b_{10}, b_9$) és a 8 Legkisebb Helyértékű Bit a Hamming kód ellenőrző bitek 4 hosszban ($\beta_8, \beta_7, \dots \beta_2, \beta_1$).

3.2.2.1.2 Az 1 bites hibáknak a jelsorozaton belüli kijavításához a következő ellenőrző összegek kerülnek összeállításra: (c_1, c_2, … , c_7), és a 2 bites hibáknak az észleléséhez (vagy több-páros-szám-bit hibákhoz) egy c_Σ ellenőrző összeg kerül generálásra, ahogy az a B-22. táblázatban bemutatásra kerül. Az egyedi hibák kijavítására és a többszörös hibák észlelésére a következők használatosak:

a) Egy jelsorozat akkor tekintett helyesnek, ha az összes ellenőrző összeg (checksum) (c_1, … , c_7 és c_Σ) “0”-val egyenlő, vagy ha csak az ellenőrző összegek egyike (c_1, … , c_7) egyenlő “1”-el és a c_Σ egyenlő “1”-el.

b) Ha az ellenőrző összegekből (c_1, … , c_7) kettő, vagy több “1”-el egyenlő, és a c_Σ is “1”-el egyenlő, akkor a “b_{icor}” karakter ellentétes karakterre kerül helyesbítésre a következő bit helyzetekben:

“i_{cor}” = $c_7c_6c_5c_4c_3c_2c_1 + 8 – K$, feltéve, hogy “$i_{cor}$” Ł 85,

ahol: “$c_7c_6c_5c_4c_3c_2c_1$” az ellenőrző összegekből (c_1, … , c_7) összeállított bináris szám, úgy, hogy a c_1 a Legkisebb Helyértékű Bit /LSB/ és a c_7 a Legnagyobb Helyértékű Bit /MSB/. A ’K’ a legnagyobb helyértékű ellenőrző összeg sorszáma nem egyenlő “0”-val.

Ha az icor > 85, akkor egy páratlan számú többszörös hiba van, és az adat visszautasításra kerül.

c) Ha az ellenőrző összegekből (c_1, … , c_7) legalább egy egyenlő “1”-el és a c_Σ egyenlő “0”-val, vagy ha az összes ellenőrző összeg (c_1, … , c_7) egyenlő “0”-val, de a c_Σ egyenlő “1”-el, akkor többszörös hiba van, és az adat visszautasításra kerül.

3.2.2.2 *Műhold óra helyesbítő paraméterek*

3.2.2.2.1 A GLONASS rendszer ideje a következők szerint van meghatározva:

$$t_{GLONASS} = t_k + \tau_n(t_b) - \gamma_n(t_b)\,(t_k - t_b)$$

ahol a t_k, $\tau_n(t_b)$, $\gamma_n(t_b)$ a 3.2.1.3.1 pontban leírt paraméterek.

3.2.2.2.2 A GLONASS ideje az Orosz Nemzeti Idő Szolgálat (UTC(SU)) idejére van vonatkoztatva az alábbiak szerint:

$$t_{UTC(SU)} = t_{GLONASS} + \tau_c - 03 \text{ óra } 00 \text{ perc}$$

ahol:
τ_c egy, a 3.2.1.3.4 pontban leírt paraméter, és
03 óra 00 perc egy folyamatos idő eltolás a Moszkva-i és a Greenwich-i idő közötti különbség miatt.

3.2.2.3 *Műhold helyzet*

3.2.2.3.1 A pillanatnyi műhold helyzet a GLONASS navigációból az efemerisz paraméterek felhasználásával kerül meghatározásra, ahogy az a B-17. táblázatban megadásra kerül.

3.2.2.3.2 Az efemerisznek a pillanatnyi ideje a t_b-ből a ($|\tau_i| = |t_i - t_b| \leq 15$ perc) időtartamon belül a pillanatnyi idejű t_i-re történő átszámítása a műholdak mozgását leíró differenciál-egyenletekből a numerikus integrálási technikát felhasználva kerül végrehajtásra. Ezeknek az egyenleteknek a jobb oldali részén a gyorsulások, a μ tömegvonzási állandó és a J^2_0 geopotenciál második zónális harmonikusa - amely a föld sarki lapultságát határozza meg - felhasználásával kerülnek meghatározásra és a luni-szoláris zavaró hatás miatti gyorsulások is számításba vételre kerülnek. Az egyenletek a PZ-90 (3.2.5) koordináta rendszerbe vannak integrálva a negyedrendű Runge-Kutta technika alkalmazásával, az alábbiakban bemutatottak szerint:

$$\frac{dx}{dt} = Vx$$

$$\frac{dy}{dt} = Vy$$

$$\frac{dz}{dt} = Vz$$

$$\frac{dV_x}{dt} = -\frac{\mu}{r^3}\ x - \frac{3}{2}\ J_0^2\ \frac{\mu a_e^2}{r^5}\ x\left(1 - \frac{5z^2}{r^2}\right) + \omega^2 x + 2\omega V_y + \ddot{x}$$

$$\frac{dV_y}{dt} = -\frac{\mu}{r^3}\ y - \frac{3}{2}\ J_0^2\ \frac{\mu a_e^2}{r^5}\ y\left(1 - \frac{5z^2}{r^2}\right) + \omega^2 y + 2\omega V_x + \ddot{y}$$

$$\frac{dV_z}{dt} = -\frac{\mu}{r^3}\ z - \frac{3}{2}\ J_0^2\ \frac{\mu a_e^2}{r^5}\ z\left(1 - \frac{5z^2}{r^2}\right) + \ddot{z}$$

Ahol,

$$r = \sqrt{x^2 + y^2 + z^2}\ ;$$

μ = a föld általános tömegvonzási állandó (398 600,44 × 10^9 m^3/s^2);
a_e = a nagy fél-tengely (6 378 136 m);
$J^2{}_0$ = a geopotenciál második zónás harmonikusa (1 082 625,7 × 10^{-9}); és
ω = a föld forgási sebessége (7,292115 × 10^{-5} radián/s).

Az $x_n(t_b)$, $y_n(t_b)$, $z_n(t_b)$ koordináták és a sebesség-vektor összetevők

$\dot{x}_n(t_b) = V_x$,

$\dot{y}_n(t_b) = V_y$,

$\dot{z}_n(t_b) = V_z$ az integrálás kezdeti feltételei. A luni-szoláris zavaró hatás miatti gyorsulások , az

$\ddot{x}_n(t_b)$ $\ddot{y}_n(t_b)$ $\ddot{z}_n(t_b)$ meghatározások, állandók az integrálási intervallumban, ± 15 perc.

3.2.3 LÉGIJÁRMŰ FEDÉLZETI ALKOTÓELEMEK

3.2.3.1 *GNSS (GLONASS) vevő*

3.2.3.1.1 *Műhold kizárás*. A vevőnek ki kell zárni minden olyan műholdat, amely nem megfelelő működési állapotúként van kijelölve a Globális Navigációs Műhold Rendszer /GLONASS/ navigációs közleményében.

3.2.3.1.2 *Műhold követés*. A vevőnek biztosítania kell azt a képességet, hogy folyamatosan nyomon kövessen minimum négy műholdat, és létre kell hoznia az azok mérésén alapulóan egy helymeghatározási megoldást.

3.2.3.1.3 *Doppler eltolódás*. A vevőnek képesnek kell lenni arra, hogy a dinamikus Doppler eltolódás hatását kiegyenlítse a névleges GLONASS jel vivőhullám fázisán és a szabvány kód méréseknél. A vevőnek ki kell egyenlíteni azt a Doppler eltolódást, ami a várt alkalmazáshoz egyértelműen hozzátartozik.

3.2.3.1.4 *Interferencia ellenállóság*. A vevőnek ki kell elégítenie a 3.7 pontban meghatározott interferencia ellenállósági követelményeket.

3.2.3.1.4.1 *Rendszeren belüli interferencia*. Amikor egy navigációs jel a k = n frekvencia csatornával vételre kerül, akkor a k = n - 1 vagy a k = n + 1 frekvencia csatorna számú navigációs jelek által létrehozott interferencia nem lehet több -48 dBc-nél a földfelszínen meghatározott minimális műhold teljesítményre vonatkozóan, feltéve, hogy az ezeket a jeleket sugárzó műholdak egyidejűleg a felhasználó általi láthatósági zónában helyezkednek el.

Megjegyzés. – A rendszeren belüli interferencia a távolság meghatározó ál-véletlen jel kereszt-korrelációs tulajdonsága a frekvencia osztásos többszörös hozzáférésű rendszert illetően.

3.2.3.1.5 *Az óra és efemerisz adatok alkalmazása*. A vevőnek biztosítania kell azt, hogy csak a pontos efemerisz és óra adatokat használja fel, mielőtt bármilyen helymeghatározási megoldást adna.

3.2.3.1.6 *Szökő-másodperc helyesbítés*. A GLONASS idő szökő-másodperc helyesbítéséhez (lásd a 3.2.1.3.1, tb-t) a GLONASS vevőnek képesnek kell lenni arra, hogy:

a) Összeállítson egy szűrt és érvényes pszeudo-távolság mérés sorozatot; és

b) Újraszinkronizálja az adat jelsorozat idő jelét a jelkövetés elvesztése nélkül.

3.2.3.1.6.1 A GLONASS idő szökő-másodperc helyesbítés után a GLONASS vevőnek az Egyeztetett Világidőt /UTC/ a következők szerint kell felhasználni:

a) Felhasználni az 'öreg' (a helyesbítést megelőző) Egyeztetett Világidő /UTC/ időt az öreg efemerisz adatokkal együtt (a 00 óra 00 perc 00 másodperc UTC előtt továbbított adatok); és

b) Felhasználni a felfrissített Egyeztetett Világidőt /UTC/ az új efemerisz adatokkal együtt (a 00 óra 00 perc 00 másodperc UTC után továbbított adatok).
3.2.4 IDŐ

3.2.4.1 A GLONASS-M műholdaknál a navigációs közleménynek magába kell foglalnia azokat az adatokat, amelyek az UTC(SU) időnek az UT1-re való vonatkoztatásához szükségesek. A GLONASS idejét az UTC(SU) időhöz viszonyítva 1 milliszekundumon belül kell tartani az órák egész száma helyesbítése után a GLONASS vezérlő szegmens speciális jellemzői miatt:

$$| t_{GLONASS} - (UTC + 03 \text{ óra } 00 \text{ perc}) | < 1 \text{ ms}$$

A navigációs adatnak magába kell foglalnia azt a követelmény adatot, amely a GLONASS idejét az UTC időre (az Orosz Nemzeti Idő Szolgálat által kezelt idő, UTC (SU)) 1 mikroszekundumon belül vonatkoztatja.

1. Megjegyzés. – A GLONASS műholdak idő-léptéke időszakosan összehasonlításra kerül a központi szinkronizált idővel. A GLONASS műholdak idő-léptékének helyesbítései – a GLONASS időnek és az UTC(SU) időnek az összehasonlítása – a GLONASS föld-bázisú vezérlő komplexumokon kerülnek kiszámításra és naponta kétszer áttöltésre kerülnek a műholdakba.

2. Megjegyzés. – Nincs egészszámú másodperc különbség a GLONASS ideje és az UTC idő között. A GLONASS idő-léptéke időszakosan egészszámú másodpercekre helyesbítésre kerül az UTC *helyesbítésekkel egyidejűleg, ami a Nemzetközi Idő Hivatal /Bureau International de l'Heure/ közleménye (szökő-másodperc helyesbítés) szerint kerül végrehajtásra. Ezek a helyesbítések 00 óra 00 perc 00 másodperc UTC időben éjfélkor kerülnek végrehajtásra, az év negyedéveinek végén. A GLONASS szökő-másodperc helyesbítésnél a navigációs közleményen belüli idő-jel úgy változtatja a helyzetét (egy folyamatos idő-léptékben), hogy 2-másodperces 'korszakkal' szinkronizálttá váljon a helyesbített UTC idő-léptékhez. A GLONASS felhasználói előzetes értesítést kapnak ezekről a tervezett helyesbítésekről. A GLONASS-M műholdakra az ezekről a helyesbítésekről való előzetes értesítés a felhasználó részére a KP navigációs közlemény paraméteren keresztül kerül biztosításra.*

3.2.4.2 A közös műhold idő-lépték szinkronizáció pontosságnak 20 nanoszekundumnak kell lenni (1 szigma) a GLONASS műholdakra és 8 nano-szekundumnak (1 szigma) a GLONASS-M műholdakra.

3.2.4.3 A GPS időhöz történő helyesbítés a GLONASS időre vonatkozóan (vagy a két idő-lépték közötti különbség), amelyet a GLONASS-M műholdak sugároznak, a t_{GPS}, nem haladhatja meg a 30 nanoszekundumot (1 szigma).

Megjegyzés. – A t_{GPS} (30 ns) pontossága a GPS Szabvány Helymeghatározási Szolgáltatás /SPS/ torzított /durva/ hozzáférési jelére vonatkoztatva kerül meghatározásra, és ki lehet számítani a GLONASS-M műholdakat felhasználó GLONASS rendszer vizsgálatainak befejeztével.

3.2.5 KOORDINÁTA RENDSZER

3.2.5.1 *PZ-90 (a Föld közös szárazföldi ellipszoid és gravitációs tér paraméterei 1990.).* A GLONASS által sugárzott efemerisznek egy adott műhold adattovábbító antennája fázis középpontjának a helyzetét a PZ-90 föld-középpontú föld-állandójú vonatkoztatási rendszerben kell leírni.

3.2.5.2 *A PZ-90 és a WGS-84 közötti átszámítás*. A következő átszámítási paramétereket kell felhasználni a PZ-90 helyzet koordinátákról a WGS-84 koordináta helyzet megkapásához:

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix}_{WGS-84} = \begin{bmatrix} -1.1 \\ -0.3 \\ -0.9 \end{bmatrix} + (1 - 0.12 \times 10^{-6}) \begin{bmatrix} 1 & -0.82 \times 10^{-6} & 0 \\ +0.82 \times 10^{-6} & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}_{PZ-90}$$

Megjegyzés. – Az X, Y és Z méter-ben van kifejezve.

3.2.5.2.1 Az átszámítási hiba nem haladhatja meg az 1,5 métert (1 szigma) az egyes koordináta tengelyek mentén.

3.3 A GPS és a GLONASS kombinált felhasználása

3.3.1 LÉGIJÁRMŰ FEDÉLZETI ALKOTÓELEMEK

3.3.1.1 *Kombinált Globális Navigációs Műhold Rendszer /GNSS/ vevő*. A kombinált GNSS vevőnek fel kell dolgozni a GPS-től és a GLONASS-tól jövő jeleket a 3.1.3.1 pontban, a GPS (GNSS) vevőre meghatározott követelményeknek, valamint a 3.2.3.1 pontban a GLONASS vevőre meghatározott követelményeknek megfelelően.

3.3.1.1.1 *Interferencia ellenállóság*. A kombinált GNSS vevőnek ki kell elégíteni a GPS-re és a GLONASS-ra vonatkozó, a 3.7 pontban meghatározott egyedi követelményeket.

3.3.1.2 *Antenna/k/.* A GPS és a GLONASS jeleit egy, vagy több antennán keresztül kell venni.

Megjegyzés. – A GNSS vevő antenna teljesítmény jellemzői a 3.8 pontban kerültek meghatározásra.

3.3.1.3 *A koordináta rendszerek közötti átszámítás*. Az egy kombinált GPS és GLONASS vevő által biztosított helyzet információt WGS-84 földi koordinátákban kell kifejezni. A GLONASS műhold helyzetet, amely a PZ-90 koordináta rendszerben kapható meg, át kell alakítani a WGS-84 és a PZ-90 közötti különbség számításba vételével, ahogy az a 3.2.5.2 pontban meghatározásra került.

3.3.1.4 *GPS/GLONASS idő*. Amikor a GLONASS és a GPS méréseit összekapcsolják, akkor a GLONASS ideje és a GPS ideje közötti különbséget számításba kell venni.

3.4 Légijármű-bázisú kiegészítő rendszer (ABAS)

Megjegyzés. – A Légijármű bázisú kiegészítő rendszer /ABAS/ útmutató anyaga a “D”- Melléklet 5. részében került megdásra.

3.5 Műhold-bázisú kiegészítő rendszer (SBAS)

3.5.1 ÁLTALÁNOS RÉSZ

Megjegyzés. – Az ebben a részben lévő paraméterek WGS-84-ben vannak meghatározva.

3.5.2 RÁDIÓFREKVENCIÁS (RF) JELLEMZŐK

3.5.2.1 *Vivőhullám frekvencia stabilitás*. A vivőhullám frekvencia rövidtávú stabilitásának (az Allan Variancia négyzetgyöke) a műhold adó antenna kimeneténél jobbnak kell lenni 5×10^{-11}-nél az 1.-től a 10. másodpercig.

3.5.2.2 *Vivőhullám fázis zaj*. A modulálatlan vivőhullám fázis zajának spektrális sűrűségének olyannak kell lennie, hogy egy fázisszabályzó hurok 10 Hz-es egy-oldalas zajszűrővel képes legyen a vivőhullám követésére egy 0,1 radiános (1 szigma) pontossággal.

3.5.2.3 *Hamis sugárzás*. A hamis sugárzásnak legalább 40 dB-el a modulálatlan vivőhullám teljesítmény alatt kell lenni az összes frekvencián.

3.5.2.4 *Kód/vivőhullám frekvencia összefüggés*. A rövidtávú (10 másodpercnél kevesebb) viszonylagos frekvencia különbség a kód fázis sebesség és a vivőhullám frekvencia között kevesebb kell, hogy legyen 5×10^{-11}-nél (szabvány eltérés). A hosszú távon (100 másodpercnél kevesebb) az adás kód fázisának változása, a vivőhullám ciklusa a kód chipeknek az 1540-el való megszorzásával átszámítva, és az adás vivőhullám fázisának a ciklusokban való változása között a különbségnek egy vivőhullám cikluson belül kell lenni (szabvány eltérés).

Megjegyzés. – Ez a műhold adó antennájának kimenetére alkalmazandó, és nem foglalja magába a lefelé menő terjedés útján lévő ionoszférikus törés miatti kód/vivőhullám eltérést.

3.5.2.5 *Korrelációs veszteség*. A visszanyert jel teljesítményében a jel moduláció hiányossága és a hullámforma torzítás miatti veszteség nem haladhatja meg az 1 dB-t.

Megjegyzés. – A jel-teljesítmény veszteség az egy 2,046 MHz-es sávszélességben kisugárzott teljesítmény és az egy zajmentes veszteségmentes 1-chip korrelációs térközű és egy 2,046 MHz-es sávszélességű vevővel visszanyert jel-teljesítmény közötti különbség.

3.5.2.6 *Maximális kód fázis eltérés*. A közvetítő jel maximális nem-helyesbített kód fázis nem térhet el az egyenértékű Műhold Bázisú Kiegészítő Rendszer /SBAS/ hálózat idejétől (SNT) $\pm 2^{-20}$ másodpercnél többel.

3.5.2.7 *Kód/adat összefüggés*. Minden egyes 2 milliszekundumos jelnek szinkronban kell lenni minden egyes más kód 'korszakkal'.

3.5.2.8 *Közlemény szinkronizálás*. Annak az első jelnek a felfutó élét, amely a pillanatnyi közlemény első bitjétől függ, kell a Műhold Bázisú Kiegészítő Rendszerből a Műhold Hálózat Idő egy 1-másodperces 'korszakával' szinkronizáltan sugározni.

3.5.2.9 *Konvolúciós kódolás*. A 250 bit/másodperces adatfolyamot 2 jel/bit arányban kell kódolni egy konvolúciós kód alkalmazásával, hogy a korlátozott 7-es hossz 500 jel/másodperc-et eredményezzen. A konvolúciós kódolás logikai elrendezésének olyannak kell lenni, ahogy azt a B-11. ábra bemutatja, úgy, hogy a G3 kimenet került kiválasztásra az egyes 4 milliszekundumos adat bit periódusok első felére.

3.5.2.10 *Ál-véletlen zaj (PRN) kódok*. Az egyes ál-véletlen zaj /PRN/ kódoknak egy 1023 bit-es Gold kódnak kell lenni, amely önmaga is a Modulo-2-es összeadása két 1023 bites lineáris alakzatnak, a G1 és $G2_i$-nek. A $G2_i$ jelsorozatot a G2 jelsorozatnak a hozzá kapcsolt egész számú chipekkel történő késleltetésével kell létrehozni, ahogy azt a B-23. táblázat bemutatja. A G1 és G2 jelsorozatok mindegyikét úgy kell meghatározni, mint egy 10-fokozatú léptető regiszter 10. fokozatának kimenetét, ahol a léptető regiszter bemenete a Modulo-2 összeadása a léptető regiszter következő fokozatának:

a) G1: 3. és 10. fokozatok; és

b) G2: 2., 3., 6., 8., 9. és 10. fokozatok.

A G1 és G2 léptető regiszterek kezdő helyzetének "1111111111"-nek kell lenni.

B-23. táblázat: A Műhold Bázisú Kiegészítő Rendszer /SBAS/ ál-véletlen zaj /PRN/ kódjai

PRN kód szám	G2 késleltetés (chipek)	Az első 10 SBAS chip (A balról a legelső bit képviseli az először továbbított chipet, bináris)
120	145	110111001
121	175	101011110
122	52	1101001000
123	21	1101100101

3.5.3 ADAT SZERKEZET

3.5.3.1 *Formátum összegzés*. Az összes közleménynek magába kell foglalni egy közlemény típus azonosítót, egy bevezető jelsorozatot, az adatmezőt és a ciklikus redundancia ellenőrzést (CRC), ahogy azt a B-12. ábra bemutatja.

3.5.3.2 *Bevezető jelsorozat, előtag*. A bevezető jelsorozatnak a következő bit-sorozatból kell állni: “01010011 10011010 11000110”, három egymást követő blokkba felosztva. Minden más 24 bites bevezető jelsorozat kezdetének szinkronban kell lenni egy 6 másodperces GPS al-keret ’korszakkal’.

3.5.3.3 *Közlemény típus azonosító*. A közlemény típus azonosítónak egy, a közlemény típusát azonosító 6 bites értéknek kell lenni (a 0.tól a 63.-ig terjedő típusok), ahogy az a B-24. táblázatban meghatározásra került. A közlemény típus azonosítóval először a Legnagyobb Helyértékű Bitet kell továbbítani.

3.5.3.4 *Adatmező*. Az adatmező 212 bit kell, hogy legyen úgy, ahogy az a 3.5.6 pontban meghatározásra került. Az egyes adatmező paramétereknél először a Legnagyobb Helyértékű Bitet kell továbbítani.

3.5.3.5 *Ciklikus Redundancia Ellenőrzés (CRC)*. A Műhold Bázisú Kiegészítő Rendszer közlemény Ciklikus Redundancia Ellenőrző kódját a 3.9 pontban megadottaknak megfelelően kell kiszámolni.

3.5.3.5.1 A CRC kód hosszának k = 24 bitnek kell lenni.

3.5.3.5.2 A CRC alkotó polinomja a következő kell, hogy legyen:

$$(x) = x^{24} + x^{23} + x^{18} + x^{17} + x^{14} + x^{11} + x^{10} + x^{7} + x^{6} + x^{5} + x^{4} + x^{3} + x + 1$$

B-24. táblázat: Kisugárzott közlemény típusok

Közlemény típus	Tartalom
0	"Ne használják" (SBAS ellenőrzés mód)
1	Ál-véletlen zaj /PRN/ maszk
2-től 5-ig	Gyors helyesbítés
6	Integritás /teljesség/ információ
7	Gyors helyesbítés teljesítőképesség-csökkenési tényező
8	Tartalék
9	Geostacionárius pálya /GEO/ távolság meghatározási paraméterek
10	Teljesítőképesség-csökkenési paraméterek
11	Tartalék
12	Műhold Bázisú Kiegészítő Rendszer /SBAS/ hálózati idő/Egyeztetett Világ-idő /UTC/ eltolódási paraméterek
13-tól 16-ig	Tartalék
17	Geostacionárius pályájú műhold naptár
18	Ionoszférikus rácspont maszkok
19-től 23-ig	Tartalék
24	Kevert gyors/hosszú-távú műhold hiba helyesbítések
25	Hosszú-távú műhold hiba helyesbítések
26	Ionoszférikus késés helyesbítések
27	Műhold Bázisú Kiegészítő Rendszer üzemi közlemény
28	Óra-efemerisz kovariancia mátrix
29-től 61-ig	Tartalék
62	Fenntartott
63	Nulla közlemény

3.5.3.5.3 A Ciklikus Redundancia Ellenőrzés információs mezőjének, M(x), a következőnek kell lenni:

$$M(x) = \sum_{i-1}^{226} m_i x^{226-i} = m_1 x^{225} + m_2 x^{224} + \ldots + m_{226} x^0$$

3.5.3.5.4 Az M(x)-t a 8-bites SBAS közlemény bevezető jelszakaszából, a 6-bites közlemény típus azonosítóból és a 212 bites adatmezőből kell kialakítani. A biteket olyan sorrendben kell elrendezni és a Műhold Bázisú Kiegészítő Rendszerű műholdról továbbítani, hogy az m_1 feleljen meg a bevezető jelszakasz első továbbított bitje és az m_{226} feleljen meg az adatmező 212 bitjének.

3.5.3.5.5 A Ciklikus Redundancia Ellenőrzés kód r-bitjeit úgy kell sorrendbe rakni, hogy az r_1 legyen az első sugárzott bit és az r_{24} az utolsó sugárzott bit.

3.5.4 ADATTARTALOM

3.5.4.1 *Ál-véletlen zaj /PRN/ maszk paraméterek.* A PRN maszk paramétereknek a következőknek kell lenni:

PRN kód szám: egy szám, amely egyértelműen azonosítja a műhold PRN kódját és a hozzá kapcsolódó kijelölést, ahogy azt a B-25. táblázat bemutatja.

PRN maszk: 210 PRN maszk érték, ami megfelel a műhold PRN kód számainak. A maszknak a 210 PRN maszk értékből 51-nek kell lenni.

Megjegyzés. – A PRN maszk első továbbított bitje megfelel az 1. számú PRN kódnak.

B-25. táblázat: Ál-véletlen zaj /PRN/ kód szám kijelölés

PRN kód szám	Kijelölés
1 – 37	Globális Helymeghatározó Rendszer /GPS/
38 – 61	GLONASS résszám plusz 37
62 – 119	Tartalék
120 – 138	Műhold Bázisú Kiegészítő Rendszer /SBAS/
139 – 210	Tartalék

PRN maszk érték: egy bit PRN maszkban, ami azt jelzi, hogy az adat tartalmazza-e a kapcsolódó műhold PRN kód számát (1.-től 210.-ig).

Kódolás: 0 = az adat nem tartalmazza
1 = az adat tartalmazza

PRN maszk szám: a PRN maszkban beállított maszk értékek sorszáma (1.-től 51.-ig).

Megjegyzés. – A PRN maszk szám "1" arra a legalacsonyabb műhold PRN számra vonatkozik, amelyre a PRN maszk érték "1".

Adat kibocsátás – Ál-véletlen zaj /PRN/ (IODP): egy jelzés, ami összekapcsolja a helyesbítési adatokat a PRN maszkkal.

Megjegyzés. – A paraméterek a következő közleményekben kerülnek leadásra:

a) PRN maszk (210 PRN maszk értékből áll) az 1. típusú közleményben;

b) PRN maszk szám a 24., 25. és 28. típusú közleményekben;

c) PRN kód szám: a 17. típusú közleményben; és

d) Adat kibocsátás – Ál-véletlen zaj /IODP/ az 1.-től az 5.-ig, a 7., és 25. típusú közleményekben.

3.5.4.2 *Geostacionárius pálya (GEO) távolság meghatározási paraméterek.* A Geostacionárius pálya (GEO) távolság meghatározási paramétereknek a következőknek kell lenni:
$t_{0,GEO}$: a GEO távolság meghatározási funkció referencia ideje, az adott nap éjfélje utáni időként kifejezve.

$[X_G Y_G Z_G]$: A GEO helyzet a $t_{0,GEO}$ időpontban.

$\left[\dot{X}_G \; \dot{Y}_G \; \dot{Z}_G\right]$: a GEO sebessége a $t_{0,GEO}$ időpontban.

$\left[\ddot{X}_G \; \ddot{Y}_G \; \ddot{Z}_G\right]$: a GEO gyorsulása a $t_{0,GEO}$ időpontban.

a_{Gf0}: a GEO óra idő eltolódása a Műhold Hálózati Időre /SNT/ vonatkozóan, a $t_{0,GEO}$ időpontban meghatározva.

a_{Gf1}: a GEO óra eltolódási sebessége a Műhold Hálózati Időre /SNT/ vonatkozóan.

Felhasználói távolság pontosság (URA): a távolságmérési pontosság négyzetes középértékének jelzése az atmoszférikus hatást is beleértve, ahogy az a B-26. táblázatban leírásra került.

Megjegyzés. – Az összes paraméter a 9. típusú közleményben kerül leadásra.

B-26. táblázat: Felhasználói távolság pontosság /URA/

URA	Pontosság (rms)
0	2 m
1	2,8 m
2	4 m
3	5,7 m
4	8 m
5	11,3 m
6	16 m
7	32 m
8	64 m
9	128 m
10	256 m
11	512 m
12	1 024 m
13	2 048 m
14	4 096 m
15	“Ne használják”

3.5.4.*3 Geostacionárius pálya /GEO/ naptár paraméterek.* A Geostacionárius pálya /GEO/ naptár paramétereknek a következőknek kell lenni:

Ál-véletlen zaj /PRN/ kód szám: lásd a 3.5.4.1 pontot.
Működési állapot és helyzet: A Műhold Bázisú Kiegészítő Rendszer /SBAS/ által biztosított funkciók jelzése. A szolgáltatás biztosítók azonosítóit a B-27. táblázat mutatja be.

Kódolás:	Bit 0. (LSB)	Távolság meghatározás	Be (0)	Ki (1)
	Bit 1.	Precíziós helyesbítések	Be (0)	Ki (1)
	Bit 2.	Műhold helyzet és alap helyesbítések	Be (0)	Ki (1)
	Bit 3.	Tartalék		
	Bit 4.-től 7.-ig	A szolgáltatás biztosító azonosítója		

Megjegyzés. – A 14-es szolgáltatás biztosító azonosító a Földi Bázisú Kiegészítő Rendszerhez /GBAS/ használatos és az SBAS-re nem alkalmazható.

$\left[X_{G,A}\ Y_{G,A}\ Z_{G,A}\right]$: a GEO helyzete a $t_{almanac}$ időpontban,

$\left[\dot{X}_{G,A}\ \dot{Y}_{G,A}\ \dot{Z}_{G,A}\right]$: a GEO sebessége a $t_{almanac}$ időpontban,

$t_{almanac}$: a GEO naptár adat referencia ideje az adott nap éjfélje utáni időként kifejezve.

Megjegyzés. – Az összes paraméter 17. típusú közleményben kerül leadásra.

3.5.4.4 *Műhold helyesbítési kisugárzó paraméterek*

3.5.4.4.1 A hosszútávú helyesbítési paramétereknek a következőknek kell lenni:

Adat kibocsátás (IOD_i): egy jelzés, amely összekapcsolja az i^{th} /i-ik/ műhold hosszútávú helyesbítéseit azokkal az efemerisz adatokkal, amelyeket az a műhold ad le.

1. Megjegyzés. – A Globális Helymeghatározó Rendszerre /GPS/ az Adat kibocsátás /IOD_i/ megfelel az Adat kibocsátás, Efemerisznek /IODE/ és az Adat kibocsátás, Óra /IODC/ 8 Legkisebb helyértékű bitjeinek /LSB-k/ (3.1.1.3.1.4 és 3.1.1.3.2.2).

2. Megjegyzés. – A GLONASS-ra az Adat kibocsátás /IOD_i/ azt az időtartamot jelzi, amikor a GLONASS adatokat a Műhold Bázisú Kiegészítő Rendszer /SBAS/ adatokkal együtt kell használni. Ez két mezőből áll, ahogy azt a B-28. táblázat bemutatja.

δx_i : az i műholdra, efemerisz helyesbítés az x-tengelyre.

δy_i : az i műholdra, efemerisz helyesbítés az y-tengelyre.

δz_i : az i műholdra, efemerisz helyesbítés a z-tengelyre.

$\delta a_{i,f0}$: az i műholdra, efemerisz idő helyesbítés.

$\delta \dot{x}_i$: az i műholdra, efemerisz sebesség helyesbítés az x-tengelyre.

$\delta \dot{y}_i$: az i műholdra, efemerisz sebesség helyesbítés az y-tengelyre.

$\delta \dot{z}_i$: az i műholdra, efemerisz sebesség helyesbítés a z-tengelyre.

$\delta a_{i,f1}$: az i műholdra az efemerisz idő helyesbítés változási sebessége.

$t_{i,LT}$: A δx_i, δy_i, δz_i, $\delta a_{i,f0}$, $\delta \dot{x}_i$, $\delta \dot{y}_i$, $\delta \dot{z}_i$ és a $\delta a_{i,f1}$ paraméterek alkalmazhatósági ideje, az adott nap éjfélje után eltelt másodpercekben kifejezve.

Sebesség kód: az üzenet formátum leadásának a jelzése (B-48. táblázat és B-49. táblázat).

Kódolás: 0 = $\delta \dot{x}_i$ $\delta \dot{y}_i$ $\delta \dot{z}_i$ $\delta a_{i,f1}$ és nincs leadva.

1 = $\delta \dot{x}_i$ $\delta \dot{y}_i$ $\delta \dot{z}_i$ $\delta a_{i,f1}$ és le van adva.

Megjegyzés. – Az összes paraméter a 24. és 25. típusú közleményben kerül leadásra.

B-27. táblázat: A Műhold Bázisú Kiegészítő Rendszer /SBAS/ szolgáltatás biztosítóinak azonosítói

Azonosító	Szolgáltatás biztosító
0.	WAAS
1.	EGNOS
2.	MSAS
3.-tól 13.-ig	Tartalék
14., 15.	Fenntartva

B-28. táblázat: Adat kibocsátás /IOD$_i$/ a GLONASS műholdakra

Legnagyobb helyiértékű bit /MSB/	Legkisebb helyiértékű bit /LSB/
Érvényességi időköz (5 bit)	Várakozási idő (3 bit)

3.5.4.4.2 A gyors helyesbítési paramétereknek a következőknek kell lenni:

Gyors helyesbítés (FC$_i$): az i műholdra, a gyorsan változó hibák pszeudo-távolság helyesbítése más, mint a troposzférikus és ionoszférikus hiba, a pszeudo-távolsághoz a hosszútávú helyesbítéseknél való felhasználás után kerül hozzáadásra.

Megjegyzés. – A felhasználó vevője független troposzférikus helyesbítéseket használ fel (3.5.8.4.2 és 3.5.8.4.3).

Gyors helyesbítés típus azonosító: Egy jelzés (0, 1, 2, 3) arról, hogy a 24. típusú közlemény tartalmazza-e az ál-véletlen zaj /PRN/ maszkhoz kapcsolt gyors helyesbítés és sértetlenség /integritás/ adatot a 2.típusú, 3. típusú, 4. típusú, vagy 5. típusú közleményekből, külön-külön.

Adat kibocsátás – Gyors helyesbítés (IODF$_j$): Egy jelzés, ami összekapcsolja a Felhasználói Differenciál Távolságmérési Hibákat /UDREI$_i$/ a gyors helyesbítésekkel. A *j* indexnek azt a közlemény típust (j = 2.-től 5.-ig) kell jelezni, amelyre az Adat kibocsátás – Gyors helyesbítés (IODF$_j$)-t alkalmazza (a gyors helyesbítés típus azonosító +2).

Megjegyzés. – A gyors helyesbítés típus azonosító a 24. típusú közleményben van leadva. A Gyors Helyesbítés /FC_i/ a 2.-tól az 5.-ig típusú és a 24. típusú közleményekben van leadva. Az Adat kibocsátás – Gyors helyesbítés ($IODF_j$) a 2.-tól a 6.-ig típusú és a 24. típusú közleményekben kerül leadásra.

3.5.4.5 *A gyors és hosszútávú helyesbítések sértetlenségi paraméterei*. A gyors és hosszútávú helyesbítések sértetlenségi paramétereinek a következőknek kell lenni:

$UDREI_i$ /Felhasználói Differenciál Távolságmérési Hiba Jelzés$_i$/ : Egy jelzés, amely meghatározza a $\sigma^2_{i,UDRE}$ -t az i műholdra, ahogy az a B-29. táblázatban leírásra került.

Az óra és efemerisz megmaradó hibáinak négyzetes középérték modelje /$\sigma^2_{i,UDRE}$ /: Az i műhold felhasználói differenciál távolságmérési hibái normális eloszlásának négyzetes középértéke a gyors és hosszútávú helyesbítések alkalmazása után, az atmoszférikus hatások kizárásával és a vízszintes védelmi szint/függőleges védelmi szint számításoknál felhasználva (3.5.5.6).

Megjegyzés. – Az összes paraméter a 2.-tól 6.-ig típusú és a 24. típusú közleményekben kerül leadásra.

3.5.4.6 *Ionoszférikus helyesbítési paraméterek*. Az Ionoszférikus helyesbítési paramétereknek a következőknek kell lenni:
Ionoszférikus rácspont /IGP/ maszk: 11 ionoszférikus rácspont (IGP) sorozat sávjának maszkja, ahogy az a B-30. táblázatban meg van határozva.

B-29. táblázat: A Felhasználói Differenciál Távolságmérési Hibajelzés /UDREI$_i$/ kiértékelése

$UDREI_i$	$\sigma^2_{i,UDRE}$
0	0,0520 m^2
1	0,0924 m^2
2	0,1444 m^2
3	0,2830 m^2
4	0,4678 m^2
5	0,8315 m^2
6	1,2992 m^2
7	1,8708 m^2
8	2,5465 m^2
9	3,3260 m^2
10	5,1968 m^2
11	20,7870 m^2
12	230,9661 m^2
13	2 078,695 m^2
14	“Nem ellenőrzött”
15	“Ne használja”

Ionoszférikus rácspont /IGP/ sáv maszk: Az Ionoszférikus rácspont /IGP/ maszk értékek egy sorozata, amely megfelel a B-32. táblázatban meghatározott 11 Ionoszférikus rácspont /IGP/ sáv egyikében lévő összes Ionoszférikus rácspont /IGP/ helyzetnek.

Ionoszférikus rácspont /IGP/ maszk érték: egy bit, amely azt jelzi, hogy adat biztosításra kerül-e azon az ionoszférikus rácspont sávon belül a kapcsolódó ionoszférikus rácsponthoz.

Kódolás: 0 = adat nincs biztosítva.
1 = adat biztosítva van.

Ionoszférikus rácspont /IGP/ sáv szám: A leadásra kerülő Ionoszférikus rácspont /IGP/ sáv maszkok száma.

Ionoszférikus rácspont /IGP/ sáv azonosító: Az Ionoszférikus sávot a B-30. táblázatban meghatározottaknak megfelelően azonosító szám.

Ionoszférikus rácspont /IGP/ blokk azonosító: Az Ionoszférikus rácspont /IGP/ blokk azonosítója. Az Ionoszférikus rácspont /IGP/ blokkok 15 IGP csoportba osztva vannak meghatározva, egy IGP sáv maszkon belül az IGP-k sorrendje az, amelynek az IGP maszk értéke “1”. Az Ionoszférikus rácspont /IGP/ blokkok az IGP maszk érték továbbítás sorrendjében kerülnek számozásra, a “0”-val kezdődően.

Érvényességi időköz (V): Az az időköz, amelyre a GLONASS efemerisz adatok alkalmazhatóak (egy 30 s-os eltolással kódolva), ahogy az a B.-31. táblázatban leírásra került.

Várakozási idő (L): Az az időtartam, ami az utolsó GLONASS efermerisz adatnak a földi rész általi vételének időpontja és a GEO(t_{ltc})-nél /Geostacionárius pálya(idő/hosszútávú helyesbítés)/ a hosszútávú helyesbítési közlemény első bitjének továbbítási ideje között van, ahogy az a B-32. táblázatban leírásra került.

$IODI_k$ /Adat kibocsátás Ionoszférikus rácspont/: jelzés akkor, amikor a k-ik Ionoszférikus Rácspont /IGP/ sáv maszk változik.

IGP függőleges késés becslés: az 1575,42 MHz-es jelnél előidézett késés becslése akkor, ha az az ionoszférán az Ionoszférikus Rácspontnál /IGP/ függőlegesen eltérítődik.

Kódolás: Az "111111111" bit alakzat a "Ne használja"-t jelzi.

$GIVEI_i$ /Rácspont ionoszférikus függőleges hiba jelzés/: egy jelzés, amely a $\sigma^2_{i,GIVE}$ -t határozza meg úgy, ahogy az a B-33. táblázatban leírásra került.

A megmaradó ionoszférikus hibák négyzetes középérték modelje ($\sigma^2_{i,GIVE}$): a megmaradó ionoszférikus függőleges hibáknak az ionoszférikus rácspontnál lévő normál eloszlás négyzetes középeltérése az egy L1 jelre.

Megjegyzés. – Az összes paraméter 18. típusú és 26. típusú közleményekben kerül leadásra.

B-30. táblázat: Ionoszférikus rácspont /IGP/ helyzetek és sáv számok

3.5.4.7 *Teljesítőképesség csökkenési paraméterek.* A Teljesítőképesség csökkenési paraméterek, amikor használatosak, akkor a következőknek kell lenniük:

Gyors helyesbítési teljesítőképesség csökkenési tényező jelzés (ai_i): a gyors helyesbítési teljesítőképesség csökkenési tényezőnek (a_i) az i-ik műholdra vonatkozó jelzése, ahogy az a B-34. táblázatban leírásra került.

Megjegyzés. – Az ai_i még a gyors helyesbítések időhatár intervallumának meghatározására is használatos, ahogy az a 3.5.8.1.1 pontban leírásra került.

Rendszer várakozási idő (t_{lat}): a gyors helyesbítési teljesítőképesség csökkenés kezdete és a Felhasználói Differenciál Távolságmérési Hiba Jelzés /UDREI/ referencia ideje közötti időköz.

B_{rrc} : az a paraméter, amely korlátozza a zaj és kerekítési hibákat akkor, amikor a távolság meghatározási változás helyesbítés teljesítőképesség csökkenés számításra kerül a 3.5.5.6.2.2 pontban leírtak szerint.

C_{ltc_lsb}: a keringési pálya és az idő információk felbontóképessége miatti maximális kerekítési hiba.

C_{ltc_v1} : az idő és a keringési pálya sebesség különbségek miatt kihagyott közlemények maximális távolság meghatározási változás különbsége sebesség hiba korlátozása.
I_{ltc_v1} : a hosszútávú helyesbítések felfrissítési időköze, ha a sebességi kód = 1 (3.5.4.4.1).

C_{ltc_v0} : az a paraméter, amely két egymásra következő hosszútávú helyesbítés közötti különbséget határolja azokra a műholdakra, amelyeknek a sebesség kódja = 0.

I_{ltc_v0} : a hosszútávú közlemények minimális felfrissítési időköze, ha a sebességi kód = 0 (3.5.4.4.1).

C_{GEO_lsb} : a keringési pálya és az idő információk felbontóképessége miatti maximális kerekítési hiba.

C_{GEO_v} : az idő és a keringési pálya sebesség különbségek miatt kihagyott közlemények maximális távolság meghatározási változás különbsége sebesség hiba korlátozása.

I_{GEO} : a Geostacionárius pálya /GEO/ távolságmérési funkciós közleményeinek felfrissítési időköze.

B-34. táblázat: Gyors helyesbítési teljesítőképesség csökkenési tényező

13	3,30 mm/s^2
14	4,60 mm/s^2
15	5,80 mm/s^2

C_{er} : egy, a precíziós megközelítés / megközelítés – függőleges vezetés időzítésekhez felhasznált adatokon túli adatokhoz kapcsolódó megmaradó hiba korlátozása.

C_{iono_step} : az egymás után következő ionoszférikus rácspont késési értékei közötti különbség korlátozása.

I_{iono} : az ionoszférikus helyesbítési közlemények minimális felfrissítési időköze.

$C_{iono\ ramp}$ *:* az ionoszférikus helyesbítések változási sebessége.

RSS_{UDRE} *:* a hosszútávú helyesbítések maradékainak négyzetes középérték jelzése.

Kódolás: 0 = a helyesbítési maradékok lineárisan összegzettek
1 = a helyesbítési maradékok négyzetes középértékek

RSS_{iono} *:* az ionoszférikus maradékok négyzetes középérték jelzése.

Kódolás: 0 = a helyesbítési maradékok lineárisan összegzettek
1 = a helyesbítési maradékok négyzetes középértékek

$C_{covariance}$*:* Egy, a kvantálási hatás kiegyenlítésére használatos tényező, akkor, amikor a 28. típusú közlemény felhasználásra kerül.

1. Megjegyzés. – Az a_i *és a* t_{lat} *paraméterek 7. típusú közleményben kerülnek leadásra. Az összes többi paraméter 10. típusú közleményben kerül leadásra.*

2. Megjegyzés. – Ha a 28. típusú közlemény nem kerül leadásra, akkor a $C_{covariance}$ *nem alkalmazható.*

3.5.4.8 *Idő paraméterek.* Az idő paramétereknek, amikor használatosak, a következőknek kell lenniük:

Egyeztetett Világidő /UTC/ szabvány azonosító: az Egyeztetett Világidő /UTC/ referencia forrásának a jelzése a B-35. táblázatban meghatározottaknak megfelelően.

Globális Helymeghatározó Rendszer /GPS/ hét – idő számlálás: Az előző GPS hétről történő átállás óta eltelt idő másodperc száma (hasonló a 3.1.1.2.6.1 pontban megadott GPS paraméterrel, de 1-másodperc felbontású).

Globális Helymeghatározó Rendszer /GPS/ hét szám (hét számlálás): lásd a 3.1.1.2.6.2 pontot.

GLONASS jelzés: egy zászló jelzi azt, ha GLONASS idő paraméterek kerülnek biztosításra.

Kódolás: 0 = A GLONASS idő paraméterek nincsenek biztosítva.
1 = A GLONASS idő paraméterek biztosítva vannak.

B-35. táblázat: Egyeztetett Világidő /UTC/ szabvány azonosító

Egyeztetett Világidő /UTC/ szabvány azonosító	Egyeztetett Világidő /UTC/ szabvány
0	A Kommunikációs Kutatási Laboratórium, Tokyo, Japán, által kezelt Egyeztetett Világidő
1	Az Egyesült Államok Országos Szabványügyi és Technológiai Intézete által kezelt Egyeztetett Világidő
2	Az Egyesült Államok Tengerészeti Obszervatóriuma által kezelt Egyeztetett Világidő
3	A Nemzetközi Súly- és Mértékegység Hivatal által kezelt Egyeztetett Világidő
4	Az Egyeztetett Világidő Európai Laboratórium általi kezelésére fenntartva
5 – 6	Tartalék
7	Egyeztetett Világidő nincs biztosítva.

GLONASS idő eltolás ($\delta a_{GLONASS}$) : Egy, a GLONASS idő és a Műhold Bázisú Kiegészítő Rendszer /SBAS/ hálózati ideje közötti eltolás állandó részét képviselő paraméter.

Megjegyzés. – Ha a Műhold Bázisú Kiegészítő Rendszer /SBAS/ nem támasztja alá a GLONASS-t, akkor a $\delta a_{GLONASS}$ nem alkalmazható.

Egyeztetett Világidő /UTC/ paraméterek: Az A_{1SNT}, A_{0SNT}, t_{0t}, WN_t, Δt_{LS}, WN_{LSP}, DN és Δt_{LSF} azok, amelyek a 3.1.1.3.3.6 pontban leírásra kerültek, avval a kivétellel, hogy a Műhold Bázisú Kiegészítő Rendszer /SBAS/ paraméterek a Műhold Hálózat Időt /SNT/ vonatkoztatják az Egyeztetett Világidőhöz, nem pedig a Globális Helymeghatározó Rendszer /GPS/ idejét.

Megjegyzés. – Az összes paraméter 12. típusú közleményben kerül leadásra.

3.5.4.9 *Szolgáltatási körzet paraméterek.* A szolgáltatási körzet paramétereknek a következőknek kell lenniük:

Adatkibocsátás, szolgáltatás (IODS): annak jelzése, hogy a körzetben egy szolgáltatás változás kerül biztosításra.

A szolgáltatási közlemények száma: A különböző 27 típusú Műhold Bázisú Kiegészítő Rendszer szolgáltatási közlemény száma kerül leadásra. (az érték egy 1-es eltolással kerül kódolásra).

Szolgáltatási közlemény szám: A 27. típusú közlemény csomagon belül a pillanatnyilag adott közleményt azonosító sorszám (1.-től a szolgáltatási közlemények száma egy 1-es eltolással kerül kódolásra).

A körzetek száma: Azon szolgáltatási körzetek száma, amelyekre a közleményben koordináták kerülnek leadásra.

Elsőbbségi kód: A közlemény elsőbbségének jelzése, ha két közlemény átfedő körzeteket határoz meg. A magasabb értékű elsőbbségi kóddal rendelkező közlemény kapja az elsőbbséget. Amikor az elsőbbségi kód egyenlő, akkor az alacsonyabb Felhasználói Differenciál Távolságmérési Hiba Teljesítőképesség csökkenési tényezőjű (δUDRE) közlemény kapja az elsőbbséget.

δUDRE jelzés-belül: a körzeti Felhasználói Differenciál Távolságmérési Hiba Teljesítőképesség csökkenési tényező (δUDRE) jelzése, ami alkalmazható a közleményben – a B-36. táblázatnak megfelelően – meghatározott bármely körzeten belüli helyre.

δUDRE jelzés-kívül: a körzeti Felhasználói Differenciál Távolságmérési Hiba Teljesítőképesség csökkenési tényező (δUDRE) jelzése, ami alkalmazható az összes, a jelenleg adott 27. típusú közleményben – a B-36. táblázatnak megfelelően – meghatározott körzeten kívül levő helyre.

Koordináta, földrajzi szélesség: egy körzet sarkának földrajzi szélessége.

Koordináta, földrajzi hosszúság: egy körzet sarkának földrajzi hosszúsága.

A körzet alakja: annak a jelzése, hogy a körzet háromszög vagy négyszög alakú-e.

Kódolás: 0 = háromszög
1 = négyszög

1. Megjegyzés. – A Koordináta 3-nak Koordináta 1 földrajzi szélességi és Koordináta 2 földrajzi hosszúság koordinátája van. Ha egy terület négyszög alakú, akkor a Koordináta 4-nek Koordináta 2 földrajzi szélességű koordinátája és Koordináta 1 földrajzi hosszúsági koordinátája van. A körzet határát a kapcsolódó koordináták képezik az 1-2-3-1 sorrendben (háromszög), vagy az 1-3-2-4-1 sorrendben (négyszög). A határvonal szakaszoknak vagy azonos földrajzi szélességük, azonos földrajzi hosszúságuk van, vagy állandó lejtésű földrajzi szélességi fokokban/földrajzi hosszúsági fokokban megadott határvonala van. A földrajzi szélesség, vagy hosszúság változás bármilyen határvonal szakasz mentén két koordináta között ±180 foknál kevesebb.

2. Megjegyzés. – Az összes paraméter 27. típusú közleményben kerül továbbításra.

3.5.4.10 *Óra-efemerisz kovariancia mátrix paraméterek.* – Az óra-efemerisz kovariancia mátrix paramétereknek a következőknek kell lenni:

PRN maszk szám: Lásd a 3.5.4.1 pontot.

Lépték kitevő: A Cholesky faktorizációs elemek kódolására használatos lépték tényező kiszámításának együtthatója.

Cholesky Faktorizációs Elemek ($E_{i,j}$): Egy felső háromszög mátrix azon elemei, amelyek az információt az óra és efemerisz kovariancia mátrixban tömörítik. Ezek az elemek használatosak a Felhasználói Differenciál Távolságmérési Hiba (UDRE) becslés, teljesítőképesség csökkenési tényező (δUDRE) kiszámításához a felhasználó helyzetének függvényeként.

3.5.5 AZ ADATFELHASZNÁLÁSI PROTOKOLOK MEGHATÁROZÁSA

Megjegyzés. – Ez a rész azoknak a nem-légijármű fedélzeti, vagy légijármű fedélzeti alkotó-elemek paramétereinek a meghatározását adja meg, amelyek nem kerülnek továbbításra. Ezek a paraméterek, amelyek a Műhold Bázisú Kiegészítő Rendszerek /SBAS/ közötti együttműködő képesség biztosításához szükségesek, használatosak a navigációs megoldás és azok *sértetlenségének meghatározásához (védelmi szintek).*

3.5.5.1 *Geostacionárius pálya /GEO/ helyzet és óra*

3.5.5.1.1 *GEO helyzet számítás.* Egy Geostacionárius pálya számított helyzete bármely t_k időpontban a következő:

$$\begin{bmatrix}\hat{X}_G\\ \hat{Y}_G\\ \hat{Z}_G\end{bmatrix} = \begin{bmatrix}X_G\\ Y_G\\ Z_G\end{bmatrix} + \begin{bmatrix}\dot{X}_G\\ \dot{Y}_G\\ \dot{Z}_G\end{bmatrix}(t - t_{0,GEO}) + \frac{1}{2}\begin{bmatrix}\ddot{X}_G\\ \ddot{Y}_G\\ \ddot{Z}_G\end{bmatrix}(t - t_{0,GEO})^2$$

3.5.5.1.2 *GEO óra helyesbítés.* Az óra helyesbítést egy Műhold Bázisú Kiegészítő Rendszerű /SBAS/ Geostacionárius pályájú /GEO/ műhold *i*-re a következő egyenletnek megfelelően kell alkalmazni:

$$t = t_G - \Delta t_G$$

ahol:

t	= SBAS hálózati idő;
t_G	= a GEO kód fázis ideje a közlemény továbbításának időpontjában; és
Δt_G	= a GEO kód fázis eltolása.

3.5.5.1.2.1 A Geostacionárius pálya /GEO/ kód fázis eltolása (Δt_G) bármely *t* időpontban a következő:

$$\Delta t_G = a_{Gf0} + a_{Gf1}(t - t_{0,GEO})$$

ahol: $(t - t_{0,GEO})$ a nap-vége átmenetre van helyesbítve.

3.5.5.2 *Hosszútávú helyesbítések*

3.5.5.2.1 *Globális Helymeghatározó Rendszer /GPS/ óra helyesbítés.* Az óra helyesbítést egy Globális Helymeghatározó Rendszer /GPS/ műhold *i*-re a következő egyenletnek megfelelően kell alkalmazni:

$$t = t_{SV,i} - [(\Delta t_{SV,i})_{L1} + \delta\Delta t_{SV,i}]$$

ahol:

t	=	A Műhold Bázisú Kiegészítő Rendszer /SBAS/ hálózat ideje;
$t_{SV,i}$	=	A Globális Helymeghatározó Rendszer /GPS/ műhold ideje a közlemény továbbításakor;
$(\Delta t_{SV,i})_{L1}$	=	A műhold Ál-véletlen zaj /PRN/ kódjainak fázis eltolása, ahogy az a 3.1.2.2 pontban meghatározásra került; és
$\delta\Delta t_{SV,i}$	=	A kód fázis eltolási helyesbítése.

3.5.5.2.1.1 Az óra idő hiba számítás ($\delta\Delta t_{SV,i}$) a Globális Helymeghatározó Rendszer /GPS/ vagy Műhold Bázisú Kiegészítő Rendszerű /SBAS/ műhold *i* -re a nap bármely t_k időpontjában a következő:

$$\delta\Delta t_{SV,i} = \delta a_{i,f0} + \delta a_{i,f1}(t_k - t_{i,LT})$$

3.5.5.2.2 *GLONASS óra helyesbítés.* Az *i* GLONASS műhold óra helyesbítését a következő képlet szerint kell alkalmazni:

$$t = t_{SV,i} + \tau_n(t_b) - \gamma_n(t_b)(t_{SV,i} - t_b) - \delta\Delta t_{SV,i}$$

ahol:

t	=	A Műhold Bázisú Kiegészítő Rendszer /SBAS/ hálózat
$t_{SV,i}$	=	A GLONASS műhold ideje a közlemény továbbításakor
t_b, $\tau_n(t_b)$, $\gamma_n(t_b)$	=	GLONASS idő paraméterek, ahogy zok a 3.2.2.2 pontban meghatározásra kerültek
$\delta\Delta t_{SV,i}$	=	A kód fázis eltolás helyesbítése

A kód fázis eltolás helyesbítése a $\delta\Delta t_{SV,i}$ az *i* GLONASS műholdra:

$$\delta\Delta t_{SV,i} = \delta a_{i,f0} + \delta a_{i,f1}(t - t_{i,LT}) + \delta a_{i,GLONASS}$$

ahol a $(t - t_{i,LT})$ a nap-vége átmenetre van helyesbítve. Ha a sebesség kód = 0, akkor a $\delta a_{i,f1} = 0$.

3.5.5.2.3 *Műhold helyzet helyesbítés.* Az SBAS-helyesbített vektor egy műhold helyzetsor rendszerű, vagy SBAS műhold *i*-re a *t* időpontjában a következő:

$$\begin{bmatrix} x_i \\ y_i \\ z_i \end{bmatrix}_{\text{helyesbített}} = \begin{bmatrix} x_i \\ y_i \\ z_i \end{bmatrix} + \begin{bmatrix} \delta x_i \\ \delta y_i \\ \delta z_i \end{bmatrix} + \begin{bmatrix} \delta \dot{x}_i \\ \delta \dot{y}_i \\ \delta \dot{z}_i \end{bmatrix} (t - t_{i,LT})$$

ahol:

$(t - t_{i,LT})$ a nap-vége átmenetre van helyesbítve; és

$[x_i\ y_i\ z_i]^T$ = a műhold helyzetsor rendszerű, vagy SBAS műhold helyzet vektora, ahogy az a 3.1.2.3, 3.2.2.3 és 3.5.5.1.1 pontokban meghatározásra került.

Ha a sebesség kód = 0, akkor $\begin{bmatrix} \delta \dot{x}_i & \delta \dot{y}_i & \delta \dot{z}_i \end{bmatrix}^T = \begin{bmatrix} 0 & 0 & 0 \end{bmatrix}^T$.

3.5.5.3 *Pszeudo-távolság helyesbítések.* A helyes letelt pszeudo-távolság a *t* időpontban az *i* műholdra a következő:

$$PR_{i,\text{helyesbített}} = PR_i + FC_i + RRC_i\,(t - t_{i,0f}) + IC_i + TC_i$$

Ahol:

PR_i	=	A mért pszeudo-távolság a műhold óra helyesbítés alkalmazása után;
FC_i	=	A gyors helyesbítés;
RRC_i	=	A távolság-meghatározási változás helyesbítés;
IC_i	=	Az ionoszférikus helyesbítés;
TC_i	=	A troposzférikus helyesbítés (a negatív érték a troposzféra késleltetést jelenti); és
$t_{i,0f}$	=	A legújabb gyors helyesbítés felhasználhatósági ideje, ami a Műhold Hálózat Idő másodperc ’korszakának’ a kezdete, ami egybeesik az SBAS műholdnál a közlemény blokk első jeleinek továbbításával.

3.5.5.4 *Távolság-meghatározási változás helyesbítése (RRC).* A Távolság-meghatározási változás helyesbítés az *i* műholdra a következő:

$$RRC_i = \frac{FC_{i,current} - FC_{i,previous}}{t_{i,0f} - t_{i,0f\_previous}}$$

Ahol:

$FC_{i,current}$ /jelenlegi/	=	A legújabb gyors helyesbítés;
$FC_{i,previous}$ /előző/	=	Az előző gyors helyesbítés;
$t_{i,0f}$	=	Az $FC_{i,current}$ felhasználhatósági ideje;
$t_{i,0f\_previous}$ /előző/	=	Az $FC_{i,previous}$ felhasználhatósági ideje.

3.5.5.5 *Sugárzott iooszférikus helyesbítések*

3.5.5.5.1 *Az Ionoszférikus behatolási pont (IPP) helye.* Egy Ionoszférikus behatolási pont (IPP) helye úgy került meghatározásra, hogy az a vevőtől a műholdhoz vezető vonalszakasznak és a WGS-84 ellipszoid felett állandó 350 km-es magasságon lévő ellipszoidnak a metszéspontja. A hely WGS-84 földrajzi szélességben (ϕ_{pp}) és földrajzi hosszúságban (λ_{pp}) van meghatározva.

3.5.5.5.2 *Ionoszférikus helyesbítés.* Az ionoszférikus helyesbítés az *i* műholdra a következő:

$$IC_i = -F_{pp}\,\tau_{vpp}$$

Ahol:

F_{pp}	=	Az elhajlási tényező = ; $\left[1-\left(\frac{R_e\cos\theta_i}{R_e+h_1}\right)^2\right]^{-\frac{1}{2}}$
τ_{vpp}	=	Az interpolált függőleges ionoszférikus késés kiszámítás (3.5.5.5.3);
R_e	=	6 378,1363 km;
θ_i	=	Az *i* műhold magassági szöge; és
h_I	=	350 km

Megjegyzés. – A GLONASS műholdakra az (IC_i) ionoszférikus helyesbítést a GLONASS-GPS frekvenciák arányának $(f_{GLONASS}/f_{GPS})^2$ *négyzetével kell szorozni.*

3.5.5.5.3 *Interpolált függőleges ionoszférikus késés kiszámítás*

Amikor négy pont kerül az interpolálásnál felhasználásra, akkor az interpolált függőleges ionoszférikus késés kiszámítás a földrajzi szélességnél ϕ_{pp} és a földrajzi hosszúságnál λ_{pp} a következő:

$$\tau_{vpp} = \sum_{k-1}^{4} W_k \tau_{vk}$$

ahol:

τ_{vk} : a sugárzási hálózati pont függőleges késési értékei az Ionoszférikus Rácspont /IGP/ rács k-dik sarkánál, hogy az a B-13. ábrán bemutatásra kerül.

$W_1 = x_{pp}\, y_{pp}$

$W_2 = (1 - x_{pp})\, y_{pp}$

$W_3 = (1 - x_{pp})\,(1 - y_{pp})$

$W_4 = x_{pp}\,(1 - y_{pp})$

3.5.5.5.3.1 Az N85° és az S85° közötti Ionoszférikus behatolási pontokra:

$$x_{pp} = \frac{\lambda_{pp} - \lambda_1}{\lambda_2 - \lambda_1}$$

$$y_{pp} = \frac{\phi_{pp} - \phi_1}{\phi_2 - \phi_1}$$

ahol:
λ_1 = az Ionoszférikus Rácspontok /IGP/ földrajzi hosszúsága az Ionoszférikus behatolási ponttól /IPP/ nyugatra;
λ_2 = az IGP földrajzi hosszúsága az IPP-től keletre;
ϕ_1 = az Ionoszférikus Rácspontok /IGP/ földrajzi szélessége az Ionoszférikus behatolási ponttól /IPP/ délre;
ϕ_2 = az IGP földrajzi szélessége az IPP-től északra.

Megjegyzés. – Ha a λ_1 és λ_2 a földrajzi hosszúságban 180 fokban keresztező, akkor az x_{pp} számításnál figyelembe kell venni a megszakítást a földrajzi hosszúság értékeknél.

3.5.5.5.3.2 Az N85°-tól északra, vagy az S85°-tól délre lévő Ionoszférikus behatolási pontokra /IPP/:

$$y_{pp} = \frac{|\phi_{pp} - \phi_1|}{10^\circ}$$

$$x_{pp} = \frac{\lambda_{pp} - \lambda_3}{90^\circ} \times (1 - 2\, y_{pp}) + y_{pp}$$

ahol:
λ_1 = az Ionoszférikus behatolási ponttól /IPP/ keletre lévő második Ionoszférikus Rácspont /IGP/ földrajzi hosszúsága;
λ_2 = az IPP-től nyugatra lévő második IGP földrajzi hosszúsága;
λ_3 = az IPP-től nyugatra lévő legközelebbi IGP földrajzi hosszúsága;
λ_4 = az IPP-től keletre lévő legközelebbi IGP földrajzi hosszúsága.

Amikor az interpoláláshoz három pont kerül felhasználásra, akkor az interpolált függőleges ionoszférikus késés kiszámítás a következő:

3.5.5.5.3.3 Az S75°és N75° közötti pontokra:

$$\tau_{vpp} = \sum_{k=1}^{3} W_k \tau_{vk}$$

ahol:
$W_1 = y_{pp}$;
$W_2 = 1 - x_{pp} - y_{pp}$; és
$W_3 = x_{pp}$.

3.5.5.5.3.4 Az x_{pp} és az y_{pp} úgy kerül kiszámításra, ahogy az a négy-pontos interpolációnál van, kivéve azt, hogy a λ_1 és ϕ_1 mindig az IGP2 földrajzi hosszúsága és földrajzi szélessége, és a λ_2 és ϕ_2

a másik földrajzi hosszúság és földrajzi szélesség. Az IGP2 mindig a három pont által meghatározott háromszög átfogójával szemben lévő csúcs, az 1. Ionoszférikus Rácspontnak /IGP1/ ugyanaz a földrajzi hosszúsága, mint az IGP2-nek, és az IGP3-nak ugyanaz a földrajzi szélessége, mint az IGP2-nek (a B-14. ábrán egy példa került bemutatásra).

3.5.5.5.3.5 Az N75°-tól északra és az S75°-tól délre lévő pontokra a három-pontos interpoláció nincs biztosítva.

3.5.5.5.4 *Az Ionoszférikus Rácspontok /IGP-k/ kiválasztása.* Az Ionoszférikus Rácspontok kiválasztásának protokolja a következő:

a) Az N60° és S60° közötti Ionoszférikus behatolási pontokra /IPP/:

1) amikor négy Ionoszférikus Rácspont /IGP/ egy 5-fokszor 5-fokos cellát határoz meg az Ionoszférikus behatolási pont /IPP/ körül, az IGP maszkban "1" van állítva, akkor ezek kiválasztásra kerültek; vagy

2) amikor bármilyen három IGP egy 5-fokszor 5-fokos háromszöget határoz meg, ami körülhatárolja az IPP-t, az IGP maszkban "1" van állítva, akkor ezek kiválasztásra kerültek; vagy

3) amikor bármely négy Ionoszférikus Rácspont /IGP/ egy 10-fokszor 10-fokos cellát határoz meg az Ionoszférikus behatolási pont /IPP/ körül, az IGP maszkban "1" van állítva, akkor ezek kiválasztásra kerültek; vagy
4) amikor bármilyen három IGP egy 10-fokszor 10-fokos háromszöget határoz meg, ami körülhatárolja az IPP-t, az IGP maszkban "1" van állítva, akkor ezek kiválasztásra kerültek; vagy

5) egy ionoszférikus helyesbítés nem áll rendelkezésre.

b) Egy, az N60° és N75°, vagy az S60° és S75° közötti IPP-kre:

1) amikor négy Ionoszférikus Rácspont /IGP/ egy 5-fokos földrajzi szélességű és 10-fokos földrajzi hosszúságú cellát határoz meg az Ionoszférikus behatolási pont /IPP/ körül, az IGP maszkban "1" van állítva, akkor ezek kiválasztásra kerültek; vagy

2) amikor bármilyen három IGP egy 5-fokos földrajzi szélességű és 10-fokos földrajzi hosszúságú háromszöget határoz meg, ami körülhatárolja az IPP-t, az IGP maszkban „1" van állítva, akkor ezek kiválasztásra kerültek; vagy

3) amikor bármely négy Ionoszférikus Rácspont /IGP/ egy 10-fokszor 10-fokos cellát határoz meg az Ionoszférikus behatolási pont /IPP/ körül, az IGP maszkban „1" van állítva, akkor ezek kiválasztásra kerültek; vagy

4) amikor bármilyen három IGP egy 10-fokszor 10-fokos háromszöget határoz meg, ami körülhatárolja az IPP-t, az IGP maszkban „1" van állítva, akkor ezek kiválasztásra kerültek; vagy

5) egy ionoszférikus helyesbítés nem áll rendelkezésre.

c) Egy, az N75° és N85°, vagy az S75° és S85° közötti Ionoszférikus behatolási pontra /IPP/:

1) Amikor a két legközelebbi Ionoszférikus Rácspont /IGP/ a 75°-nál van, és a két legközelebbi IGP a 85°-nál van (30°-os földrajzi hosszúsági elkülönítéssel, ha a 9., vagy a 10. sáv használatos, az egyéb esetekben 90°-kal elkülönítve), és az IGP maszk „1"-re van állítva, akkor egy 10-fokszor 10-fokos cella van lineárisan interpolálva a 85°-os Ionoszférikus Rácspontok között azért, hogy olyan virtuális Ionoszférikus Rácspontokat adjon a földrajzi hosszúságoknál, ami egyenlő a 75°-nál lévő Ionoszférikus Rácspontok földrajzi hosszúságával; vagy

2) egy ionoszférikus helyesbítés nem áll rendelkezésre.

d) Egy, az N85°-tól északra eső Ionoszférikus behatolási pontra /IPP/:

1) amikor a négy Ionoszférikus Rácspont /IGP/ az N85° földrajzi szélességnél és a W180°, W90°, 0° és E90°-nál van, és az IGP maszkban az „1” van beállítva, akkor ezek kiválasztásra kerültek, vagy

2) egy ionoszférikus helyesbítés nem áll rendelkezésre.

e) Egy, az S85°-tól délre eső Ionoszférikus behatolási pontra /IPP/:

1) amikor a négy Ionoszférikus Rácspont /IGP/ az S85° földrajzi szélességnél és a W140°, W50°, E40° és E130°-nál van, és az IGP maszkban az „1” van beállítva, akkor ezek kiválasztásra kerültek, vagy

2) egy ionoszférikus helyesbítés nem áll rendelkezésre.

Megjegyzés. – Ez a kiválasztás csak a maszkban biztosított információn alapszik, tekintet nélkül arra, hogy a kiválasztott Ionoszférikus Rácspont /IGP/ ellenőrzött, „Nem-ellenőrzött” vagy „Ne használja” helyzetű. Ha a kiválasztott IGP-k bármelyike „Ne használja” helyzetűként kerül azonosításra, akkor az ionoszférikus helyesbítés nem áll rendelkezésre. Ha négy Ionoszférikus Rácspont került kiválasztásra, és a négyből egy „Nem-ellenőrzött” helyzetűként kerül azonosításra, akkor a hárompontos interpoláció kerül alkalmazásra, ha az Ionoszférikus Rácspont azon a háromszögű területen belül van, amelyet a biztosított három helyesbítés lefed.

3.5.5.6 *Védelmi szintek.* A vízszintes védelmi szint (HPL) és a függőleges védelmi szint (VPL) a következő:

$$HPL_{SBAS} = \begin{cases} K_{H,NPA} \times d_{major} & \text{Az útvonalra a nem-precíziós megközelítési (NPA) módokig} \\ K_{H,PA} \times d_{major} & \text{A precíziós megközelítési (PA) és a függőleges vezetéses megközelítési módokra (APV), és} \end{cases}$$

$$VPL_{SBAS} = K_{V,PA} \times d_V$$

ahol:

$$d_V^2 = \sum_{i=1}^{N} s_{v,i}^2 \, \sigma_i^2$$

= Az a négyzetes középérték eloszlási model, ami összeköti a valódi hiba eloszlást a függőleges tengelyben;

$$d_{major} = \sqrt{\frac{d_x^2 + d_y^2}{2} + \sqrt{\left(\frac{d_x^2 - d_y^2}{2}\right) + (d_{xy})^2}}$$

ahol:

$d_x^2 = \sum_{i=1}^{N} s_{x,i}^2 \sigma$ = Az a négyzetes középérték eloszlási model, ami összeköti a valódi hiba eloszlást az x - tengelyben;

$d_y^2 = \sum_{i=1}^{N} s_{y,i}^2 \sigma$ = Az a négyzetes középérték eloszlási model, ami összeköti a valódi hiba eloszlást az y - tengelyben;

$d_{xy} = \sum_{i=1}^{N} s_{x,i} s_{y,}$ = Kovariancia eloszlási model az x- és y-tengelyben;

Ahol:

$s_{x,i}$ = Az x-irány helyzet hibáinak parciális deriváltja az i-ik műhold pszeudo- távolság hibájára vonatkozóan;

$s_{y,i}$ = Az y-irány helyzet hibáinak parciális deriváltja az i-ik műhold pszeudo- távolság hibájára vonatkozóan;

$s_{V,i}$ = A fügőleges irány helyzet hibáinak parciális deriváltja az i-ik műhold pszeudo-távolság hibájára vonatkozóan; és

$\sigma^2_i = \sigma^2_{i,flt} + \sigma^2_{i,UIRE} + \sigma^2_{i,air} + \sigma^2_{i,tropo}$.

A ($\sigma^2_{i,flt}$ és $\sigma^2_{i,UIRE}$) négyzetes középértékek a 3.5.5.6.2 és 3.5.5.6.3.1 pontokban kerültek meghatározásra. A ($\sigma^2_{i,air}$ és $\sigma^2_{i,tropo}$) paramétereket a légijármű fedélzeti elemek határozzák meg (3.5.8.4.2 és 3.5.8.4.3).

Az x- és y-tengelyek a helyi vízszintes síkban lévőként kerültek meghatározásra, és a v-tengely jelenti a helyi függőlegest.

Egy általános legkisebb-négyzetek helyzet megoldásként, az S mátrix vetülete a következő:

$$S \equiv \begin{bmatrix} S_{x,1} & S_{x,2} & \cdots & S_{x,N} \\ S_{y,1} & S_{y,2} & \cdots & S_{y,N} \\ S_{v,1} & S_{v,2} & \cdots & S_{v,N} \\ S_{t,1} & S_{t,2} & \cdots & S_{t,N} \end{bmatrix} = (G^T \times W \times G)^{-1} \times G^T \times W$$

ahol:

G_i = [$-\cos El_i \cos Az_i$ $-\cos El_i \sin Az_i$ $-\sin El_i$ 1] = a G i-dik sora;

$$W^{-1} = \begin{bmatrix} w_1 & 0 & \dots & 0 \\ 0 & w_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & & \dots & w_i \end{bmatrix};$$

El_i = az i-dik távolságmérési forrás magassági szöge (fokokban);

Az_i = az i-dik távolságmérési forrás oldalszöge az x-tengelytől az óramutató járásával ellentétes irányban mérve, fokokban; és
w_i = az *i* műholdhoz kapcsolódó inverz súlyozás.

1. Megjegyzés. – Az olvashatóság növelése érdekében az i *indexek a védő mátrixok egyenleteiből elhagyásra kerültek.*

2. Megjegyzés. – A súlyozatlan legkisebb négyzetek megoldásáért, a súlyozási mátrix egy azonosító mátrix (w_i = 1).

3.5.5.6.1 *A 'K' értékek meghatározása.* A 'K' értékek az alábbiak:

$$K_{H,NPA} = 6{,}18;$$
$$K_{H,PA} = 6{,}0; \text{ és}$$
$$K_{V,PA} = 5{,}33.$$

3.5.5.6.2 *A gyors és hosszútávú helyesbítési hiba model meghatározása.* Amikor gyors és hosszútávú helyesbítések /Geostacionárius pálya /GEO/ távolságmérési paraméterek alkalmazásra kerülnek, és a teljesítőképesség csökkenési paraméterek is alkalmazottak, akkor:

$$\sigma^2_{i,flt} = \begin{cases} [(\sigma_{i,UDRE})(\delta_{UDRE}) + \varepsilon_{fc} + \varepsilon_{rrc} + \varepsilon_{ltc} + \varepsilon_{er}]^2, & \text{ha } RSS_{UDRE} = 0 \text{ (10. típusú közlemény)} \\ [(\sigma_{i,UDRE})(\delta_{UDRE})]^2 + \varepsilon^2_{fc} + \varepsilon^2_{rrc} + \varepsilon^2_{ltc} + \varepsilon^2_{er}, & \text{ha } RSS_{UDRE} = 1 \text{ (10. típusú közlemény)} \end{cases}$$

Ahol:
Ha a 27. típusú közleményt használják, akkor a δ_{UDRE} egy körzeti – fajlagos tényező, ahogy az a 3.5.4.9 részben meghatározásra került.
Ha a 28. típusú közleményt használják, akkor a δ_{UDRE} egy műhold – fajlagos tényező, ahogy az a 3.5.5.6.2.5 részben meghatározásra került.
Ha egyik közleményt sem használják, akkor a $\delta_{UDRE} = 1$.

Amikor a gyors és hosszútávú helyesbítések/Geostacionárius pálya /GEO/ távolságmérési paraméterek nem kerülnek alkalmazásra, és a teljesítőképesség csökkenési paraméterek sem alkalmazottak, akkor:

$$\sigma^2_{i,flt} = [\,(\sigma_{i,UDRE})\,(\delta_{UDRE}) + 8 \text{ m}\,]^2 .$$

Amikor a gyors helyesbítések, vagy a hosszútávú helyesbítések/Geostacionárius pálya /GEO/ távolságmérési paraméterek nem kerülnek egy műholdra alkalmazásra, vagy ha egy 28. típusú efemerisz kovariancia közlemény nem kerül vételre a műholdra vonatkozóan, de vételre kerül egy aktív 28. típusú közlemény egy eltérő műholdra vonatkozóan, akkor :

$$\sigma^2_{i,flt} = (60)^2 \text{ m}^2 .$$

3.5.5.6.2.1 *Gyors helyesbítés teljesítőképesség csökkenés.* A teljesítmény-csökkenési paraméter a gyors helyesbítési adatokra a következő:

$$\varepsilon_{fc} = \frac{a\,(t - t_u + t_{lat})^2}{2}$$

ahol:
t = A pillanatnyi idő;
t_u = (Felhasználói Differenciál Távolságmérési Hiba Jelzés /$UDREI_i$/ referencia idő): Ha az Adatkibocsátás Gyors Helyesbítés /$IODF_j$/ ≠ 3, a Műhold Hálózat Idő /SNT/ 1-másodperces korszakának kezdési ideje egybeesik annak a közlemény blokknak a továbbítása kezdetével, ami

magába foglalja a legutolsó $UDREI_i$ adatait (2.-tól 6.-ig típusú, vagy 24. típusú közlemények), ami az $IODF_j$ -t a használatos gyors helyesbítéshez illeszti. Ha az $IODF_j$ = 3-al, az SNT 1-másodperces korszakának kezdési ideje egybeesik annak a közleménynek a továbbításával, amely az i-dik műholdra a gyors helyesbítést magába foglalja; és

t_{lat} = (Ahogy az a 3.5.4.7 pontban meghatározásra került.)

Megjegyzés. – A 2.-tól az 5.-ig típusú és a 24. típusú közleményekben továbbított Felhasználói Differenciál Távolságmérési Hibáknál /UDREs/ a t_u egyenlő a gyors helyesbítés alkalmazhatósági idejével, mivel azok ugyanabban a közleményben vannak. A 6. típusú közleményben továbbított UDRE-k és ha az Adatkibocsátás Gyors Helyesbítés /IODF/ = 3, akkor a t_u ugyancsak egyenlő a gyors helyesbítések (t_{0f}) alkalmazhatósági idejével. A 6. típusú közleményben továbbított UDRE-k és ha az IODF ≠ 3, akkor a t_u úgy van meghatározva, hogy az a 6. típusú közlemény első bitjének továbbítási ideje a Geostacionárius pályánál /GEO/.

3.5.5.6.2.2 *Távolság meghatározási változás /RRC/ helyesbítés teljesítőképesség csökkenés*

3.5.5.6.2.2.1 Ha az RRC = 0, akkor $\varepsilon_{rrc} = 0$.

3.5.5.6.2.2.2 Ha az RRC ≠ 0 és az Adatkibocsátás Gyors Helyesbítés /IODF/ ≠ 3, akkor a teljesítőképesség csökkenés a gyors helyesbítési adatokra a következő:

$$\varepsilon_{rrc} = \begin{cases} 0, & \text{ha } (IODF_{current} - IODF_{previous}) \text{MOD } 3 = 1 \\ \left(\frac{aI_{fc}}{4} + \frac{B_{rrc}}{\Delta t}\right)(t - t_{0f}) & \text{ha } (IODF_{current} - IODF_{previous}) \text{MOD } 3 \neq 1 \end{cases}$$

/current = jelenlegi; previous = előző/

3.5.5.6.2.2.3 Ha az RRC ≠ 0 és az IODF = 3, akkor a teljesítőképesség csökkenés a távolság adatokra a következő:

$$\varepsilon_{rrc} = \begin{cases} 0, & \text{ha } \left|\Delta t - \frac{I_{fc}}{2}\right| = 0 \\ \left(\frac{a\left|\Delta t - \frac{I_{fc}}{2}\right|}{2} + \frac{B_{rrc}}{\Delta t}\right)(t - t_{0f}) & \text{ha } \left|\Delta t - \frac{I_{fc}}{2}\right| \neq 0 \end{cases}$$

ahol**:**

t	=	A jelenlegi idő;
$IODF_{current}$	=	A legújabb gyors helyesbítéshez kapcsolódó Adatkibocsátás – Gyors

		helyesbítés /IODF/
$IODF_{previous}$	=	Az előző gyors helyesbítéshez kapcsolódó IODF
Δt	=	$t_{i,0f} - t_{i,0f\_previous}$; és
I_{fc}	=	A felhasználó időzítési intervalluma a gyors helyesbítésekre.

3.5.5.6.2.3 *Hosszútávú helyesbítés teljesítőképesség csökkenés*

3.5.5.6.2.3.1 *Műhold helyzetsor rendszere(k)*

3.5.5.6.2.3.1.1 A sebesség kód = 1-re, a teljesítőképesség csökkenés a hosszútávú helyesbítésekre az *i* műholdra a következő:

$$\varepsilon_{ltc} = C_{ltc\_lsb} + C_{ltc\_v1} \max(0, t_{i,LT} - t, t - t_{i,LT} - I_{ltc\_v1})$$

3.5.5.6.2.3.1.2 A sebesség kód = 0-ra, a teljesítőképesség csökkenés a hosszútávú helyesbítésekre:

$$\varepsilon_{ltc} = C_{ltc\_v0} \left\lfloor \frac{t - t_{ltc}}{I_{lt-v0}} \right\rfloor$$

ahol:
t = a jelenlegi idő;
t_{ltc} = a Geostacionárius Pálya /GEO/ hosszútávú helyesbítési közleménye első bitjének továbbítási ideje; és
[x] = az *x* -nél kisebb legnagyobb egészszám.

3.5.5.6.2.3.2 *Geostacionárius pályájú műholdak.* A teljesítőképesség csökkenési paraméter a hosszútávú helyesbítésekre a következő:

$$\varepsilon_{ltc} = C_{geo\_lsb} + C_{geo\_v} \max(0, t_{0,GEO} - t, t - t_{0,GEO} - I_{GEO})$$

ahol: t = a jelenlegi idő.

3.5.5.6.2.4 *Teljesítőképesség csökkenés az útvonalról a nem-precíziós megközelítésekig*

$$\varepsilon_{er} = \begin{cases} 0, & \text{Amikor sem gyors, sem hosszútávú helyesbítések nincsenek időzítve a precíziós megközelítésre} \\ C_{er}, & \text{Amikor gyors és hosszútávú helyesbítések vannak időzítve a precíziós megközelítésekre} \end{cases}$$

3.5.5.6.2.5 *Felhasználói Differenciál Távolságmérési Hiba /UDRE/ teljesítőképesség csökkenési tényező a 28. típusú közlemény adatokkal számolva.* A δUDRE a következő:

$$\delta_{UDRE} = \sqrt{I^T \cdot C \cdot I} + \varepsilon_c$$

ahol:

$$I = \begin{bmatrix} i_x \\ i_y \\ i_z \\ 1 \end{bmatrix},$$

$$\begin{bmatrix} i_x \\ i_y \\ i_z \end{bmatrix} =$$ egység-vektor a felhasználótól a műholdig a WGS-84 ECEF koordináta rendszerben.

$C = R^T \cdot R$

$\varepsilon_C = C_{kovariancia} \cdot SF$

$SF = 2^{\text{rendű exponenciális} - 5}$

$R = E \cdot SF$

$$E = \begin{bmatrix} E_{1,1} & E_{1,2} & E_{1,3} & E_{1,4} \\ 0 & E_{2,2} & E_{2,3} & E_{2,4} \\ 0 & 0 & E_{3,3} & E_{3,4} \\ 0 & 0 & 0 & E_{4,4} \end{bmatrix}$$

3.5.5.6.3 *Az ionoszférikus helyesbítési hiba modell meghatározása*

3.5.5.6.3.1 *Adási ionoszférikus helyesbítések.* Amikor Műhold Bázisú Kiegészítő Rendszerű /SBAS/-bázisú ionoszférikus helyesbítések kerülnek alkalmazásra, akkor a σ^2_{UIRE} a következő:

$\sigma^2_{UIRE} = F^2_{pp} \times \sigma^2_{UIVE}$

ahol:

F_{pp} = (ahogy a 3.5.5.5.2 pontban meghatározásra került);

$\sigma^2_{UIVE} = \sigma^2_{UIVE} = \sum_{n=1}^{4} W_n \cdot \sigma^2_{n,ionogrid}$ vagy $\sigma^2_{UIVE} = \sigma^2_{UIVE} = \sum_{n=1}^{3} W_n \cdot \sigma^2_{n,ionogrid}$

ugyanazt az ionoszférikus behatolási pont súlyozást (W_n) és a kiválasztott hálózati pontokat felhasználva az ionoszférikus helyesbítésre (3.5.5.5). Az egyes hálózati pontokra ez:

$$\sigma^2_{i,\,ionogrid} = \begin{cases} (\sigma_{GIVE} + \varepsilon_{iono})^2, & \text{ha } RSS_{iono} = 0 \text{ (10. típusú közlemény)} \\ \sigma^2_{GIVE} + \varepsilon^2_{iono}, & \text{ha } RSS_{iono} = 1 \text{ (10. típusú közlemény)} \end{cases}$$

ahol:

$$\varepsilon_{iono} = C_{iono\_step} \left\lfloor \frac{t - t_{iono}}{I_{iono}} \right\rfloor + C_{iono\_ramp}(t - t_{iono});$$

t = a jelenlegi idő;

t_{ltc} = a Geostacionárius Pálya /GEO/ ionoszférikus helyesbítési közleménye első bitjének továbbítási ideje; és

[x] = az *x* -nél kisebb legnagyobb egészszám.

Megjegyzés. – A GLONASS műholdakra, mind a σ_{GIVE}, mind a σ_{IONO} paramétereket meg kell szorozni a GLONASS – GPS frekvenciák $(f_{GLONASS}/f_{GPS})^2$ arányának négyzetével.

3.5.5.6.3.2 *Ionoszférikus helyesbítések.* Amikor Műhold Bázisú Kiegészítő Rendszerű /SBAS/-alapú ionoszférikus helyesbítéseket nem alkalmazzák, akkor a σ^2_{UIRE} a következő:

$$\sigma^2_{UIRE} = MAX\left\{\left(\frac{T_{iono}}{5}\right)^2, (F_{pp} \cdot \tau_{vert})^2\right\}$$

ahol:
T_{iono} = a kiválasztott model szerint számított ionoszférikus késés (GPS helyesbítés, vagy más modell);

F_{pp} = (ahogy a 3.5.5.5.2 pontban meghatározásra került);

$$\tau_{vert} = \begin{cases} 9\text{ m}, & 0 \le |\phi_{pp}| \le 20 \\ 4.5\text{ m}, & 20 < |\phi_{pp}| \le 55; \\ 6\text{ m}, & 55 < |\phi_{pp}| \end{cases}$$; és

ϕ_{pp} = az ionoszférikus behatolási pont földrajzi szélessége.

3.5.5.6.3.3 *GLONASS óra.* A GLONASS óra helyesbítés teljesítőképesség csökkenés paraméter a következő:

$$\varepsilon_{GLONASS\_CLOCK} = C_{GLONASS\_CLOCK} \bullet [t - t_{GLONASS\_CLOCK}]$$

ahol
t = a jelenlegi idő;
$t_{GLONASS\_CLOCK}$ = a Geostacionárius pályánál /GEO/ az időmérési közlemény (MT12) első bitjének továbbítási ideje;
[sc] = az sc-nél kisebb legnagyobb egészszám.

1. Megjegyzés. – A nem-GLONASS műholdakra az $\varepsilon_{GLONASS\_CLOCK}$ = 0.

2. Megjegyzés. – A $C_{GLONASS\_CLOCK}$ = 0,00833 cm/s.

3.5.6 KÖZLEMÉNY TÁBLÁZATOK

Az egyes Műhold Bázisú Kiegészítő Rendszer /SBAS/ közleményeket a B-37. táblázattól a B-53. táblázatig terjedően meghatározott megfelelő közlemény formátummal megegyezően kell kódolni. Az ezekben a táblázatokban lévő összes előjeles paramétert kettős kiegészítővel kell feltűntetni úgy, hogy az előjel bit foglalja el a Legnagyobb Helyértékű Bitet /MSB/.

Megjegyzés. – Az előjeles paraméterek értéktartománya kisebb, mint a jelzett, mivel a maximális pozitív érték egy értékkel kevesebbre van leszűkítve (a jelzett érték mínusz a felbontás).

B-37. táblázat: 0. típus „Ne használja” közlemény

Adat tartalom	Felhasznált bitek	Érték tartomány	Felbontás
Tartalék	212	—	—

B-38. táblázat: 1. típus Ál-véletlen zaj /PRN/ maszk közlemény

Adat tartalom	Felhasznált bitek	Érték tartomány	Felbontás
A 210 PRN kód szám mindegyikére			
Maszk érték	1	0, vagy 1	1
Adatkibocsátás Ál-véletlen zaj /IODP/	2	0, vagy 3	1

Megjegyzés. – Az összes paraméter a 3.5.4.1 pontban került meghatározásra.

B-39. táblázat: 2.-tól 5.-ig terjedő típusok Gyors helyesbítés közlemény

Adat tartalom	Felhasznált bitek	Érték tartomány	Felbontás
Adatkibocsátás – Gyors helyesbítés /$IODF_j$ /	2	0-tól 3-ig	1
Adatkibocsátás – Ál-véletlen zaj /IODP/	2	0-tól 3-ig	1

$E_{2,4}$	10	± 512	1
$E_{3,4}$	10	± 512	1

MEGJEGYZÉSEK: -
1. Az Ál-véletlen zaj /PRN/ maszk szám és az Adatkibocsátás – Ál-véletlen zaj /IODP/ paraméterei a 3.5.4.1 pontban kerültek meghatározásra.

2. Az összes további paraméter a 3.5.4.10 pont szerint meghatározott.

3.5.7 NEM-LÉGIJÁRMŰ FEDÉLZETI ALKOTÓELEMEK

1. Megjegyzés. – Az egy meghatározott Műhold Bázisú Kiegészítő Rendszer /SBAS/ által kínált szolgáltatási szinttől függően, különböző funkciókat lehet teljesíteni, ahogy az a 3. fejezet 3.7.3.4.2 pontjában leírásra került.

2. Megjegyzés. – Azok a paraméterek, amelyekre ebben a részben utalás történik, a 3.5.4 pontban kerültek meghatározásra.

3.5.7.1 *Általános*

3.5.7.1.1 *Szükséges adatok és sugárzási szünetek.* A Műhold Bázisú Kiegészítő Rendszernek /SBAS/ az általa alátámasztott funkciókhoz szükséges adatokat a B-54. táblázatban bemutatottaknak megfelelően kell sugároznia. Ha az SBAS olyan adatokat is sugároz, amelyek egy meghatározott funkcióhoz nem szükségesek, akkor az egyéb funkciókat alátámasztó adatokra vonatkozó követelményeket kell alkalmazni. A biztosított egyes adat-típusoknak az összes adatban való sugárzása közötti maximális időköznek a B-54. táblázatban meghatározottnak kell lenni.

3.5.7.1.2 *A Műhold Bázisú Kiegészítő Rendszer /SBAS/ rádiófrekvenciás ellenőrzése*. Az SBAS-nek ellenőriznie kell a B-55. táblázatban bemutatott SBAS műhold paramétereket és meg kell tennie a jelzett tevékenységeket.

Megjegyzés. – Az SBAS nulla /üres/ közleményeket (63. típusú közlemények) sugározhat minden egyes olyan időrésben, amelyben nincs egyéb sugározandó adat.

3.5.7.1.3 *„Ne használja”*. A Műhold Bázisú Kiegészítő Rendszernek /SBAS/ a „Ne használja” közleményt (0.típusú közlemény) kell sugároznia akkor, amikor a felhasználókat tájékoztatni kell arról, hogy ne használják az SBAS műhold távolságmérési funkcióját és sugárzott adatait.

3.5.7.1.4 *Naptár adatok*. A Műhold Bázisú Kiegészítő Rendszernek /SBAS/ naptár adatokat kell sugározni az SBAS műholdakra (a 3.5.4.3 pontban meghatározottan) hiba nélkül 150 km-re (81 Tengeri mérföld) a tényleges műhold helyzettől. A 17. típusú közleményekben a felhasználatlan naptár időréseket a „0” Ál-véletlen zaj /PRN/ kód számmal kell kódolni. A működési állapotnak és a helyzetnek a műhold állapotát és a szolgáltatás biztosítót kell jeleznie úgy, ahogy az a 3.5.4.3 pontban meghatározásra került.

3.5.7.1.5 **Ajánlás**. – *Az SBAS-nek naptár adatokat kell sugározni az összes SBAS műholdra, a szolgáltatás biztosítótól függetlenül.*

3.5.7.2 *Távolságmérési funkció*. Ha a Műhold Bázisú Kiegészítő Rendszer /SBAS/ távolságmérési funkciót biztosít, akkor annak a 3.5.7.1 pontban leírt követelményekhez kiegészítetten meg kell felelnie az ebben a részben foglalt követelményeknek is.

3.5.7.2.1 *Teljesítmény követelmények*

Megjegyzés. – Lásd a 3. fejezet 3.7.3.4.2.1 pontját.

3.5.7.2.2 *Távolságmérési funkció adatok*. A Műhold Bázisú Kiegészítő Rendszernek /SBAS/ távolságmérési adatokat kell sugározni úgy, hogy az SBAS műhold helymeghatározási hiba a műhold nyomvonalában lévő valamennyi felhasználó részére a rálátási vonalra vetítve 256 méternél kevesebb legyen. Az egyes SBAS műholdaknak egy olyan felhasználói távolság pontosságot /URA/ kell sugározni, amely a Műhold Hálózati Időre /SNT/ vonatkoztatott távolságmérési pontosság szabvány eltérésének a becslését képviseli.

3.5.7.3 *Globális Navigációs Műhold Rendszer /GNSS/ műhold állapot funkció*. Amikor egy Műhold Bázisú Kiegészítő Rendszer /SBAS/ műhold állapot funkciót biztosít, akkor annak meg kell felelni az ebben a részben foglalt követelményeknek is.

3.5.7.3.1 *A műhold állapot funkciók teljesítőképessége*. Az aktív adatok bármilyen érvényes kombinációját véve a Vízszintes Védelmi Szintet /HPL_{SBAS} / a Műhold Bázisú Kiegészítő Rendszeren meghaladó vízszintes hiba valószínűségének (ahogy az a 3.5.5.6 pontban meghatározásra került) 8 egymás után következő másodpercnél hosszabb időben 10^{-7} -nél kisebbnek kell lenni bármely órában, egy nulla várakozási idejű felhasználót feltételezve.

Megjegyzés. – Az aktív adat egy olyan adatként került meghatározásra, amely nem idő-túllépéses a 3.5.8.1.1 pont szerint. Ez a követelmény műholdak helyzetsor rendszere(it) és Műhold Bázisú Kiegészítő Rendszer hibákat foglal magába.

3.5.7.3.2 *Ál-véletlen zaj /PRN/ maszk és Adatkibocsátás – PRN (IODP)*. A Műhold Bázisú Kiegészítő Rendszernek /SBAS/ egy Ál-véletlen zaj /PRN/ maszkot és az Adatkibocsátás – PRN /IODP/ (1. típusú közlemény) kell kisugározni. A PRN maszk értékeknek jelezni kell azt, hogy ez az adat egy Globális Navigáció Műhold Rendszerű /GNSS/ műholdra biztosításra került-e, vagy sem. Az IODP-t meg kell változtatni, amikor változás van a PRN maszkban. Az IODP megváltoztatásának az 1. típusú közleményben az előtt kell megtörténni, mielőtt az IODP bármely más közleményben megváltozik. A 2.-tól az 5.-ig terjedő, a 7., a 24. és a 25. típusú közleményekben lévő IODP-nek egyenlőnek kell lenni az abban a PRN maszk közleményben sugárzott IODP-vel (1. típusú közlemény), amely azoknak a műholdaknak a kijelölésére használatos, amelyre adat került biztosításra abban a közleményben.

B-54. táblázat: Adat sugárzási időközök és biztosított funkciók

Adat típus	Max. sugárzási időtartam	Távolság mérés	GNSS Műhold állapot	Alap differenciál helyesbítés	Pontos Differenciál helyesbítés	Kapcsolódó közlemény típus
Óra-efemerisz kovariancia mátrix	120 s					28

Szolgáltatási szint	300 s					27

MEGJEGYZÉSEK. –
1. Az „R” jelöli azt, hogy az adatot a funkció alátámasztásához sugározni kell.
2. Az „R” azt a speciális kódolást jelöli, ami a 3.5.7.3.3 pontban leírásra került.*
3. A 12.típusú közlemények csak akkor szükségesek, ha az adatok a GLONASS műholdakhoz biztosítottak.

B-55. táblázat: Műhold Bázisú Kiegészítő Rendszer /SBAS/ rádiófrekvenciás ellenőrzés

Paraméter	Referencia	Riasztási határérték	Megkívánt tevékenység
Jel teljesítmény-szint	3. fejezet 3.7.3.4.4.3	Minimum ≅ -161 dBW Maximum ≅ -153 dBW (2. Megjegyzés)	Minimum: a távolságmérési funkció megszűntetése (1. Megjegyzés). Maximum: a sugárzás megszűntetése.

Maximális kód fázis eltérés	3.5.2.6	Nem alkalmazható. (2. és 3. Megjegyzés)	A távolságmérési funkció megszűntetése, kivéve, ha a σ^2_{UDRE} és a Felhasználói Távolságmérési Pontosság /URA/ hibát tükröz.
Konvolúciós kódolás	3.5.2.9	Az összes sugárzott közlemény hibás.	A sugárzás megszűntetése.

MEGJEGYZÉSEK. -
1. A távolságmérési funkció megszűntetését a Felhasználói Távolságmérési Pontosság /URA/ és a σ^2_{UDRE} -nak az arra az SBAS műholdra vonatkozó „Ne használja” sugárzásával lehet végrehajtani.
2. Ezeket a paramétereket a vett jelminőségre (C/N_0 hatás) gyakorolt hatásukon lehet ellenőrizni, mivel ez a felhasználót érintő hatásuk.
3. Riasztási határértékek nincsenek meghatározva, mivel az elõidézett hiba elfogadható, feltéve, ha az a σ^2_{UDRE} és URA paraméterekben fel van tűntetve. Ha a hibát nem lehet feltűntetni, akkor a távolságmérési funkciót meg kell szűntetni.

3.5.7.3.2.1 **Ajánlás**. – *Amikor a PRN maszk megváltoztatásra kerül, akkor az SBAS-nek több alkalommal meg kell ismételnie az 1. típusú közleményt, mielőtt azt bármely más közleményekre vonatkoztatná, azért, hogy biztosítva legyen az, hogy a felhasználó az új maszkot vegye.*

3.5.7.3.3 *Sértetlenségi /integritás/ adatok*. Amikor az SBAS nem biztosítja az alap differenciál helyesbítési funkciót, akkor a gyors helyesbítések, hosszútávú helyesbítések és gyors helyesbítés teljesítőképesség csökkenési paramétereket nullára kódolva kell leadnia az összes, az Ál-véletlen zaj /PRN/ maszkban jelzett látható műholdra.

3.5.7.3.3.1 Amikor az SBAS nem biztosítja az alap differenciál helyesbítési funkciót, akkor az SBAS-nek jeleznie kell azt, hogy a műhold nem kielégítő műszaki állapotú /'egészségtelen'/ („Ne használja"), ha a pszeudo-távolság hiba a 150 métert meghaladja.

3.5.7.3.3.2 Amikor az SBAS nem biztosítja az alap differenciál helyesbítési funkciót, akkor az SBAS-nek jeleznie kell, hogy a műhold „Nem-ellenőrzött", ha a pszeudo-távolság hibát nem lehet meghatározni.

3.5.7.3.3.3 Amikor az SBAS nem biztosítja az alap differenciál helyesbítési funkciót, akkor az SBAS-nek egy Felhasználói Differenciál Távolságmérési Hiba Jelzést /$UDREI_i$ /, a 13.-at kell leadni, ha a műhold nem „Ne használja", vagy „Nem-ellenőrzött" helyzetű.

3.5.7.3.3.4 Az Adatkibocsátás – Gyors Helyesbítés /$IODF_j$ / paraméternek a 2.-tól az 5.-ig terjedő, a 6., vagy a 24. típusú közleményekben 3-al kell egyenlőnek lenni.

3.5.7.4 *Alap differenciál helyesbítési funkció*. Amikor egy Műhold Bázisú Kiegészítő Rendszer /SBAS/ biztosít egy alap differenciál helyesbítési funkciót, akkor annak teljesítenie kell az ebben a részben leírt követelményeket is, kiegészítőleg a 3.5.7.3 pontban meghatározott, a Globális Navigációs Műhold Rendszer /GNSS/ műhold állapot funkciókhoz.

3.5.7.4.1 *Az alap differenciál helyesbítési funkció teljesítőképessége*. Az aktív adatok bármilyen érvényes kombinációját véve a Vízszintes Védelmi Szintet /HPL_{SBAS} / meghaladó vízszintes hiba valószínűségének (ahogy az a 3.5.5.6 pontban meghatározásra került) 8 egymás után következő másodpercnél hosszabb időben 10^{-7}-nél kisebbnek kell lenni bármely órában, egy nulla várakozási idejű felhasználót feltételezve.

Megjegyzés. – Az aktív adat egy olyan adatként került meghatározásra, amely nem idő-túllépéses a 3.5.8.1.1 pont szerint. Ez a követelmény műholdak helyzetsor rendszere(it) és Műhold Bázisú Kiegészítő Rendszer hibákat foglalja magába.

3.5.7.4.2 *Hosszútávú helyesbítések*. Az ugyanazon szolgáltatás biztosítók SBAS műholdjai kivételével, az SBAS-nek meg kell határoznia és sugározni kell a hosszútávú helyesbítéseket minden egyes az Ál-véletlen zaj /PRN/ maszkban (PRN maszk érték „1"-el egyenlő) jelzett, látható Globális Navigációs Műhold Rendszerű /GNSS/ műholdra (lásd a Megjegyzés-t). A hosszútávú helyesbítéseknek olyanoknak kell lenni, hogy a műholdak helyzetsor rendszereinek műhold helyzet hibája a műhold nyomvonalában lévő bármely felhasználó részére a rálátási vonalban ezeknek a hosszútávú helyesbítéseknek az alkalmazása után 256 méternél kevesebb legyen. Az egyes GLONASS műholdakra a Műhold Bázisú Kiegészítő Rendszernek /SBAS/ át kell számítani a műhold koordinátákat WGS-84-re úgy, ahogy az a 3.5.5.2 pontban meghatározásra került a hosszútávú helyesbítéseket megelőzően. Az egyes Globális Helymeghatározó Rendszer /GPS/ műholdakra a sugárzott Adatkibocsátásnak illeszkedniük kell a GPS Adatkibocsátás – Efemerisszel /IODE/ és az Adatkibocsátás – Óra /IODC/ 8. Legkisebb Helyértékű Bitjével, amelyek az óra és efemerisz adatokhoz kapcsolódnak, és a helyesbítések kiszámításához használatosak (3.1.1.3.1.4 és 3.1.1.3.2.2). Az egy GPS műhold általi új efemerisz sugárzásánál az SBAS-nek folytatnia kell az 'öreg' efemerisz felhasználását, azért, hogy a gyors és hosszútávú helyesbítéseket meghatározza legalább 2 percig, de 4 percnél nem tovább. Az egyes GLONASS műholdakra az SBAS-nek kell kiszámítani és továbbítani egy olyan IOD-t, amely egy várakozási és egy érvényességi időközt foglal magába, ahogy az a 3.5.4.4.1 pontban meghatározásra került.

Megjegyzés. – A műhold láthatóságának követelménye magába foglalja a referencia állomások elhelyezését és az azokon a helyeken elért maszk szöget.

3.5.7.4.2.1 **Ajánlás.** – *A pontos távolság meghatározási helyesbítések biztosításához az SBAS-nek a minimálisra kell csökkenteni a műhold efemerisz megszakításait a hosszútávú helyesbítések alkalmazása után.*

3.5.7.4.3 *Gyors helyesbítések*. A Műhold Bázisú Kiegészítő Rendszernek meg kell határozni a gyors helyesbítéseket azokra az egyes látható Globális Navigációs Műhold Rendszer műholdakra, amelyek az Ál-véletlen zaj /PRN/ maszkban meghatározásra kerültek (PRN maszk érték „1"-el egyenlő). Kivéve, ha az IODF = 3, minden alkalommal, amikor a gyors helyesbítés adatok a 'j' típusú (j = 2, 3, 4 vagy 5) közleményben változnak, az Adatkibocsátás – Gyors helyesbítés /$IODF_j$ / sorrendjének „0, 1, 2, 0, …"-nak kell lenni.

Megjegyzés. – Ha egy riasztási helyzet áll fenn, az $IODF_j$ 3-al lehet egyenlő (lásd a 3.5.7.4.5 pontot).

3.5.7.4.4 *Időmérési adatok*. Ha a GLONASS részére adatok kerülnek biztosításra, akkor a Műhold Bázisú Kiegészítő Rendszernek /SBAS/ továbbítania kell az időmérési közleményt (12. típusú közlemény) a GLONASS idő eltolást is beleértve, ahogy az a B-44. táblázatban meghatározásra került.

3.5.7.4.5 *Sértetlenségi /integritás/ adatok.* Minden egyes műholdra, amelyre helyesbítések kerültek biztosításra, a Műhold Bázisú Kiegészítő Rendszernek /SBAS/ sértetlenségi adatokat kell sugározni (Felhasználói Differenciál Távolságmérési Hiba Jelzést /$UDREI_i$ /) és választhatóan a 27. típusú, vagy a 28. típusú közlemény adatokat a σ_{UDRE} kiszámításához, úgy, hogy a 3.5.7.4.1 pontban lévő sértetlenségi követelmények kielégítésre kerüljenek. Amikor a gyors vagy a hosszútávú helyesbítések meghaladják azok kódolási tartományát, akkor az SBAS-nek jeleznie kell azt, hogy a műhold nem kielégítő műszaki állapotú /'egészségtelen'/ („Ne használja"). Amikor a $\sigma^2_{i,UDRE}$ nem meghatározható, akkor az SBAS-nek jeleznie kell, hogy a műhold „Nem-ellenőrzött".

Amikor a 6. típusú közlemény használatos a $\sigma^2_{i,UDRE}$ sugárzásához, akkor:

a) az $IODF_j$ –nek meg kell egyezni az abban a 'j' típusú közleményben vett gyors helyesbítés $IODF_j$ –vel, amelyre a $\sigma^2_{i,UDRE}$ alkalmazható; vagy

b) az $IODF_j$ –nek egyenlőnek kell lenni 3-al, ha a σ2i,UDRE az összes olyan vett gyors helyesbítési 'j' típusú közleményre alkalmazandó, amely nincs idő túllépésben.

3.5.7.4.6 *Teljesítőképesség csökkenési adat.* Az SBAS-nek teljesítőképesség csökkenési paramétereket kell sugározni (7. típusú közlemény) a gyors helyesbítésre alkalmazandó időzítési időköz közlésére, és annak biztosítására, hogy a 3.5.7.4.1 pontban meghatározott sértetlenségi követelmények kielégítésre kerüljenek.

3.5.7.5 *Pontos differenciál helyesbítési funkció.* Ha az SBAS pontos differenciál helyesbítési funkciót biztosít, akkor annak a 3.5.7.4 pontban leírt alap differenciál helyesbítési funkció követelményeihez kiegészítőleg az ebben a részben lévő követelményeknek is meg kell felelni.

3.5.7.5.1 *A pontos differenciál helyesbítési funkció teljesítménye.* Az aktív adatok bármilyen érvényes kombinációját véve, a tolerancián kívüli helyzet valószínűségének a vonatkozó idő-a-riasztásig értéknél hosszabb idő valószínűsége 2×10^{-7}-nél kevesebb kell, hogy legyen bármely megközelítés során egy nulla várakozási idejű felhasználót feltételezve. Az idő-a-riasztásig értéknek 5,2 másodpercnek kell lenni az olyan Műhold Bázisú Kiegészítő Rendszernél /SBAS/, amely precíziós megközelítéseket, vagy APV-II üzemeltetéseket támaszt alá, és 8 másodpercnél az olyan SBAS-nél, amely APV-I üzemeltetéseket támaszt alá. A tolerancián kívüli helyzetet úgy kell meghatározni, hogy az egy olyan vízszintes hiba, ami a Vízszintes Védelmi Szint Műhold Bázisú Kiegészítő Rendszer /HPL_{SBAS}/ értékeket, vagy függőleges hiba, ami a Függőleges Védelmi Szintet /VPL_{SBAS}/ meghaladja (ahogy az a 3.5.5.6 pontban meghatározásra került). Amikor egy tolerancián-kívüli helyzet kerül észlelésre, akkor a létrejövő riasztási közleményt (a 2.-tól 5.-ig terjedő és a 6., a 24., a 26. vagy a 27. típusú közleményekben sugározva) háromszor meg kell ismételni egy, a 4 másodpercen belüli, összesen négy alkalommal előforduló riasztási helyzet első bejelentése után.

1. Megjegyzés. - Az aktív adat egy olyan adatként került meghatározásra, amely nem idő-túllépéses a 3.5.8.1.1 pont szerint. Ez a követelmény műholdak helyzetsor rendszere(i)nek hibáját és a Műhold Bázisú Kiegészítő Rendszer /SBAS/ hibáját foglalja magába.

2. Megjegyzés. – Az egymást követő közleményeket a szabályos felfrissítési gyakorisággal lehet sugározni.

3.5.7.5.2 *Ionoszférikus rácspont (IGP) maszk.* A Műhold Bázisú Kiegészítő Rendszernek /SBAS/ sugároznia kell egy Ionoszférikus Rácspont /IGP/ maszkot és az Adatkibocsátás Ionoszférikus /$IODI_k$ /-t (11.-ig a 18. típusú közleményekben a 11 IGP sávnak megfelelően). Az IGP maszk értékeknek jelezni kell azt, hogy az egyes IGP-re adatok kerültek-e biztosításra, vagy sem. Ha az IGP 9. sáv használatos, akkor az IGP maszk értékeket az 55° N-től északra a 0.-tól a 8.-ig terjedő sávokban „0”-ra kell állítani. Ha a 10. sáv használatos, akkor az IGP maszk értékeket az 55° S-től délre a 0.-tól a 8.-ig terjedő sávokban „0”-ra kell állítani. Az Adatkibocsátás Ionoszférikus /$IODI_k$ /-t meg kell változtatni akkor, amikor egy változás áll be a k-dik sáv IGP maszk értékeiben. Az új IGP maszkot a 18. típusú közleményben kell sugározni, mielőtt az vonatkoztatva lenne a kapcsolatos 26. típusú közleményben. A 26. típusú közleményben lévő $IODI_k$ -nak egyenlőnek kell lenni azzal az IGP maszk közleményben (18. típusú közlemény) sugározott $IODI_k$ -val, ami annak az IGP-nek a kijelölésére használatos, amelyre az adat abban a közleményben biztosításra került.

3.5.7.5.2.1 **Ajánlás**. – *Amikor az IGP maszk megváltoztatásra kerül, akkor az SBAS-nek több alkalommal meg kell ismételnie a 18. típusú közleményt, mielőtt azt egy 26. típusú közleményben vonatkoztatná annak biztosítására, hogy a felhasználó részére biztosítva legyen az új maszk vétele. Ugyanazt az IODIk -t kell felhasználni az összes sávra.*

3.5.7.5.3 *Ionoszférikus helyesbítés.* Az SBAS-nek ionoszférikus helyesbítéseket kell sugározni az IGP maszkban kijelölt IGP-kre (IGP maszk értékek egyenlőek „1”-el).

3.5.7.5.4 *Ionoszférikus sértetlenségi adatok.* Azokra az IGP-kre, amelyekre helyesbítések kerülnek biztosításra, a Műhold Bázisú Kiegészítő Rendszernek /SBAS/ Hálózat Ionoszférikus Függőleges Hiba Jelzés /GIVEI/ adatokat kell sugározni úgy, hogy a 3.5.7.5.1 pontban leírt sértetlenségi követelmények kielégítésre kerüljenek. Ha az ionoszférikus helyesbítés vagy a $\sigma^2_{i,GIVE}$ túllépi a kódolási tartományát, akkor az SBAS-nek jeleznie kell azt, hogy az IGP nem megfelelő /’egészségtelen’/ (a helyesbítési adatokban kijelölve). Ha a $\sigma^2_{i,GIVE}$ -t nem lehet meghatározni, akkor az SBAS-nek jeleznie kell, hogy az IGP „Nem-ellenőrzött” (a GIVEI kódolásban kijelölve).

3.5.7.5.5 *Teljesítőképesség csökkenési adatok.* Az SBAS-nek sugároznia kell a teljesítőképesség csökkenési paramétereket (10. típusú közlemény) úgy, hogy a 3.5.7.5.1 pontban leírt sértetlenségi követelmények kielégítésre kerüljenek.

3.5.7.6 *Választható funkciók*

3.5.7.6.1 *Időmérési adatok.* Amikor Egyeztetett Világidő /UTC/ idő-paraméterek kerülnek sugárzásra, akkor azoknak a 3.5.4.8 pontban (12. típusú közlemény) meghatározottaknak kell lenni.

3.5.7.6.2 *Szolgáltatás jelzés*. Amikor szolgáltatás jelzési adatok kerülnek sugárzásra, akkor azoknak a 3.5.4.9 pontban (27. típusú közlemény) meghatározottaknak kell lenni, és a 28. típusú közleményt nem kell sugározni. Az összes 27. típusú közleményben az Adatkibocsátás Szolgáltatás /IODS/ számnak növekedni kell akkor, amikor változás van bármilyen 27. típusú közlemény adataiban.

3.5.7.6.3 *Óra – efemerisz kovariancia mátrix*. Amikor az óra – efemerisz kovariancia mátrix adatok sugárzásra kerülnek, akkor azokat az összes ellenőrzött műholdra sugározni kell úgy, ahogy az a 3.5.4.10 pontban meghatározásra került (28. típusú közlemény), és a 27. típusú közleményt nem szabad leadni.

3.5.7.7 *Ellenőrzés*

3.5.7.7.1 *A Műhold Bázisú Kiegészítő Rendszer /SBAS/ rádiófrekvenciás ellenőrzése*. Az SBAS-nek ellenőriznie kell a B-55. táblázatban megadott SBAS műhold paramétereket, és végre kell hajtani a jelzett tevékenységeket.

Megjegyzés. – Az ebben a részben lévő rádiófrekvenciás ellenőrzési követelményekhez kiegészítően szükséges az is, hogy speciális intézkedésekkel kerüljön ellenőrzésre a 3. fejezet 3.7.3.4.2.1.5 pontjában meghatározott pszeudo-távolság gyorsulás és a 3.5.2.2 pontban meghatározott vivőhullám fázis zaj, valamint a fenti 3.5.2.5 pontban leírt korrelációs veszteség, kivéve, ha elemzés és vizsgálatok kimutatják azt, hogy ezek a paraméterek nem tudják meghaladni a meghatározott határértékeket.

3.5.7.7.2 *Adat ellenőrzés*. Az SBAS-nek ellenőriznie kell a műhold jeleit azért, hogy megállapítsa az olyan helyzeteket, ami a légijármű fedélzeti vevők differenciális feldolgozásának helytelen működését fogja eredményezni a követési teljesítménnyel együtt, amely „D”- Melléklet 8.11 pontjában került meghatározásra.

3.5.7.7.2.1 A földi al-rendszernek a legerősebb kollerációs csúcsot kell használni az összes, a pszeudo-távolság helyesbítések létrehozására használatos vevőben.

3.5.7.7.2.2 A földi al-rendszernek meg kell határozni az olyan helyzeteket is, amely több, mint egy nulla átmenetet okoz azoknál a légijármű fedélzeti vevőknél, amelyek a „D”-Melléklet 8.11 pontjában meghatározottak szerinti Korai – Késői megkülönböztető funkciót használják.

3.5.7.7.2.3 Az ellenőrző tevékenységnél a Felhasználói Differenciál Távolságmérési Hibát /UDRE/ a műholdra a „Ne használja”-ra kell állítani.

3.5.7.7.2.4 Az SBAS-nek ellenőriznie kell az összes aktív adatot, amelyet a szolgáltatási területen belül lévő bármely felhasználó használhat.

3.5.7.7.2.5 Az SBAS-nek 5,2 másodpercen belül létre kell hozni egy riasztást akkor, ha az aktív adatok bármely kombinációja és a Globális Navigációs Műhold Rendszer /GNSS/ térbeli-jelei egy tolerancián-kívüli helyzetet eredményeznek a precíziós megközelítésre, vagy a II. Függőleges Vezetéses Megközelítésre /APV II./ (3.5.7.5.1).

3.5.7.7.2.6 Az SBAS-nek 8 másodpercen belül létre kell hozni egy riasztást akkor, ha az aktív adatok bármely kombinációja és a Globális Navigációs Műhold Rendszer /GNSS/ térbeli-jelei egy tolerancián-kívüli helyzetet eredményeznek az útvonal-repüléstől az I. Függőleges Vezetéses Megközelítésre /APV I./ (3.5.7.4.1).

Megjegyzés. – Az ellenőrzést az összes hibás állapotra alkalmazni kell, beleértve a műholdak helyzetsor rendszere(i)ben lévő hibákat, vagy a Műhold Bázisú Kiegészítő Rendszerű műholdak hibáit is. Ez az ellenőrzés alapfeltételként elfogadja azt, hogy a légijármű fedélzeti alkotóelemek kielégítik az RTCA/DO-229B követelményeit, kivéve azt, ahogy azt a 3.5.8 pont és a „D”- Melléklet 8.11 pontja hatálytalanítja.

3.5.7.8 *A műhold helyzetsor rendszer(ek) hibáinak hibatűrése*. Egy műhold helyzetsor rendszerű műhold rendellenességének előfordulásakor a Műhold Bázisú Kiegészítő Rendszernek /SBAS/ szabályszerűen folytatnia kell a működését azoknak a szabályos működésű műholdaknak a rendelkezésre álló jeleit felhasználva, amelyeket követni lehet.

3.5.8 LÉGIJÁRMŰ FEDÉLZETI ALKOTÓELEMEK

1. Megjegyzés. – Azok a paraméterek, amelyekre ebben a részben utalások találhatók, a 3.5.4 pont alatt kerültek meghatározásra.

2. Megjegyzés. – Az ebben a részben leírt követelmények egy részét nem lehet az olyan berendezésekre alkalmazni, amelyek kiegészítő navigációs érzékelőket foglalnak magukba, mint például egy berendezést, ami integrálja az SBAS-t az inerciális navigációs érzékelőkkel.

3.5.8.1 *SBAS-alkalmasságú Globális Navigációs Műhold Rendszer /GNSS/ vevő*. Kivéve azt, ahol határozottan megjegyzésre kerül, az SBAS- alkalmasságú GNSS vevőnek fel kell dolgoznia az SBAS jeleit, és meg kell felelnie a 3.1.3.1 pontban (GPS vevő) és/vagy a 3.2.3.1 pontban (GLONASS vevő) leírt követelményeknek. Az egyes műholdakra vonatkozó pszeudo-távolság méréseket a vivőhullám mérések és egy olyan simító szűrő felhasználásával kell simítani, amelynek az eltérése 0,1 méternél kevesebb 200 másodpercen belül az indulási állapot után, a szűrőnek a 3.6.5.1 pontban meghatározott állandósult átviteléhez viszonyítva, egy, a kód fázis és az integrált vivőhullám fázis közötti eltérés jelenlétében 0,01 méter/másodperc értékig.

3.5.8.1.1 *Az adat felhasználás feltételei*. A vevőnek egy SBAS közleményből származó adatokat csak akkor kell felhasználni, amikor ezeknek a közleményeknek a Ciklikus Redundancia Ellenőrzése /CRC/ megerősítésre került. Az egy SBAS műholdtól jövő 0. típusú közlemény vétele annak a műholdnak a leválasztását kell, hogy létrehozza, és az attól a műholdtól eredő összes adatot legalább 1 percig érvényteleníteni kell. A GPS műholdakra a vevőnek csak akkor kell alkalmazni a hosszútávú helyesbítéseket, ha az Adatkibocsátás /IOD/ megegyezik mind az Adatkibocsátás efemerisszel /IODE/, mind az Adatkibocsátás órának /IODC/ a 8 legkisebb helyértékű bitjével. A GLONASS műholdakra a vevőnek csak akkor kell alkalmazni a hosszútávú helyesbítéseket, ha a GLONASS efemerisz vételének ideje (t_r) belül van a következő IOD érvényességi időközében, ahogy az a 3.5.4.4.1 pontban meghatározásra került:

$$t_{LT} – L – V \le t_r \le t_{LT} – L$$

Megjegyzés. – Ez a követelmény nem foglalja magába azt, hogy a vevőnek abba kell hagyni az SBAS műhold követését.

3.5.8.1.1.1 A vevőnek csak akkor kell a sértetlenségi, vagy helyesbítési adatokat felhasználni, ha az ahhoz az adathoz kapcsolódó Adatkibocsátás, Ál-véletlen zaj /IODP/ megegyezik az Ál-véletlen zaj /PRN/ maszkhoz kapcsolódó IODP-vel.

3.5.8.1.1.2 A vevőnek csak akkor kell az SBAS biztosítású ionoszférikus adatokat (Ionoszférikus Rácspont /IGP/ számított függőleges késés és Hálózat Ionoszférikus Függőleges Hiba Jelzés /$GIVEI_i$ /) felhasználni, ha a 26. típusú közleményben lévő Adatkibocsátás – Ionoszférikus /$IODI_k$ /-hoz kapcsolódó adatok megegyeznek a 18. típusú közleményben továbbított vonatkozó Ionoszférikus Rácspont /IGP/ sáv maszkkal.

3.5.8.1.1.3 A vevőnek fel kell használni azokat a legújabb vett sértetlenségi adatokat, amelyekre az Adatkibocsátás–Gyors Helyesbítés /$IODF_j$ / 3-al egyenlő, vagy az $IODF_j$ megegyezik az alkalmazott gyors helyesbítési adatokhoz kapcsolódó $IODF_j$ -vel (ha helyesbítések biztosításra kerülnek).

3.5.8.1.1.4 A vevőnek fel kell használni minden körzeti teljesítőképesség csökkenést a $\sigma^2{}_{i,UDRE}$ –re, ahogy azt a 27. típusú szolgáltatási közlemény meghatározza. Amikor egy 27. típusú közlemény egy új Adatkibocsátás – Szolgáltatás /IODS/ egy magasabb δUDRE-t jelez a felhasználó helyén, akkor azonnal a magasabb δUDRE-t kell alkalmazni. Egy 27. típusú közleményben lévő alacsonyabb δUDRE-t nem szabad alkalmazni addig, amíg a közlemények egy teljes sorozata az új IODS-el vételre nem került.

3.5.8.1.1.5 A vevőnek alkalmaznia kell a műhold fajlagos teljesítőképesség csökkenést a $\sigma_{i,UDRE}{}^2$ –re úgy, ahogy az a 28. típusú óra – efemerisz kovariancia mátrix közlemény által meghatározott. A 28. típusú közleményből származtatott δ_{UDRE}-t azonnal alkalmazni kell.

3.5.8.1.1.6 A Globális Helymeghatározó Rendszer /GPS/ műholdjaira a vevőnek csak akkor kell a hosszútávú helyesbítéseket alkalmazni, ha az Adatkibocsátás /IOD/ megegyezik mind az Adatkibocsátás – Efemerisszel /IODE/, mind az Adatkibocsátás – Óra /IODC/ 8. Legkisebb Helyértékű Bitjével.

Megjegyzés. – A Műhold Bázisú Kiegészítő Rendszerű /SBAS/ műholdaknál nincs olyan mechanizmus, ami összekapcsolja a Geostacionárius Pálya /GEO/ távolság-meghatározási funkció adatait (9. típusú közlemény) és a hosszútávú helyesbítéseket.

3.5.8.1.1.7 Egymást követő négy SBAS közlemény elvesztése esetén a vevő a továbbiakban nem támaszthatja alá az SBAS-en alapuló precíziós megközelítési, vagy függőleges vezetéses megközelítési /APV/ üzemeltetéseket.

3.5.8.1.1.8 A vevő nem használhat fel egy sugárzott adat paramétert, miután az a B-56. táblázatban meghatározottaknak megfelelően ’idő-túllépéses’.

B-56. táblázat: Adat idő-túllépési időközök

Adat	Kapcsolatos közlemény típus	Útvonal, Közelkörzet, Nem-precíziós megközelítés /NPA/ idő-túllépés	Precíziós megközelítés, Függőleges Vezetéses megközelítés /APV/ idő-túllépés
Óra – efemerisz kovariancia mátrix	28	360	240
Műhold Bázisú Kiegészítő Rendszer /SBAS/ teszt üzemmódban	0	Nem alkalmazható.	Nem alkalmazható.
Ál-véletlen zaj /PRN/ maszk	1	600 s	600 s
Felhasználói Differenciál Távolságmérési Hiba Jelzés /UDREI/	2.-tól 6.-ig terjedő, 24.	18 s	12 s
Gyors helyesbítések	2.-tól 5.-ig terjedő, 24.	(lásd a B-57. táblázatot)	(lásd a B-57. táblázatot)
Hosszútávú helyesbítések	24., 25.	360 s	240 s
Geostacionárius Pálya /GEO/ távolságmérési funkció adatok	9.	360 s	240 s
Gyors helyesbítés teljesítőképesség csökkenés	7.	360 s	240 s
Teljesítmény-csökkenési paraméterek	10.	360 s	240 s
Ionoszférikus rács maszk	18.	1 200 s	1 200 s
Ionoszférikus helyesbítések, Ionoszférikus Rács Függőleges Hiba Jelzés /GIVEI/	26.	600 s	600 s
Időmérési adatok	12.	86 400 s	86 400 s
Naptár adatok	17.	Nincs	Nincs
Szolgáltatási szint	27.	86 400 s	86 400 s

Megjegyzés: Az idő-túllépési időközök egy közlemény vételének befejezésétől vannak meghatározva.

B-57. táblázat: A gyors helyesbítés idő-túllépés időközök kiértékelése

Gyors helyesbítés teljesítőképesség csökkenési tényező jelzés (ai_i)	Nem-precíziós megközelítés /NPA/ idő-túllépési időköz a gyors helyesbítésre (I_{fc})	Precíziós megközelítés /PA/ idő-túllépési időköz a gyors helyesbítésre (I_{fc})
0	180 s	120 s
1	180 s	120 s
2	153 s	102 s
3	135 s	90 s
4	135 s	90 s

8	63 s	42 s
9	45 s	30 s
10	45 s	30 s
11	27 s	18 s
12	27 s	18 s
13	27 s	18 s
14	18 s	12 s
15	18 s	12 s

3.5.8.1.1.9 A vevő nem használhat fel egy gyors helyesbítést, ha a Távolság-meghatározási változás helyesbítéshez /RRC/ kapcsolódó Δt meghaladja a gyors helyesbítések időzítési időközét, vagy ha az RRC 'kora' meghaladja a 8Δt -t.

3.5.8.1.1.10 A Távolság-meghatározási változás helyesbítés /RRC/ számítását újra-inicializálni kell, ha egy „Ne használja", vagy a „Nem-ellenőrzött" jelzést veszik a műholdra.

3.5.8.1.1.11 Az SBAS-re alapozott precíziós megközelítéses, vagy Függőleges Vezetéses Megközelítéses /APV/ üzemeltetésekhez, a vevő csak olyan műholdakat használhat fel, amelyeknek a magassági szöge 5 fokos, vagy annál nagyobb.

3.5.8.1.1.12 A vevő a továbbiakban nem támaszthat alá SBAS-re alapozott precíziós megközelítéses, vagy APV megközelítéses üzemeltetéseket egy meghatározott műholdat felhasználva, ha a vett Felhasználói Differenciál Távolságmérési Hiba Jelzés /$UDREI_i$ / nagyobb, vagy egyenlő 12-nél.

3.5.8.2 *Távolságmérési funkció*

3.5.8.2.1 *Precíziós megközelítési és Függőleges vezetéses megközelítési üzemeltetések.* Egy SBAS műhold helyesbített pszeudo-távolság hibájában a teljes légijármű fedélzeti járulékos hiba négyzetes középértéke (1 szigma) a minimális vett jel teljesítmény szintnél (3. fejezet, 3.7.3.4.4.3) a legrosszabb interferencia környezet esetén - ahogy az a későbbiekben a 3.7 pontban meghatározásra került – egyenlő, vagy kevesebb kell, hogy legyen, mint 1,8 méter, a többutas hatásokat, a troposzférikus és az ionoszférikus megmaradó hibákat kizárva.

Megjegyzés. – A légijármű fedélzeti alkotóelemek összekapcsolják a többutas és a troposzféra által létrehozott hibákat (3.5.8.4.1). A szolgáltatás előrejelzése céljából, a többutas hibára elfogadott, hogy az 0,6 méternél (1 szigma) kevesebb.

3.5.8.2.2 *Indulási, útvonal, közelkörzeti és nem-precíziós megközelítési üzemeltetések*. Egy SBAS műhold helyesbített pszeudo-távolság hibájában a teljes légijármű fedélzeti járulékos hiba négyzetes középértéke (1 szigma) a minimális vett jel teljesítmény szintnél (3. fejezet, 3.7.3.4.4.3) a legrosszabb interferencia környezet esetén - ahogy az a későbbiekben a 3.7 pontban meghatározásra került – egyenlő, vagy kevesebb kell, hogy legyen, mint 5 méter, a többutas hatásokat, a troposzférikus és az ionoszférikus megmaradó hibákat kizárva.

3.5.8.2.3 *A Műhold Bázisú Kiegészítő Rendszerű /SBAS/ műhold helyzete*

3.5.8.2.3.1 *Helyzet számítás*. A vevőnek dekódolni kell a 9. típusú közleményt és meg kell határoznia az SBAS műhold kód fázis eltolását és helyzetét (X_G , Y_G , Z_G).

3.5.8.2.3.2 *SBAS műhold azonosítás*. Az SBAS műholdakat a vevőnek kell megkülönböztetni.

Megjegyzés. – Ezt a követelményt kell egy műholdnak a kereszt-korreláció miatti hibás adatgyűjtésére alkalmazni.

3.5.8.2.4 *Naptár adatok*

3.5.8.2.4.1 **Ajánlás**. – *Az SBAS által biztosított naptár adatokat fel lehet használni az adatgyűjtésre.*

Megjegyzés. – A Geostacionárius Pálya /GEO/ naptár adatokban biztosított működési állapot /'egészség'/ és állapot információk alátámasztják az adatgyűjtést, de ezeket nem kell felhasználni úgy, mint az arra a műholdnak a használatára vonatkozó feltételt.

3.5.8.3 *Globális Navigációs Műhold Rendszer /GNSS/ műhold állapot funkció*. A vevőnek ki kell zárni a helyzet megoldásból a műholdakat akkor, ha azok az SBAS által „Ne használja"-ként vannak azonosítva. Amikor SBAS-biztosítású sértetlenség használatos, akkor a vevőtől nem kívánható el az, hogy kizárja az olyan Globális Helymeghatározó Rendszer /GPS/ műholdakat, amelyek GPS-biztosítású efemerisz működési állapot jelzésen alapulnak, ahogy az a 3.1.3.1.1 pont szerint szükséges, vagy az, hogy kizárja az olyan GLONASS műholdakat, amelyek GLONASS-biztosítású efemerisz működési állapot jelzésen alapulnak, ahogy az a 3.2.3.1.1 pont szerint szükséges.

1. Megjegyzés. – Egy műhold helyzetsor rendszer(ek) működési állapot jelzés szerint rossz működési állapotúként kijelölt műhold esetében az SBAS képes lehet arra, hogy olyan efemerisz és óra helyesbítéseket sugározzon, ami a felhasználó részére lehetővé fogja tenni azt, hogy folytassa a műhold felhasználását.

2. Megjegyzés. – Amikor az SBAS által „Nem-ellenőrzött"-ként azonosított műholdak használatosak a helyzet megoldáshoz, akkor az SBAS nem biztosítja a sértetlenséget. A Légijármű Bázisú Kiegészítő Rendszert /ABAS/, vagy a Földi Fázisú Kiegészítő Rendszert /GBAS/ fel lehet használni a sértetlenség biztosításához, ha rendelkezésre áll.

3.5.8.4 *Alap és precíz differenciál funkciók*

3.5.8.4.1 *Műhold helyzetsor rendszer(ek) távolságmérési pontossága*. Egy GPS műhold helyesbített pszeudo-távolság hibájában a teljes légijármű fedélzeti járulékos hiba négyzetes középértéke (1 szigma) a minimális vett jel teljesítmény szintnél (3. fejezet, 3.7.3.1.5.4) a legrosszabb interferencia környezet esetén - ahogy az a későbbiekben a 3.7 pontban meghatározásra került – egyenlő, vagy kevesebb kell, hogy legyen, mint 0,4 méter, a többutas hatásokat, a troposzférikus és az ionoszférikus megmaradó hibákat kizárva. Egy GLONASS műholdra a helyesbített pszeudo-távolság hibában a teljes légijármű fedélzeti járulékos hiba négyzetes középértéke /RMS/ a minimális vett jel teljesítmény szintnél (3. fejezet 3.2.5.4 pont) a legrosszabb interferencia környezet esetén – ahogy az a 3.7 pontban meghatározásra került – egyenlő, vagy kevesebb kell, hogy legyen 0,8 méternél, a többutas terjedési hatásokat, a troposzférikus és ionoszférikus megmaradó hibákat kizárva.

3.5.8.4.2 Precíziós *megközelítési és Függőleges vezetéses megközelítési /APV/ üzemeltetések*

3.5.8.4.2.1 A vevőnek ki kell számítani és fel kell használni a hosszútávú helyesbítéseket, a gyors helyesbítéseket, a távolság meghatározási változás helyesbítéseket és a sugárzási ionoszférikus helyesbítéseket. A GLONASS műholdakra a Műhold Bázisú Kiegészítő Rendszertől /SBAS/ vett ionoszférikus helyesbítéseket meg kell szorozni a GLONASS – GPS frekvenciák arányának $(f_{GLONASS}/f_{GPS})^2$ négyzetével.

3.5.8.4.2.2 A vevőnek egy általános-legkisebb-négyzetek helyzet megoldást kell alkalmazni.

3.5.8.4.2.3 A vevőnek egy olyan troposzférikus modelt kell alkalmazni, hogy a pszeudo-távolság megmaradó értékének a középértéke (μ) 0,15 méternél kevesebb legyen, és az 1 szigma eltérés 0,07 méternél kevesebb legyen.

Megjegyzés. – Egy, az ezt a követelményt kielégítő model kidolgozásra került. Az útmutató anyag a „D”-Melléklet 6.7.3 pontjában került megadásra.

3.5.8.4.2.4 A vevőnek ki kell számítani és alkalmaznia kell a 3.5.5.6 pontban meghatározott vízszintes és függőleges védelmi szintet. Ebben a számításban a σ_{tropo} -nak a következőnek kell lenni:

$$\frac{1}{\sqrt{0.002+\sin^2(\theta_i)}}\times 0.12\text{ m}$$

ahol θ_i az i-dik műhold magassági szöge.

Azonkívül a σ_{air} -nek ki kell elégíteni azt a feltételt, hogy egy nulla középértékű szabvány eloszlás és egy, a σ_{air} -el egyenlő szabvány eltérés a légijármű fedélzeti pszeudo-távolság megmaradó hibáját az alábbiak szerint kapcsolja a hibaeloszláshoz:

$$\int_y^{\infty} f_n(x)dx \le Q\left(\frac{y}{\sigma}\right) \quad \text{az összes } \frac{y}{\sigma} \ge 0 \text{ -ra és}$$

$$\int_{-\infty}^{-y} f_n(x)dx \le Q\left(\frac{y}{\sigma}\right) \quad \text{az összes } \frac{y}{\sigma} \ge 0 \text{ -ra}$$

ahol:

$f_n(x)$ = a légijármű fedélzeti megmaradó pszeudo-távolság hibájának a valószínűségi sűrűség funkciója és

$$Q(x) = \frac{1}{\sqrt{2\pi}}\int_x^{\infty} e^{-\frac{t^2}{2}}dt$$

Megjegyzés. – A légijármű fedélzeti többutas terjedésre a 3.6.5.5.1 pontban meghatározott szabvány elhanyagolási tényezőt lehet felhasználni a többutas terjedési hibák összekapcsolására.

3.5.8.4.2.5 A precíziós megközelítési és a Függőleges Vetetéses Megközelítési /APV/ üzemeltetésekre a 17. típusú közleményben sugárzott szolgáltatás biztosító azonosítónak /ID/ meg kell egyezni a Végső Megközelítési Szakasz /FAS/ adatblokkban lévő szolágáltatás biztosító azonosítóval, kivéve, ha a FAS adatblokkban az Azonosító /ID/ 15-el egyenlő.

Megjegyzés. – A Műhold Bázisú Kiegészítő Rendszerre /SBAS/ a Végső Megközelítési Szakasz /FAS/ adatblokkok a légijármű fedélzeti adatbázisokban vannak tárolva. Az adat formátum a ciklikus redundancia elenőrzéses érvényesítéshez a "D"- Melléklet 6.6 pontjában került bemutatásra. Ez eltér a Földi Bázisú Kiegészítő Rendszer /GBAS/ Végső Megközelítési Szakasz /FAS/ adatblokkra a 3.6.4.5 pontban megadottaktól, amelyben a Műhold Bázisú Kiegészítő Rendszer /SBAS/ Vízszintes Riasztási Határértékeket /HAL/ és a Függőleges Riasztási Határértékeket /VAL/ foglalja magába egy adott megközelítési eljárásra. Az SBAS pszeudo-távolság helyesbítéseit felhasználva végrehajtott megközelítésekre, a FAS adatblokkban lévő szolgáltatás biztosító azonosító /ID/ ugyanaz, mint ami a 17. típusú közleményben a működési állapot /'egészség'/ és állapot információ részeként sugárzott szolgáltatás biztosító azonosító. Amikor a Végső Megközelítési Szakasz /FAS/ adatblokkjában a szolgáltatás biztosító azonosító /ID/ 15-el egyenlő, akkor bármelyik szolgáltatás biztosítót fel lehet használni. Amikor a Végső Megközelítési Szakasz /FAS/ adatblokkjában a szolgáltatás biztosító azonosító /ID/ 14-el egyenlő, akkor a Műhold Bázisú Kiegészítő Rendszer /SBAS/ precíz differenciál helyesbítéseit nem lehet a megközelítéshez felhasználni.

3.5.8.4.3 *Indulási, útvonal, közelkörzeti és nem-precíziós megközelítési üzemeltetések*

3.5.8.4.3.1 A vevőnek ki kell számítani és fel kell használni a hosszútávú helyesbítéseket, a gyors helyesbítéseket és a távolság meghatározási változás helyesbítéseket.

3.5.8.4.3.2 A vevőnek ki kell számítani és fel kell használni az ionoszférikus helyesbítéseket.

Megjegyzés. – Az ionoszférikus helyesbítések kiszámításának módszerei a 3.1.2.4 és 3.5.5.5.2 pontokban kerültek biztosításra.

3.5.8.4.3.3 A vevőnek egy olyan troposzférikus modelt kell alkalmazni, hogy a pszeudo-távolság megmaradó értékének a középértéke (μ) 0,15 méternél kevesebb legyen, és a szabvány eltérés 0,07 méternél kevesebb legyen.

Megjegyzés. – Egy, az ezt a követelményt kielégítő model kidolgozásra került. Az útmutató anyag a "D"- Melléklet 6.7.3 pontjában került megadásra.

3.5.8.4.3.4 A vevőnek ki kell számítani és alkalmaznia kell a 3.5.5.6 pontban meghatározott vízszintes és függőleges védelmi szintet. Ebben a számításban a σ_{tropo} -nak a következőnek kell lenni:

$$\frac{1}{\sqrt{0.002+\sin^2(\theta_i)}}\times 0.12 \text{ m}$$

ahol θ_i az i-dik műhold magassági szöge.

Azonkívül a σ_{air} -nek ki kell elégíteni azt a feltételt, hogy egy nulla középértékű normál eloszlás és egy, a σ_{air} -el egyenlő szabvány eltérés a légijármű fedélzeti pszeudo-távolság megmaradó hibáját az alábbiak szerint kapcsolja a hibaeloszláshoz:

$$\int_y^{\infty} f_n(x)dx \le Q\left(\frac{y}{\sigma}\right) \text{ az összes } \frac{y}{\sigma} \ge 0 \text{ -ra és}$$

$$\int_{-\infty}^{-y} f_n(x)dx \le Q\left(\frac{y}{\sigma}\right) \quad \text{az összes } \frac{y}{\sigma} \ge 0 \text{ -ra}$$

ahol:

f_n (x) = a valószínűségi sűrűség funkciója a légijármű fedélzeti megmaradó pszeudo-távolság hibájának és

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} e^{-\frac{t^2}{2}} dt$$

Megjegyzés. – A légijármű fedélzeti többutas terjedésre a 3.6.5.5.1 pontban meghatározott szabvány elhanyagolási tényezőt lehet felhasználni a többutas terjedési hibák összekapcsolására.

3.5.8.4.4 **Ajánlás**. – *Az indulási, útvonal, közelkörzeti és nem-precíziós megközelítési üzemeltetésekhez, a vevő felhasználhatja a sugárzott ionoszférikus helyesbítéseket, amikor az rendelkezésre áll, és egy olyan troposzférikus modelt, amelynek a teljesítménye egyenlő avval, ami a 3.5.8.4.3 pontban előírásra került.*

3.5.9 A MŰHOLD BÁZISÚ KIEGÉSZÍTŐ RENDSZEREK /SBAS/ KÖZÖTTI INTERFÉSZ (KAPCSOLAT)

Megjegyzés. –A különböző SBAS szolgáltatás biztosítók közötti interfészre vonatkozó útmutató anyag a "D"- Melléklet 6.3 pontjában került megadásra.

3.6 Földi Bázisú Kiegészítő Rendszer /GBAS/

Megjegyzés. – Ebben a részben, hacsak nincs külön kiemelve, a megközelítés függőleges vezetéssel (APV) APV-I és APV-II jelentéssel bír.

3.6.1 ÁLTALÁNOS RÉSZ

A Földi Bázisú Kiegészítő Rendszernek /GBAS/ egy földi al-rendszerből és egy légijármű fedélzeti al-rendszerből kell felépülni. A GBAS földi al-rendszereinek a Globális Navigációs Műhold Rendszer /GNSS/ távolság-meghatározási jeleihez adatokat és helyesbítéseket kell biztosítani egy digitális VHF adat sugárzással a légijármű fedélzeti al-rendszer részére.

Megjegyzés. – Az útmutató anyag a "D"- Melléklet 7.1 pontjában került megadásra.

3.6.2 RÁDIÓFREKVENCIÁS (RF) JELLEMZŐK

3.6.2.1 *Vivőhullám frekvencia stabilitás.* Az adat sugárzás vivőhullám frekvenciáját a kijelölt frekvenciához ±0,0002 százalékon belül kell tartani.

3.6.2.2 *Bit – fázis -változás kódolás.* A Földi Bázisú Kiegészítő Rendszer /GBAS/ közleményeit szimbólumokká kell összeállítani, amelyek mindegyike 3 egymást követő közlemény bitből áll. A közlemény végét 1, vagy 2 töltő bittel kell kitölteni, ha ez szükséges ahhoz, hogy a közlemény utolsó 3-bites szimbólumát kialakítsa. A szimbólumokat D8PSK vivőhullám fázis eltolássá ($\Delta\phi_k$) kell átalakítani a B-57. táblázatban megadottaknak megfelelően.

Megjegyzés. – A vivőhullám fázist a k-dik szimbólumra (ϕ_k) adja meg:

$$\phi_k = \phi_{k-1} + \Delta\phi_k$$

3.6.2.3 *Modulációs hullámforma és impulzusformáló szűrők.* A differenciál fázis kódoló kimenetet egy olyan impulzusformáló szűrővel kell szűrni, amelynek a kimenete, az s(t), a következők szerint írható le:

$$s(t) = \sum_{k=-\infty}^{k=\infty} e^{j\phi_k} h\,(t - kT)$$

ahol:

h = a felfutó koszinusz szűrő impulzus válasza;
ϕ_k = (ahogy a 3.6.2.2 pontban meghatározásra került);
t = idő; és
T = az egyes szimbólumok időtartama = 1/10 500 másodperc.

Ennek az impulzusformáló szűrőnek a névleges komplex frekvencia jelleggörbéje egy felfutó koszinusz α = 0,6 kell, hogy legyen. A felfutási idő, h(t), és a frekvencia jelleggörbe, H(f), az alapsáv szűrőkön a következő lesz:

$$h(t) = \frac{\sin\left(\frac{\pi t}{T}\right)\cos\left(\frac{\pi\alpha t}{T}\right)}{\frac{\pi t}{T}\left[1-\left(\frac{2\alpha t}{T}\right)^2\right]}$$

$$H(f) = \begin{cases} 1 & \text{az} \quad 0 \le f < \frac{1-\alpha}{2T} \quad \text{- re} \\ \frac{1-\sin\left(\frac{\pi}{2\alpha}(2fT-1)\right)}{2} & \text{az} \quad \frac{1-\alpha}{2T} \le f \le \frac{1+\alpha}{2T} \quad \text{- re} \\ 0 & \text{az} \quad f > \frac{1+\alpha}{2T} \quad \text{- re} \end{cases}$$

Az impulzusformáló szűrő kimenetének, s(t), kell a vivőhullámot modulálni.

3.6.2.4 *Hiba vektor nagyság.* A továbbított jel hiba vektor nagyságának 6,5 százalék négyzetes középértéknél (1 szigma) kisebbnek kell lenni.

3.6.2.5 *Rádiófrekvenciás adatátviteli sebesség.* A szimbólum átviteli sebességnek másodpercenként 10 500 szimbólum ± 0,005 százaléknak kell lenni, ami egy névleges 31 500 bit/másodperc átviteli sebességet eredményez.

B-58. táblázat: Adat kódolás

Közlemény bitek			Szimbólum fázis eltolás
I_{3k-2}	I_{3k-1}	I_{3k}	$\Delta\phi_k$
0	0	0	$0\pi/4$
0	0	1	$1\pi/4$
0	1	1	$2\pi/4$
0	1	0	$3\pi/4$
1	1	0	$4\pi/4$
1	1	1	$5\pi/4$
1	0	1	$6\pi/4$
1	0	0	$7\pi/4$

Megjegyzés. – Az I_j a sugározandó szinkron vezérjel j-dik bitje, ahol az I_1 az impulzussorozat első bitje.

3.6.2.6 *Sugárzás a kijelöletlen időrésekben*. Minden üzemeltetési körülmény esetén a maximális teljesítmény egy, a kijelölt frekvencián központosuló 25 kHz-es csatorna sebességen keresztül, amikor bármely kijelöletlen időrésben kerül mérésre, nem haladhatja meg a –105 dBc-t az engedélyezett adó teljesítményére vonatkoztatva.

Megjegyzés. – Ha az engedélyezett adó teljesítmény nagyobb, mint 150W, a -105 dBc lehet, hogy nem nyújt védelmet olyan időrésben történő sugárzások vétele ellen, mely másik szükséges adó számára van kijelölve olyan vevők részére, melyek a nemkívánt sugárzó antennától 200m-es távolságon belül vannak.

3.6.3 ADAT SZERKEZET

3.6.3.1 *Adó időzítés*

3.6.3.1.1 *Az adat sugárzás időzítési szerkezete*. Az időosztásos többszörös elérés (TDMA) időzítési szerkezetét a keretekre és az időrésekre kell alapozni. Az egyes kereteknek időtartamban 500 milliszekundumnak kell lenni. 2 ilyen keretet kell magába foglalnia minden egyes 1-másodperces Egyeztetett Világidő /UTC/ korszaknak. Ezekből a keretekből az elsőnek az UTC korszak kezdeténél kell kezdődni és a második keretnek az UTC korszak kezdete után 0,5 másodperccel kell elkezdődnie. A keretnek időosztásos multiplexnek kell lenni úgy, hogy annak 8 különálló (A-tól H-ig) 62,5 milliszekundumos időtartamú időrésből kell állni.

3.6.3.1.2 *Szinkron vezér jelek*. Az egyes kijelölt időréseknek legalább 1 szinkron vezér jelet kell magukba foglalni. Az időrés alkalmazásának elindításához a Földi Bázisú Kiegészítő Rendszernek /GBAS/ egy szinkron vezér jelet kell sugározni abban az időrésben, amely minden egyes 5 egymást követő keretnél van. Az egyes alkalmazott időrésekre a földi al-rendszernek egy szinkron vezér jelet kell sugározni minden egyes egymást követő 5 keretnél legalább 1 keretben.

1. Megjegyzés. – A szinkron vezér jelek egy, vagy több közleményt foglalnak magukba, és változó hosszúságúak lehetnek az időrések közötti maximális megengedett hosszig, ahogy azt a 3.6.3.2 pont megkívánja.

2. Megjegyzés. – Az időrés indítása során a légijármű fedélzeti vevő nem veheti az első négy szinkron vezérlő jelet.

3.6.3.1.3 *Időzítési előirányzat a szinkron vezérlő jelekhez*

3.6.3.1.3.1 Az egyes szinkron vezérlő jeleket egy 62,5 milliszekundumos időrésbe kell belefoglalni.

3.6.3.1.3.2 A szinkron vezérlő jel kezdetének az időrés kezdete után 95,2 mikroszekundumnál kell bekövetkezni, ± 95,2 mikroszekundum toleranciával.

3.6.3.1.3.3 A GBAS/E berendezésnél a szinkron vezérlő jel szinkronizáló és a bizonytalanság feloldó része kezdetének a vízszintes polarizációval (HPOL) együtt továbbítva 10 mikroszekundumon belül kell bekövetkezni, a függőleges polarizációval (VPOL) sugárzott szinkron vezérlő jel kezdetéhez viszonyítva.

Megjegyzés. – A B-59. táblázat mutatja be a szinkron vezérlő jel időzítését.

3.6.3.1.4 *Felfutás és adó teljesítmény stabilizálás*. Az adónak a tartós teljesítmény szintjének 90 százalékára a szinkron vezérlő jel kezdete után (2 szimbólum) 190,5 mikroszekundumon belül fel kell futni. Az adónak a szinkron vezér jel kezdete után (5 szimbólum) 476,2 mikroszekundumon belül állandósítania kell a tartós teljesítmény szintjét.

Megjegyzés. – Az adó teljesítmény állandósítási időtartamot a légijármű fedélzeti vevője felhasználhatja az automatikus erősítés szabályozása beállításához.

3.6.3.1.5 *Lefutás*. Azután, hogy egy kijelölt időrésben az utolsó információs szimbólum továbbításra került, az adó kimenő teljesítmény szintjének le kell csökkenni legalább 30 dB-el 285,7 mikroszekundumon (3 szimbólum) belül a tartós teljesítmény szintje alá.

3.6.3.2 *A szinkron vezér jel szervezése és kódolása*. Az egyes szinkron vezérlő jeleknek a B-60. táblázatban bemutatott adat elemekből kell állni. A közlemények kódolásának a következő sorrendet kell követni: alkalmazási adat formázás, impulzussorozat vevő oldali hibajavítás (FEC) generálás, alkalmazási vevő oldali hibajavítás (FEC) generálás és bit keverés.

3.6.3.2.1 *Szinkronizálás és bizonytalanság feloldás*. A szinkronizáló és bizonytalanság feloldó mezőnek az alábbiakban bemutatott 48-bites sorozatból kell állni úgy, hogy jobbról a legszélső biteket kell először leadni:

010 001 111 101 111 110 001 100 011 101 100 000 011 110 010 000

B-59. táblázat: Szinkron vezér jel időzítés

Esemény	Névleges esemény időtartam	A tartós teljesítmény névleges százaléka
Felfutás	190,5 μs	0-tól 90 %-ig
Adó teljesítmény stabilizálás	285,7 μs	90-től 100 %-ig
Szinkronizáció és bizonytalanság feloldás	1 523,8 μs	100 %
A kevert adatok továbbítása	58 761,9 μs	100 %
Lefutás	285,7 μs (1.Megjegyzés)	100-tól 0 %-ig

MEGJEGYZÉSEK. –
1. A kevert adatok továbbítására feltüntetett esemény időtartam az 1 776 bites maximális alkalmazási adat hosszra, 2 feltöltő bitre és a névleges szimbólum időtartamra vonatkozik.

2. Ezek az időzítési követelmények egy névleges szimbólum időtartamra 1 262 mikroszekundomos terjedési védettségi időt biztosítanak, ami egy körülbelül 370 km-es
(200 tengeri mérföld) egyirányú terjedési távolságot vesz figyelembe.

3. Ahol egy GBAS sugárzó antennából jövő szinkron vezér jelet lehet venni több, mint 370 km (200 tengeri mérföld) távolságból, ami nagyobb, mint a szomszédos időrést használó másik sugárzó antenna távolsága, hosszabb védelmi időre van szükség mindkét szinkron jel elvesztésének elkerüléséhez. A hosszabb védelmi idő biztosításához az első szinkron jel alkalmazási adat hosszúságának 1744 bitre való korlátozására van szükség. Ez különbséget tesz lehetővé akár 692 km (372 tengeri mérföld) távolságra történő terjedésnél, konfliktus nélkül.

B-60. táblázat: A szinkron vezér jel adattartalma

Alkotóelem	Adattartalom	A bitek száma
A szinkron vezér jel kezdete	Mind nulla	15
Teljesítmény stabilizálás		
Szinkronizálás és bizonytalanság feloldás	3.6.3.2.1	48
Kevert adatok:	3.6.3.3	
Állomás időrés azonosító (SSID)	3.6.3.3.1	3
Továbbítási hossz	3.6.3.3.2	17
Impulzus-sorozat vevő oldali hibajavítás /FEC/	3.6.3.3.3	5
Alkalmazási adat	3.6.3.3.4	1 776-ig
Alkalmazási vevő oldali hibajavítás /FEC/	3.6.3.3.5	48
Feltöltő bitek (Megjegyzés)	3.6.2.2	0-tól 2-ig

Megjegyzés. – A feltöltő bitek adat keverése választható (3.6.3.3.6).

3.6.3.3 *A kevert adatok tartalma*

3.6.3.3.1 *Állomás időrés azonosító (SSID).* Az állomás időrés azonosítónak /SSID/ annak a számszerinti értéknek kell lenni, ami a földi referencia állomás részére az első időrésre kijelölt A-tól H-ig terjedő betű kijelölésnek felel meg, azaz az ’A’ időrést a 0 képviseli, a ’B’-t az 1, a ’C’-t a 2 … és a ’H’-t a 7. Az azonosítónál a Legkisebb Helyértékű Bit-et kell először leadni.

3.6.3.3.2 *Továbbítási hossz.* A továbbítási hossznak jeleznie kell mind az alkalmazási adat, mind az alkalmazási vevő oldali hibajavítás /FEC/ bitjeinek teljes számát. A továbbítási hossznál a Legkisebb Helyértékű Bit kerül először továbbításra.

3.6.3.3.3 *Impulzussorozat vevő oldali hibajavítás /FEC/.* Az impulzussorozat vevő oldali hibajavítást az Állomás időrés azonosítóval /SSID/ és a továbbítási hossz mezőkkel kell kiszámolni egy (25, 20) blokk kód felhasználásával, a következő egyenletnek megfelelően:

$$[\, P_1, \ldots, P_5 \,] = [\, SSID_1 , \ldots, SSID_3 , TL_1 ,\ldots, TL_{17} \,]\, H^T$$

ahol:

P_n	=	Az impulzussorozat vevő oldali hibajavítás /FEC/ n-dik bitje (a P_1 –et kell először továbbítani);
$SSID_n$	=	Az állomás időrés azonosító n-dik bitje ($SSID_1$ = Legkisebb Helyértékű Bit /LSB/);
TL_n	=	A továbbítási hossz n-dik bitje (TL_1 = Legkisebb Helyértékű Bit);
H^T	=	A paritás mátrix transzformációja, az alábbiak szerint meghatározva:

$$H^T = \begin{bmatrix} 0&0&0&0&0&0&0&0&1&1&1&1&1&1&1&1&1&1&1&1 \\ 0&0&1&1&1&1&1&1&0&0&0&0&1&1&1&1&1&1&1&1 \\ 1&1&0&0&0&1&1&1&0&0&1&1&0&0&0&0&1&1&1&1 \\ 1&1&0&1&1&0&1&1&0&1&0&1&0&0&1&1&0&0&1&1 \\ 0&1&1&0&1&0&0&1&1&1&1&0&0&1&0&1&0&1&0&1 \end{bmatrix}^T$$

Megjegyzés. – Ez a kód alkalmas arra, hogy az összes egyedüli bit hibákat kijavítsa, és arra is, hogy 300 lehetséges kettős bit hibából 75-öt észleljen.

3.6.3.3.4 *Alkalmazási adat.* Az alkalmazási adatnak egy, vagy több közlemény blokkból kell állnia, ahogy az a 3.6.3.4 pontban meghatározásra került. A közlemény blokkok közvetlenül lesznek az alkalmazási adatban leképezve, nincsenek kiegészítő beavatkozási rétegek.

3.6.3.3.5 *Alkalmazási vevő oldali hibajavítás /FEC/.* Az alkalmazási vevő oldali hibajavítást az alkalmazási adatokra egy szisztematikus, fix-hosszúságú, Reed-Solomon (R-S) (255, 249) kód segítségével kell kiszámolni.

3.6.3.3.5.1 Az R-S kód mező-meghatározó primitív egyenlete, a p(x), a következő lesz:

$$p(x) = x^8 + x^7 + x^2 + x + 1$$

3.6.3.3.5.2 Az R-S kód generáló polinomjának, a g(x)-nek, a következőnek kell lenni:

$$g(x) = \prod_{i=120}^{125} (x - \alpha^i) = x^6 + \alpha^{176}x^5 + \alpha^{186}x^4 + \alpha^{244}x^3 + \alpha^{176}x^2 + \alpha^{156}x + \alpha^{225}$$

ahol az α annak a p(x)-nek a gyöke, ami a 2^8 fokú Galois Mező, GF(256) összeállításához használatos és az α^i a GF(256) i-dik primitív eleme.

3.6.3.3.5.3 Az alkalmazási vevő oldali hibajavítás összeállításánál a kódolandó adatokat, m(x), 8-bites R-S szimbólumokká kell csoportosítani. A közlemény blokkokban az összes adatmezőt, amelyek az alkalmazási adatokat meghatározzák, úgy kell elrendezni, ahogy az a B-61. és B-62. táblázatokban és a 3.6.6 pont alatti közlemény-táblázatokban előírásra került. Azonban, mivel az R-S kód egy blokk-kód, a 249 byte-nál (1 992 bit) rövidebb alkalmazási adat-blokkokat ki kell bővíteni 249 byte-ra, nullára állított virtuális töltő bitekkel, és hozzá kell toldani az alkalmazási adatokhoz. Ezek a virtuális töltő bitek nem kerülnek továbbításra a bit keverőbe. A kódolandó adatokat, m(x), a következők szerint kell meghatározni:

$$m(x) = a_{248}x^{248} + a_{247}x^{247} + \dots + a_{248\text{-length}+1}\, x^{248\text{-length}+1} + a_{248\text{-length}}\, x^{248\text{-length}} + \dots + a_1x + a_0$$

ahol:

a ’hossz’ képviseli az alkalmazási adatokban lévő 8-bites byte-ok számát;

az a_{248} képviseli a közlemény blokk azonosítóját, a jobbról a legszélső bit van a Legkisebb Helyértékű Bitként /LSB/ meghatározva, és az alkalmazási adat első bitje kerül a bit keverőbe továbbításra;

az $a_{248\text{-hossz}+1}$ jelenti a közlemény blokk Ciklikus Redundancia Ellenőrzésének /CRC/ legutolsó byte-ját, a balról a legszélső bit van a Legnagyobb Helyértékű Bitként /MSB/ meghatározva, és az alkalmazási adat utolsó bitje kerül a bit keverőbe továbbításra;

az $a_{248\text{-hossz}}, \dots, a_1, a_0$ a virtuális kitöltő bitek (ha ilyen van).

3.6.3.3.5.4 A hat R-S ellenőrző szimbólumot (b_i) úgy kell meghatározni, hogy az a közlemény polinomnak, $x^6m(x)$, a generáló polinommal, g(x),való osztásából eredő maradék tényező:

$$b(x) = \sum_{i=0}^{5} b_ix^i + b_5x^5 + b_4x^4 + b_3x^3 + b_2x^2 + b_1x + b_0 = [x^6m(x)] \bmod g(x)$$

3.6.3.3.5.5 A 8-bites R-S ellenőrző szimbólumot csatolni kell az alkalmazási adathoz. Minden egyes 8-bites R-S ellenőrző szimbólumnál a Legnagyobb Helyértékű Bitet először leadva kell továbbítani a b_0-tól a b_5-ig, azaz az első alkalmazási vevő oldali hibajavító bitnek, ami a bit keverőbe továbbításra kerül, a b_0 Legnagyobb Helyértékű Bitnek és az utolsó alkalmazási vevő oldali hibajavító bitnek, ami a bit keverőbe kerül továbbításra, a b_5 Legkisebb Helyértékű Bitnek kell lenni.

1. Megjegyzés. – Ez az R-S kód képes arra, hogy maximum 3 szimbólum hibát kijavítson.

2. Megjegyzés. – A továbbított 8-bites R-S ellenőrző szimbólumok sorrendje a csatolt alkalmazási vevő oldali hibajavításnál eltér a VHF adattovábbítás (VDL) 2. Módjától. Azonkívül a VDL 2. Módnál az egyes R-S ellenőrző szimbólumokat a Legkisebb Helyértékű Bitet először leadva kell továbbítani.

3. Megjegyzés. – Az alkalmazási vevő oldali hibajavítás /FEC/ kódolási eredményeinek példái a "D"-Melléklet 7.15 pontjában kerültek megadásra.

B-61. táblázat: A Földi Bázisú Kiegészítő Rendszer /GBAS/ közlemény blokkjának formátuma

Közlemény blokk	Bitek
Közlemény blokk fejrész	48
Közlemény	1 696-ig
Ciklikus Redundancia Ellenőrzés	32

B-62. táblázat: A közlemény blokk fejrészének formátuma

Adatmező	Bitek
Közlemény blokk azonosító	8
GBAS azonosító /ID/	24
Közlemény típus azonosító	8
Közlemény hossz	8

3.6.3.3.6 *Bit keverés*

3.6.3.3.6.1 Az ál-véletlen zaj keverő kimenetén egy 15-fokozatú generátor regiszterrel kell 'kizáró VAGY'-olni a szinkron vezér jel adatokat, az Állomás Időrés Azonosítóval /SSID/ kezdve és a vevő oldali hibajavítással /FEC/ befejezve. A kitöltő bitek bit keverése választható, és a kitöltő bitek beállítási értéke is választható.

Megjegyzés. – A kitöltő biteket a légijármű fedélzeti vevő nem használja fel, és azok értékének nincs hatása a rendszerre.

3.6.3.3.6.2 A keverő regiszter csapjainak polinomja $1 + x + x^{15}$ kell, hogy legyen. A regiszter tartalmát bitenként egy léptetés sebességgel kell váltani. A regiszter beinduló állapota, az egyes szinkron vezér jelek első Állomás Időrés Azonosítóját /SSID/ megelőzően „1101 0010 1011 001" kell, hogy legyen, balról, a legelső bittel a regiszter első fokozatában. A keverő első kimeneti bitjét az első regiszter léptetés előtt mintavételezni kell.

Megjegyzés. – A bit keverő ábrája a "D"- Melléklet 7.4 pontjában került megadásra.

3.6.3.4 *Közlemény blokk formátum*. A közlemény blokknak egy közlemény blokk fejrészből, a közleményből és egy 32 bites Ciklikus Redundancia Ellenőrzésből /CRC/ kell állni.

A B-61. táblázat mutatja be a közlemény blokk szerkezetét. Az összes előjeles paraméternek kettős kiegészítő számnak kell lenni, és az összes előjel nélküli paraméternek előjel nélküli fix-pontos számnak kell lenni. Az adatok leosztásának a 3.6.6 pont közlemény táblázataiban bemutatottaknak kell lenni. A közlemény blokkban lévő összes adatmezőt a közlemény táblázatokban meghatározott sorrendben kell továbbítani, az egyes mezők Legkisebb Helyértékű Bitjét /LSB/ először továbbítva.

Megjegyzés. - Az összes bináris adat felírás kiolvasása balról jobbra a Legnagyobb Helyértékű Bittől /MSB/ a Legkisebb Helyértékű Bitig /LSB/ történik.

3.6.3.4.1 *Közlemény blokk fejrész*. A közlemény blokk fejrésznek egy közlemény blokk azonosítót, egy Földi Bázisú Kiegészítő Rendszer /GBAS/ azonosítót /ID/, egy közlemény típus azonosítót és egy közlemény hosszt kell magába foglalnia, ahogy az a B-62. táblázatban bemutatásra került.

Közlemény blokk azonosító: a GBAS közlemény blokk üzemelési módjának 8-bites azonosítója.

Kódolás: 1010 1010 = szabvány GBAS közlemény
1111 1111 = vizsgálati GBAS közlemény
Az összes további érték fenntartva.

GBAS azonosító /ID/: a sugárzó állomások közötti különbségtételhez a négy-karakteres GBAS azonosító.

Kódolás: Az egyes karakterek kódolása a biteket b_1-től b_6-ig terjedően felhasználva az 5.sz. Nemzetközi ABC (IA-5) felírással történik. Az egyes karaktereknél a b_1 bit kerül először továbbításra és a hat bit minden egyes karaktere leadásra kerül. Csak a nagybetűk, a számjegyek és az IA-5 „szóköz” használatos. A jobbról a legszélső karakter kerül először leadásra. Egy három-karakteres GBAS azonosítóhoz /ID/ a jobbról legszélső (az először továbbított) karakternek az IA-5 „szóközének” kell lenni.

Megjegyzés. – A GBAS azonosító /ID/ általában megegyezik a legközelebbi repülőtér helységnév azonosítójával. A GBAS ID kijelölése egyeztetésre fog kerülni - ahogy az megfelelő - az ütköztetések elkerülése céljából.

Közlemény típus azonosító: egy szám-szerű ’címke’, ami a közlemény tartalmát azonosítja (B-63. táblázat).

Közlemény hossz: a közlemény hossza 8-bites byte-okban, beleértve a 6 byte-os közlemény blokk fejrészt, a közleményt és a 4 byte-os közlemény Ciklikus Redundancia Ellenőrző kódot.

3.6.3.4.2 *Ciklikus Redundancia Ellenőrzés (CRC)*. A GBAS közlemény CRC-t a 3.9 pontban megadottaknak megfelelően kell kiszámolni.

3.6.3.4.2.1 A CRC-kód hosszának k = 32 bitnek kell lenni.

3.6.3.4.2.2 A CRC generáló polinomjának a következőnek kell lenni:

$$G(x) = x^{32} + x^{31} + x^{24} + x^{22} + x^{16} + x^{14} + x^{8} + x^{7} + x^{5} + x^{3} + x + 1$$

3.6.3.4.2.3 A CRC információs mezőjének, M(x), a következőnek kell lenni:

$$M(x) = \sum_{i=1}^{n} m_i x^{n-i} = m_1 x^{n-1} + m_2 x^{n-2} + \ldots + m_n x^0$$

3.6.3.4.2.4 Az M(x)-et a 48-bites GBAS közlemény blokk fejrészből és a különböző hosszúságú közlemény összes bitjéből kell kialakítani, a CRC-t is beleértve. A biteket a továbbítási sorrendben kell elrendezni úgy, hogy az m_n feleljen meg a közlemény bitek (n-48) legutolsó továbbított bitjének.

3.6.3.4.2.5 A CRC-t úgy kell elrendezni, hogy az r_1 legyen a legelső továbbított bit és az r_{32} a legutolsó továbbított bit.

3.6.4 ADAT TARTALOM

3.6.4.1 *Közlemény típusok.* Azoknak a közlemény típusoknak, amelyeket a Földi Bázisú Kiegészítő Rendszerrel /GBAS/ továbbítani lehet, a B-63. táblázatban felsoroltaknak kell lenni.

Megjegyzés. – Jelenleg a 256 rendelkezésre álló közlemény típusból csak 8 került meghatározásra, azzal a szándékkal, hogy a jövő szükségleteit a fennmaradó közlemény típusoknak lehet címezni.

3.6.4.2 *1. Típusú közlemény – Pszeudo-távolság helyesbítések*

3.6.4.2.1 Az 1.Típusú közleménynek kell biztosítani a differenciál helyesbítési adatokat az egyedi Globális Navigációs Műhold Rendszer /GNSS/ távolság-meghatározási forrásai részére (B-70. táblázat). A közleménynek 3 részt kell magába foglalni:

a) közlemény tájékoztatás (az érvényesség ideje, kiegészítő közlemény jelző, a mérések száma és a mérések típusa);

b) alacsony-frekvenciás információk (efemerisz dekollerációs tényező, műhold efemerisz Ciklikus Redundancia Ellenőrzés /CRC/ és műhold rendelkezésre állási információ); és

c) műhold adat mérési blokkok.

Megjegyzés. – A Műhold Bázisú Kiegészítő Rendszer /SBAS/ távolság-meghatározási források alacsony-frekvenciás adatainak továbbítása választható.

3.6.4.2.2 Az egyes 1. Típusú közleményeknek magukba kell foglalniuk az efemerisz dekollerációs tényezőt, az efemerisz CRC-t és a forrás rendelkezésre állási időtartam paramétereket egy műhold távolság-meghatározási forrására. Az efemerisz dekorrelációs tényezőt, az efemerisz CRC-t és a forrás rendelkezésre állási időtartamot a közleményben lévő első távolság-meghatározási forrásra kell alkalmazni.

3.6.4.2.3 A pszeudo-távolság helyesbítési paramétereknek a következőknek kell lenni:

Módosított Z-számítás: a közleményben lévő összes paraméter alkalmazhatósági idejének a jelzése.

Kódolás: a módosított Z-számítás újraállítja az időt, az órakor (xx:00), 20 perccel az óra után (xx:20) és 40 perccel az óra után (xx:40) a Globális Helymeghatározó Rendszer /GPS/ idejéhez vonatkoztatottan.

Kiegészítő közlemény jelző: annak a jelzése, hogy a mérési blokkok sorozatát egy egyedüli keretben egy meghatározott egyedi mérés típusra vonatkozóan, vagy egy egyedüli, 1. Típusú közlemény foglalja-e magába, vagy egy összekapcsolt közlemény pár.

Kódolás:	0	=	Egy meghatározott mérés típus összes mérési blokkját egy 1. Típusú közlemény foglalja magába.
	1	=	Az olyan 1. Típusú közlemények összekapcsolt párjának első továbbított közleménye, amelyek együtt foglalják magukba egy meghatározott mérés típus összes mérési blokkjának sorozatát.
	2	=	Tartalék.
	3	=	Az olyan 1. Típusú közlemények összekapcsolt párjának második továbbított közleménye, amelyek együtt foglalják magukba egy meghatározott mérés típus összes mérési blokkjának sorozatát.

Megjegyzés. – Amikor az 1. Típusú közlemények egy összekapcsolt párja használatos egy meghatározott mérési típusra, akkor a mérések száma, az efemerisz CRC és a forrás rendelkezésre állási paraméterek külön-külön kerülnek kiszámításra a két egyedi közlemény mindegyikére.

Mérések száma: a mérési blokkok száma a közleményben.

Mérések típusa: annak a távolság-meghatározási jelnek a típusa, amelyből a helyesbítések kiszámításra kerültek.

B-63. táblázat: A Földi Bázisú Kiegészítő Rendszer /GBAS/ VHF adat sugárzási közlemények

Közlemény típus azonosító	Közlemény név
0	Tartalék
1	Pszeudo-távolság helyesbítés
2	GBAS vonatkozású adatok
3	Fenntartva a földi-bázisú távolság-meghatározási forrás részére
4	Végső Megközelítési Szakasz /FAS/ adatok
5	Előrejelzett távolság-meghatározási forrás rendelkezésre állás
6	Fenntartott
7	Fenntartva nemzeti alkalmazásokra
8	Fenntartva ellenőrző alkalmazásokra
9 –255	Tartalék

Megjegyzés. – Lásd a 3.6.6 pontban a közlemény formátumokat.

Kódolás:	0	=	C/A, vagy CSA kód L1
	1	=	Fenntartva
	2	=	Fenntartva
	3	=	Fenntartva
	4-től 7-ig	=	Tartalék

Efemerisz dekorrelációs tényező (P): Az a tényező, amely a dekolleráció miatti megmaradó efemerisz hibákat írja le a közlemény első mérési blokkjára.

A Műhold Bázisú Kiegészítő Rendszer /SBAS/ geostacionárius műholdjaira a dekollerációs tényezőt, ha sugárzásra kerül, a kódsorban minden helyen 0-ként kell kódolni.

A Földi Bázisú Kiegészítő Rendszer /GBAS/ földi állomásaira azért, hogy a 2.típusú közleményben a kiegészítő 1. adatblokkot ne sugározzák, az efemerisz dekolláricós tényezőt a kódsorban minden helyen 0-ként kell kódolni.

Efemerisz CRC: Az efemerisz adatokkal számított Ciklikus Redundancia Ellenőrzés /CRC/ a közleményben lévő első mérési blokk helyesbítéseinek meghatározására használatos. A műholdak helyzetsor rendszere(i)vel távolság-meghatározási forrásokra vonatkozó efemerisz CRC-t a 3. pontban leírtaknak megfelelően kell kiszámítani. A CRC kód hosszának
k = 16 bit-nek kell lenni. A CRC generáló polinomja a következő:

$$G(x) = x^{16} + x^{12} + x^{5} + 1$$

A CRC információs mezője, az M(x), egy adott műholdra a következő:

$$M(x) = \sum_{i=1}^{n} m_i x^{n-i} = m_1 x^{n-1} + m_2 x^{n-2} + \ldots + m_n x^0$$

Egy Globális Helymeghatározási Rendszerű /GPS/ műholdra az M(x)-nek n = 576 bit hosszúságúnak kell lenni. Az M(x)-et egy GPS műholdra úgy kell kiszámítani, hogy az adott műhold adattovábbítás 1., 2. és 3. al-keretének a 3.-tól az S10.-ig terjedő szavai első 24 bitjét használják fel, ÉS-elve alkalmazásával /ANDed/ a B-64. táblázat GPS műhold efemerisz maszkjával. Az M(x)-et olyan sorrendben kell elrendezni, ahogy a byte-okat a GPS műhold továbbítja, de úgy, hogy az egyes byte-oknál a Legkisebb Helyértékű Bitet kell elsőnek rendelni, azaz úgy, hogy az m_1 feleljen meg az 1. al-keret 68. bitjének és az m_{576} feleljen meg a 3. al-keret 287. bitjének.

Megjegyzés. – A GPS műhold M(x)-e nem foglalja magába az 1. szót (TLM = Távolságmérés) és a 2. szót (HOW = Átadás), amelyekkel minden al-keret kezdődik, vagy az egyes szavak végén lévő 6 paritás bitet.

A GLONASS műholdra az M(x)-nek n = 340 bit hosszúságúnak kell lenni. Az M(x)-et egy GLONASS műholdra az annak a műholdnak az adattovábbítási 1., 2. 3. és 4. jelsorozatának felhasználásával kell kiszámítani, ÉS-elve alkalmazásával /ANDed/ a B-65. táblázatban lévő GLONASS műhold efemerisz maszkkal. A biteket a továbbítási sorrendben úgy kell elrendezni, hogy az m_1 feleljen meg az 1.jelsorozat 85. bitjének és az m_{340} feleljen meg a 4. jelsorozat 1. bitjének.

Egy Műhold Bázisú Kiegészítő Rendszer /SBAS/ geostacionárius műholdnak, az efemerisz CRC-t - ha továbbításra kerül - a kódsorban minden helyen nullaként kell kódolni. A CRC-t úgy kell elrendezni, hogy az r_1 legyen az elsőként továbbított bit és az r_{16} az utolsóként továbbított bit.

Forrás rendelkezésre állási időtartam: az az előre jelzett időtartam, amelyre a távolság-meghatározási forrásra vonatkozó helyesbítések várhatóan rendelkezésre állók maradnak az első mérési blokk módosított Z-számlálásához vonatkoztatva.

Kódolás: 1111 1110 = Az időtartam nagyobb, vagy egyenlő 2 540 másodperccel.
1111 1111 = Forrás rendelkezésre állási időtartam előrejelzést ez a földi al-rendszer nem biztosít.

3.6.4.2.4 A mérési blokk paraméterei a következők kell, hogy legyenek:

Távolság-meghatározási forrás azonosító /ID/: annak a távolság-meghatározási forrásnak az azonosítója, amelyre a következő mérési blokk adatok alkalmazhatók.

B-64. táblázat: GPS műhold efemerisz maszk

B-65. táblázat: GLONASS műhold efemerisz maszk

1. Jelsorozat: 0 0000 0000 0000 0000 0000 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 111 1111 1111 0000 0000 2. Jelsorozat: 0 0000 0000 0000 0000 0000 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 111 1111 1111 0000 0000 3. Jelsorozat: 0 0000 0111 1111 1111 0000 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 1111 0000 0000 4. Jelsorozat: 0 0000 1111 1111 1111 1111 1111 1100 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000

Kódolás: 1.-től 36.-ig = GPS műhold azonosítók /ID/ (Ál-véletlen zaj /PRN/)
37. = Fenntartott
38.-tól 61.-ig = GLONASS műhold azonosító (időrés szám + 37)
62.-től 119.-ig = Tartalék
120.-tól 138.-ig = SBAS műhold azonosítók /ID/ (Ál-véletlen zaj /PRN/) 139.-től 255.-ig = Tartalék

Adatkibocsátás (IOD): Az efemerisz adatokhoz kapcsolódó adatkibocsátás a pszeudo-távolság és a távolság-meghatározási változás helyesbítések meghatározásához használatosak.

Kódolás: GPS, IOD-re = GPS Adatkibocsátás, Efemerisz /IODE/ paraméter (3.1.1.3.2.2)
GLONASS IOD-re = GLONASS „t_b” paraméter (lásd 3.2.1.3.1)
SBAS, IOD-re = 1111 1111

Megjegyzés. – A GLONASS-ra az IOD Legnagyobb Helyértékű Bitjébe (MSB) 0-t építsenek be.

Pszeudo-távolság helyesbítés (PRC): a távolság-meghatározási forrás pszeudo-távolságának helyesbítése.

Távolság-meghatározási változás helyesbítés (RRC): a pszeudo-távolság helyesbítés változási gyakorisága.

σ_{pr_gnd} : a pszeudo-távolság hibához hozzájáruló, a térbeli-jelhez kapcsolódó szabályos eloszlás szabvány eltérése a referencia pontban (3.6.5.5.1, 3.6.5.5.2 és 3.6.7.2.2.4).

Kódolás: 1111 1111 = A távolság-meghatározási forrás helyesbítés érvénytelen.

B_1 –től a B_4-ig: a pszeudo-távolság helyesbítésekhez kapcsolódó azon sértetlenségi paraméterek, amelyek ugyanazon mérési blokkban kerülnek biztosításra. Az i-dik távolság-meghatározási forrásra ezek a paraméterek megegyeznek a $B_{i,1}$ –től a $B_{i,4}$-ig terjedőkkel (3.6.5.5.1.2, 3.6.5.5.2.2 és 3.6.7.2.2.4).

Kódolás: 1000 0000 = A pszeudo-távolság helyesbítések kiszámításához referencia vevő nem került felhasználásra.

3.6.4.3 *2. Típusú közlemény – Földi Bázisú Kiegészítő Rendszer /GBAS/ vonatkozású adatok.* A 2. Típusú közleményeknek annak a GBAS referencia pontnak a helyét kell azonosítani, amelyről a felhasznált GBAS-helyesbítéseket biztosítja és további egyéb GBAS vonatkozású adatokat kell adni. (B-71. táblázat). A GBAS vonatkozású adatok paramétereinek a következőknek kell lenni:

Megjegyzés. – Kiegészítő adatblokkot lehet a 2. típusú közleménybe befoglalni.
Az 1. kiegészítő adatblokk és a 2. kiegészítő adatblokk meghatározásra került. A jövőben további kiegészítő adatblokkokat lehet meghatározni. A 2.-tól a 255.-ik tartó kiegészítő adatblokkok változó hosszúságúak és a közleményhez csatolhatók az 1. adatblokk után bármilyen sorrendben.
GBAS referencia vevők: azoknak a Globális Navigációs Műhold Rendszer /GNSS/ vevőknek a száma, amelyek ebben a GBAS-ben üzembeállításra kerültek.

Kódolás: 0 = 2 referencia vevővel felszerelt GBAS
1 = 3 referencia vevővel felszerelt GBAS
2 = 4 referencia vevővel felszerelt GBAS
3 = Az ebben a GBAS földi al-rendszerbe telepített GNSS referencia vevők száma nem alkalmazható

Földi pontosság jelölő betű: a betű jelölés a GBAS által biztosított minimális térbeli-jel pontossági teljesítményt jelzi (3.6.7.1.1).

Kódolás: 0 = 'A' pontossági jelölés
1 = 'B' pontossági jelölés
2 = 'C' pontossági jelölés
3 = Tartalék

GBAS folytonossági/sértetlenségi jelölés (GCID): a GBAS működési állapotát jelző számszerű jelölés.

Kódolás: 0 = Tartalék
1 = GCID 1
2 = GCID 2
3 = GCID 3
4 = GCID 4
5 = Tartalék
6 = Tartalék
7 = Hibás működési állapot /'egészségtelen'/

1. Megjegyzés. – A GCID 2., 3. és 4. értékei abból a célból kerültek meghatározásra, hogy biztosítsák a jövő GBAS rendszereinek az I. kategóriájú berendezésekkel való kompatibilitását.

2. Megjegyzés. – A GCID 7. értéke azt jelzi, hogy egy precíziós megközelítést, vagy APV-t nem lehet megkezdeni.

Helyi mágneses elhajlás: a GBAS referencia pontjára közzétett mágneses elhajlás.

Kódolás: A pozitív érték a keleti elhajlást (a földrajzi északtól az óramutató járásával megegyező irányú), a negatív érték a nyugati elhajlást (a földrajzi északtól az óramutató járásával ellentétes irányú) jelzi.
100 0000 0000 = az ezen GBAS által alátámasztott közzétett precíziós megközelítési eljárások a földrajzi északon alapulnak.

Megjegyzés. – A helyi mágneses elhajlásnak meg kell egyezni az eljárás tervezésére meghatározott értékkel, és azok a mágneses eltérés 'korszak' éveinek megfelelően felfrissített értékek.

$\sigma_{vert\_iono\_gradient}$: a térbeli dekorreláció (3.6.5.4) miatti megmaradó ionoszférikus bizonytalansághoz kapcsolódó szabályos eloszlás szabvány eltérése.
Törési index (N_r): névleges troposzférikus törési index, ami a GBAS földi állomáshoz kapcsolódó troposzférikus helyesbítés kalibrálásához használatos (3.6.5.3).

Kódolás: Ez a mező mint kettős számú összetevőként egy +400-as eltolással kerül kódolásra. Ebben a mezőben a 0 érték egy 400-as törési indexet jelez.

Skála magasság (h_0): lépték tényező, amely a GBAS földi al-rendszerhez kapcsolódó troposzférikus helyesbítés és a megmaradó troposzférikus bizonytalanság kalibrálásához használatos (3.6.5.3).

Törési bizonytalanság (σ_n): a megmaradó troposzférikus bizonytalansághoz kapcsolódó szabályos eloszlás szabvány eltérése (3.6.5.3).

Földrajzi szélesség: a GBAS referencia pont földrajzi szélessége ív-másodpercben meghatározva.

Kódolás: A pozitív érték az északi szélességet fejezi ki.
A negatív érték a déli szélességet fejezi ki.

Földrajzi hosszúság: a GBAS referencia pont földrajzi hosszúsága ív-másodpercben meghatározva.

Kódolás: A pozitív érték a keleti hosszúságot fejezi ki.
A negatív érték a nyugati hosszúságot fejezi ki.

Referencia pont magasság: a GBAS referencia pontnak a WGS-84 ellipszoid feletti magassága.

3.6.4.3.1 *Az 1. kiegészítő adatblokk paraméterei.* Az 1. kiegészítő adatblokk paraméterei a következők:

REFERENCIA ÁLLOMÁS ADAT KIVÁLASZTÓ (RSDS): Az az azonosító szám, amely a GBAS helymeghatározási szolgáltatást biztosító állomás kiválasztására használatos.

Megjegyzés. – Az RSDS különbözik az összes többi RSDS-től és az összes Referencia Pálya Adat Kiválasztótól /RPDS/, ami az összes, a sugárzási területen belül lévő GBAS földi al-rendszer által ugyanazon a frekvencián továbbításra kerül.

Kódolás: 1111 1111 = A GBAS helymeghatározási szolgáltatás nincs biztosítva.

MAXIMÁLIS FELHASZNÁLÁSI TÁVOLSÁG (D_{max}): A GBAS referencia ponttól az a maximális távolság (ferdetávolság), amelyre a teljesség /integritás/ biztosítva van.

Megjegyzés. – Ez a paraméter nem azt a távolságot jelzi, amelyen belül a VHF adatsugárzási térerősség követelmények kielégítésre kerülnek.

Kódolás: 0 = Nincs távolság korlátozás.

GPS EFEMERISZ HIBÁS ÉSZLELÉSI EGYÜTTHATÓ, GBAS Hely-meghatározási Szolgáltatás ($K_{md\_e\_POS, GPS}$): A hibás észlelés valószínűségéből származó, a GBAS Helymeghatározási Szolgáltatáshoz kapcsolódó efemerisz hibás helyzet határ kiszámításának szorzója, feltéve, hogy egy efemerisz hiba áll fenn a GPS műholdban.

Az olyan GBAS földi al-rendszereknél, amelyek nem sugároznak helyesbítéseket a GPS távolságmérési forrásokra, vagy amelyek nem biztosítanak GBAS helymeghatározási szolgáltatásokat, ezt a paramétert a kódsorban minden helyen 0-ként kell kódolni.

GPS EFEMERISZ HIBÁS ÉSZLELÉSI EGYÜTTHATÓ I. kategóriájú precíziós megközelítés és APV ($K_{md\_e,, GPS}$): A hibás észlelés valószínűségéből származó, az I.kategóriájú precíziós megközelítéshez és APV-hez kapcsolódó efemerisz hibás helyzet határ kiszámításának szorzója, feltéve, hogy egy efemerisz hiba áll fenn a GPS műholdban.

Az olyan GBAS földi al-rendszereknél, amelyek nem sugároznak helyesbítéseket a GPS távolságmérési forrásokra, ezt a paramétert a kódsorban minden helyen 0-ként kell kódolni.

GLONASS EFEMERISZ HIBÁS ÉSZLELÉSI EGYÜTTHATÓ, GBAS Hely-meghatározási Szolgáltatás ($K_{md\_e\_POS,GLONASS}$): A hibás észlelés valószínűségéből származó, a GBAS Helymeghatározási Szolgáltatáshoz kapcsolódó efemerisz hibás helyzet határ kiszámításának szorzója, feltéve, hogy egy efemerisz hiba áll fenn a GLONASS műholdban.

Az olyan GBAS földi al-rendszereknél, amelyek nem sugároznak helyesbítéseket a GLONASS távolságmérési forrásokra vagy amelyek nem biztosítanak GBAS helymeghatározási szolgáltatásokat, ezt a paramétert a kódsorban minden helyen 0-ként kell kódolni.

GLONASS EFEMERISZ HIBÁS ÉSZLELÉSI EGYÜTTHATÓ I. kategóriájú precíziós megközelítés és APV ($K_{md\_e, GLONASS}$): A hibás észlelés valószínűségéből származó, az I.kategóriájú precíziós megközelítéshez és az APV-hez kapcsolódó efemerisz hibás helyzet határ kiszámításának szorzója, feltéve, hogy egy efemerisz hiba áll fenn a GLONASS műholdban.

Az olyan GBAS földi al-rendszereknél, amelyek nem sugároznak helyesbítéseket a GLONASS távolságmérési forrásokra, ezt a paramétert a kódsorban minden helyen 0-ként kell kódolni.

3.6.4.3.2 *Kiegészítő adat blokkok.* Az 1. kiegészítő adat blokktól eltérő kiegészítő adat blokkoknál a paramétereknek a következőknek kell lenni:

KIEGÉSZÍTŐ ADAT BLOKK SZÁM: A kiegészítő adat blokk típusának számszerű azonosítója.

Kódolás: 0-tól 1-ig = fenntartva
2 = 2. kiegészítő adat blokk, GRAS továbbító állomások
3-tól 255-ig = tartalék

KIEGÉSZÍTŐ ADAT PARAMÉTEREK: a kiegészítő adat blokk számnak megfelelően meghatározott adat készlet.

3.6.4.3.2.1 *GRAS továbbító állomások*

A 2. kiegészítő adat blokk paramétereinek a következő adatot kell tartalmazni egy, vagy több továbbító állomás számára:

CSATORNA SZÁM: Egy GBAS továbbító állomáshoz kiosztott csatorna szám, a 3.6.5.7 pontban megadottaknak megfelelően.

Megjegyzés. – Az ebben a területben lévő csatorna szám egy frekvenciára és egy Referencia Állomás Adat Kiválasztó-ra (RSDS) utal.

Δ*Földrajzi szélesség*: egy GBAS továbbító állomás földrajzi szélesség eltérése, a 2. típusú közlemény földrajzi szélesség paraméterében rögzített földrajzi szélességétől mérve.

Kódolás: A pozitív érték azt fejezi ki, hogy a GBAS továbbító állomás a GBAS referencia ponttól északra van.

A negatív érték azt fejezi ki, hogy a GBAS továbbító állomás a GBAS referencia ponttól délre van.

Δ*Földrajzi hosszúság*: egy GBAS továbbító állomás földrajzi hosszúság eltérése, a 2. típusú közlemény földrajzi hosszúság paraméterében rögzített földrajzi hosszúságától mérve.

Kódolás: A pozitív érték azt fejezi ki, hogy a GBAS továbbító állomás a GBAS referencia ponttól keletre van.
A negatív érték azt fejezi ki, hogy a GBAS továbbító állomás a GBAS referencia ponttól nyugatra van.

Megjegyzés. – A 2. kiegészítő adat blokkal kapcsolatos útmutató anyag a "D"- Melléklet 7.17 pontjában található.

3.6.4.4 *3. Típusú közlemény*

Megjegyzés. – A 3. Típusú közlemények tervezett felhasználása a földi bázisú távolság-meghatározási forrásokhoz szükséges információk biztosítása és a jövőbeli alkalmazásra kerültek fenntartásra.

3.6.4.5 *4. Típusú közlemény – Végső megközelítési szakasz (FAS)*. A 4. Típusú közleménynek egy, vagy több Végső Megközelítési Szakasz adatállományát kell magába foglalni, amelyek mindegyike egy önálló precíziós megközelítést határoz meg (B-72. táblázat). Minden egyes 4. Típusú közlemény adatállományának a következőket kell magába foglalni:

Adatállomány hossz: Az adatállományban lévő byte-ok száma. Az adatállomány magába foglalja az adatállomány hossz mezőt és a hozzá kapcsolódó Végső Megközelítési Szakasz /FAS/ adat blokkot, a FAS függőleges riasztási határértéket (FASVAL)/megközelítési állapot és FAS oldalirányú riasztási határérték (FASLAL)/megközelítési állapot mezőket.

Végső megközelítési szakasz /FAS/ adat blokk: egy paraméter sorozat egy önálló precíziós megközelítés azonosításához és a kapcsolódó megközelítési pálya meghatározásához.

Kódolás: Lásd a 3.6.4.5.1 pontot és a B-66. táblázatot.
Megjegyzés. – A FAS pálya meghatározására vonatkozó útmutató anyagot a „D"- Melléklet 7.11.1 pontja foglalja magába.

Végső megközelítési szakasz Függőleges riasztási határérték /FASVAL/ /megközelítési állapot: A FASVAL paraméter értéke, ahogy az a 3.6.5.6 pont szerint alkalmazásra kerül.

Kódolás: 1111 1111 = Ne használjon függőleges eltéréseket.

Megjegyzés. – A Végső megközelítési szakasz Függőleges riasztási határérték /FASVAL/ tartománya és felbontása a kapcsolódó Végső Megközelítési Szakasz (FAS) adat blokkban lévő megközelítési működés azonosítótól függ.

Végső megközelítési szakasz Oldalirányú riasztási határérték /FASLAL/ /megközelítési állapot: A FASLAL paraméter értéke, ahogy az a 3.6.5.6 pont szerint alkalmazásra kerül.

Kódolás: 1111 1111 = Ne használja a megközelítést.

B-65A. táblázat: GRAS továbbító állomás adat

Adat tartalom	Felhasznált bitek száma	Értéktartomány	Felbontás
Csatorna szám	16	20001-től 39999-ig	1
ΔFöldrajzi szélesség	8	±25,4º	0,2º
ΔFöldrajzi hosszúság	8	±25,4º	0,2º

B-66. táblázat: Végső megközelítési szakasz (FAS) adat blokk

Adat tartalom	Felhasznált bit	Értéktartomány	Felbontás
Üzemeltetés típus	4	0-tól 15-ig	1
SBAS szolgáltatás biztosító azonosító /ID/	4	0-tól 15-ig	1
Repülőtér azonosító	32	—	—
Futópálya azonosító szám	6	0-tól 36-ig	1
Futópálya azonosító betű	2	—	—
Megközelítési teljesítmény jelölés	3	0-tól 7-ig	1
Útvonal jelzés	5	—	—
Referencia pálya adat kiválasztó	8	0-tól 48-ig	1
Referencia pálya azonosító	32	—	—
Leszállási küszöb-pont /LTP/ /Látszólagos küszöb-pont /FTP/ földrajzi szélesség	32	± 90°	0,0005 ív-másodperc
Leszállási küszöb-pont /LTP/ /Látszólagos küszöb-pont /FTP/ földrajzi hosszúság	32	± 180°	0,0005 ív-másodperc
Leszállási küszöb-pont /LTP/ /Látszólagos küszöb-pont /FTP/ magasság	16	-512,0-tól 6 041,5 m-ig	0,1 m
Repülési pálya irány-pont ΔFPAP földrajzi szélesség	24	± 1°	0,0005 ív-másodperc
Repülési pálya irány-pont ΔFPAP földrajzi hosszúság	24	± 1°	0,0005 ív-másodperc
Megközelítési küszöb keresztezési magasság /TCH/ (Megjegyzés)	15	0-tól 1 638,35 m-ig (0-tól 3 276,7 láb-ig)	0,05 m (0,1 láb)
Megközelítési küszöb keresztezési magasság /TCH/ mértékegység kiválasztó	1	—	—
Siklópálya szög /GPA/	16	0-tól 90,0°-ig	0,01°
Útirány szélesség	8	80-tól 143,75 m-ig	0,25 m
ΔHossz távolság /eltolás/	8	0-tól 2 032 m-ig	8 m
Végső megközelítési szakasz Ciklikus Redundancia Ellenőrzés /CRC/	32	—	—

1. Megjegyzés. – Amikor a futópálya azonosító szám 0-ra van állítva, akkor az útirány szélességmező elhagyásra kerül, és az útirány szélesség 38 méter.

2. Megjegyzés. – A tájékoztatást vagy láb-ban /feet/, vagy méter-ben lehet biztosítani, ahogy azt a megközelítési küszöb keresztezési magasság /TCH/ mértékegység kiválasztó jelzi.

3.6.4.5.1 *Végső megközelítési szakasz /FAS/ adat blokk*. A FAS adat blokknak magába kell foglalnia azokat a paramétereket, amelyek egy önálló precíziós megközelítést meghatároznak. A FAS pálya egy térbeli vonal, amelyet a Leszállási küszöb-pont/Látszólagos küszöb-pont (LTP/FTP), a Repülési pálya irány-pont (FPAP), a küszöb keresztezési magasság (TCH) és a Siklópálya szög (GPA) határoz meg. A helyi megközelítési szint síkja egy olyan sík, amely a helyi LTP/FTP-n áthaladó függőleges síkra merőleges (azaz az LTP/FTP-nél érintője az ellipszoidnak). A megközelítés helyi függőlegese az LTP/FTP-nél lévő WGS-84 ellipszoidra merőleges. A Siklópálya befogási pontja (GPIP) az a pont, ahol a végső megközelítési pálya vonala metszi a helyi szint síkját. A FAS adat blokk paraméterei a következők kell, hogy legyenek:

Üzemeltetés típus: közvetlen egyenes megközelítési eljárás, vagy más, egyéb típusú üzemeltetés.

Kódolás: 0 = közvetlen egyenes megközelítési eljárás
1-től 15-ig = tartalék

SBAS szolgáltatás biztosító azonosító /ID/: a FAS adat blokkhoz kapcsolódó szolgáltatás biztosítót jelzi.

Kódolás: Lásd a B-27. táblázatot.
14 = a FAS adat blokk csak a GBAS-el használható.
15 = a FAS adat blokkot bármelyik SBAS szolgáltatás biztosítóval együtt lehet használni.

Megjegyzés. – Ez a paraméter nem használatos a GBAS pszeudo-távolság helyesbítés felhasználásával végrehajtott megközelítésekre.

Repülőtér azonosító: a repülőtér jelölésére használatos három,- vagy négy-betűs azonosító jelzés.

Kódolás: Az egyes karakterek kódolása az 5.sz. Nemzetközi ABC (IA-5) felírása az alsó 6 bitjének felhasználásával történik. Az egyes karaktereknél a b_1 bit kerül először továbbításra és a b_6 után két kiegészítő nulla bit van, úgy, hogy a nyolc bit minden egyes karakterhez leadásra kerül. Csak a nagybetűk, a számjegyek és az IA-5 „szóköz" használatos. A jobbról a legszélső karakter kerül először leadásra. Egy három-karakteres GBAS azonosítóhoz /ID/ a jobbról legszélső (az először továbbított) karakternek az IA-5 „szóközének" kell lenni.

Futópálya azonosító szám: a megközelítési eljárás futópályájának azonosító száma.

Kódolás: 0 = helikopter-repülőtér
1-től 36-ig = futópálya azonosító szám

Futópálya azonosító betű: az egy-betűs jelölés használata akkor szükséges, amikor a párhuzamos futópályák között különbséget kell tenni.

Kódolás: 0 = nincs betű
1 = R (jobb)
2 = C (középső)
3 = L (bal)

Megközelítési teljesítmény jelölés: általános tájékoztatás a megközelítés tervezett pontossági típusáról.

Kódolás: 0 = APV (Megközelítés Függőleges Vezetéssel)
1 = I. kategória
2 = a II. kategóriára fenntartva
3 = a III. kategóriára fenntartva
4-től 7-ig = tartalék

Útvonal jelzés: egy egy-betűs azonosító, az ugyanazon futópálya-végre vezető több megközelítés közötti különbségtételre használatos.

Kódolás: A betű 5.sz. Nemzetközi ABC (IA-5) felírása a b_1 –től a b_6 –ig terjedő bitjeinek felhasználásával kerül kódolásra. A b_1 bit kerül először továbbításra. Csak a nagybetűk, az „I” és az „O” kivételével vagy az IA-5 „szóköz” használatos.

Referencia pálya adat kiválasztó (RPDS): az a szám-jelzéses azonosító, amely a FAS adat blokk kiválasztására használatos (a kívánt megközelítés).

Megjegyzés. – Egy adott FAS adat blokkra a Referencia pálya adat kiválasztó (RPDS) az összes többi RPDS-től eltérő és minden Referencia állomás adat kiválasztó (RSDS) ugyanazon a frekvencián kerül sugárzásra a rádiósugárzási területen belüli összes GBAS által.

Referencia pálya azonosító: három vagy négy alfanumerikus karakter, amelyek egyedileg jelölik a referencia pályát.

Kódolás: Az egyes karakterek kódolása az 5.sz. Nemzetközi ABC (IA-5) felírása b_1-től b_6-ig terjedő bitjeinek felhasználásával történik. Az egyes karaktereknél a b_1 bit kerül először továbbításra és a b_6 után két kiegészítő nulla bit van, úgy, hogy a nyolc bit minden egyes karakterhez leadásra kerül. Csak a nagybetűk, a számjegyek és az IA-5 „szóköz” használatos. A jobbról a legszélső karakter kerül először leadásra. Egy három-karakteres referencia pálya azonosítóhoz a jobbról a legszélső (az először továbbított) karakternek az IA-5 „szóközének” kell lenni.

Megjegyzés. – Az LTP/FTP egy pont, amelyen keresztül a végső megközelítési szakasz /FAS/ pályája a küszöb keresztezési magasság /TCH/ által meghatározott relatív magasságban áthalad. Ez általában a futópálya középvonalának és a küszöbnek a metszéspontjában helyezkedik el.

LTP/FTP földrajzi szélesség: A Leszállási Küszöb-pont/Látszólagos Küszöb-pont /LTP/FTP/ földrajzi szélessége ív-másodpercben.

Kódolás: A pozitív értékek az északi szélességet jelölik.
A negatív értékek a déli szélességet jelölik.

LTP/FTP földrajzi hosszúság: A Leszállási Küszöb-pont/Látszólagos Küszöb-pont /LTP/FTP/ földrajzi hosszúsága ív-másodpercben.

Kódolás: A pozitív értékek a keleti hosszúságot jelölik.
A negatív értékek a nyugati hosszúságot jelölik.

LTP/FTP magasság: A Leszállási Küszöb-pont/Látszólagos Küszöb-pont /LTP/FTP/ magassága a WGS-84 ellipszoid felett.

Kódolás: Ez a mező egy előjel nélküli fix-pontos számként –512 méteres eltolással kerül kódolásra. Ebben a mezőben egy nulla érték az LTP/FTP-t 512 méterrel a földi ellipszoid alá helyezi.

Megjegyzés. – A Repülési pálya irány-pont /FPAP/ egy pont, amelynek a magassága a Leszállási Küszöb-ponttal/Látszólagos Küszöb-ponttal /LTP/FTP/ azonos, és arra használatos, hogy a megközelítés irányítottságát meghatározza. A szögbeli eltérés kiindulási pontja oldalirányban 305 *méterként (1 000 láb) van meghatározva az FPAP-on az oldalirányú Végső megközelítési szakasz /FAS/ mentén. Egy olyan megközelítésnél, amely a futópályával egy egyenesbe esik, az FPAP a futópálya megállási végénél vagy azon túl van.*

ΔFPAP földrajzi szélesség: A futópálya Repülési pálya irány-pontjának az LTP/FTP-től való fölrajzi szélesség különbsége ív-másodpercben.

Kódolás: A pozitív érték az FPAP földrajzi szélességének az LTP/FTP földrajzi szélességétől északra való helyzetét jelenti.
A negatív érték az FPAP földrajzi szélességének az LTP/FTP földrajzi szélességétől délre való helyzetét jelenti.

ΔFPAP földrajzi hosszúság: A futópálya Repülési pálya irány-pontjának az LTP/FTP-től való fölrajzi szélesség különbsége ív-másodpercben.

Kódolás: A pozitív érték az FPAP földrajzi hosszúságának az LTP/FTP földrajzi hosszúságától keletre való helyzetét jelöli.
A negatív érték az FPAP földrajzi hosszúságának az LTP/FTP földrajzi hosszúságától nyugatra való helyzetét jelöli.

Megközelítési küszöb keresztezési magasság /TCH/: A Végső megközelítési szakasz /FAS/ pályájának magassága az LTP/FTP felett vagy láb-ban, vagy méter-ben meghatározva, ahogy azt a TCH mértékegység kiválasztó jelzi.

Megközelítési küszöb keresztezési magasság mértékegység kiválasztó: A TCH alkalmazott mértékegységének leírása.

Kódolás: 0 = láb
1 = méter

Siklópálya szög (GPA): A Végső megközelítési szakasz pályájának a szöge az LTP/FTP-nél lévő WGS-84 ellipszoidot érintő vízszintes síkhoz viszonyítva.
Útirány szélesség: Az LTP/FTP-nél a Végső megközelítési szakasz által meghatározott repülési pályától való azon oldalirányú eltérés, amelynél az útvonal irány-eltérés jelző a teljes-méretű eltérést eléri.

Kódolás: Ez a mező egy előjel nélküli fix-pontos számként 80 méteres eltolással kerül kódolásra. Ebben a mezőben egy nulla érték az LTP/FTP-nél egy 80 méteres útirány szélességet jelez.

ΔHossz távolság /eltolás/: A futópálya megállási végétől a Repülési pálya irány-pontig /FPAP/ mért távolság.

Kódolás: 1111 1111 = Nincs biztosítva.

Végső megközelítési szakasz Ciklikus Redundancia Ellenőrzés /CRC/: A 32-bites CRC az egyes FAS adat blokkok végéhez van csatolva abból a célból, hogy biztosítsa a megközelítési adatok sértetlenségét. A 32-bites végső megközelítési szakasz CRC-t a 3.9 pontban megadottaknak megfelelően kell kiszámolni. A CRC kód hosszának k = 32 bitnek kell lenni.

A CRC generáló polinomja a következő kell, hogy legyen:

$$G(x) = x^{32} + x^{31} + x^{24} + x^{22} + x^{16} + x^{14} + x^{8} + x^{7} + x^{5} + x^{3} + x + 1$$

A CRC információs mezőjének, M(x), a következőnek kell lenni:

$$M(x) = \sum_{i=1}^{272} m_i x^{272-i} = m_1 x^{271} + m_2 x^{270} + \ldots + m_{272} x^0$$

Az M(x)-t a kapcsolódó FAS adat blokk összes bitjéből kell képezni, a CRC kivételével. A biteket a továbbítási sorrendben kell elrendezni úgy, hogy az m_1 feleljen meg az üzemeltetési típus Legkisebb Helyértékű Bitjének /LSB/, és az m_{272} feleljen meg a Δhossz távolság /eltolás/ mező Legnagyobb Helyértékű Bitjének /MSB/. A CRC-t úgy kell elrendezni, hogy az r_1 legyen az LSB és az r_{32} pedig az MSB.

3.6.4.6 *5. Típusú közlemény – a távolság-meghatározási forrás előre jelzett rendelkezésre állása.* Amikor használatos, akkor az 5. Típusú közleménynek kell magába foglalnia a pillanatnyilag látható, vagy rövidesen láthatóvá váló távolság-meghatározási források ’felkelési’ és ’lenyugvási’ tájékoztatásait. A távolság-meghatározási forrás előre jelzett rendelkezésre állási paramétereinek a következőknek kell lenni:
Módosított Z-számítás: Az ebben a közleményben lévő paraméterek alkalmazhatósági idejének jelzése.

Kódolás: Ugyanaz, mint az 1. Típusú közlemény (3.6.4.2) módosított Z-számítás mezője.

A befogott jelforrások száma: Azoknak a jelforrásoknak a száma, amelyekre az időtartam információ alkalmazható az összes biztosított megközelítésre.

Kódolás: 0 = Csak meghatározott akadályozott megközelítésekre vannak korlátozások.
1-től 31-ig = Az érintett távolság-meghatározási források száma.

Távolság-meghatározási forrás azonosító /ID/: Ugyanaz, mint az 1.Típusú közleménynél (3.6.4.2).

Jel-forrás rendelkezésre állási érzékelés: Azt jelenti, hogy a távolság-meghatározási forrás rendelkezésre állóvá fog-e válni, vagy be fogja fejezni a rendelkezésre állást.

Kódolás: 0 = A differenciális helyesbítések biztosítása a kapcsolódó távolság- meghatározási forrástól rövidesen befejezésre kerül.
1 = A differenciális helyesbítések biztosítása a kapcsolódó távolság- meghatározási forrástól rövidesen megkezdésre kerül.

Jelforrás rendelkezésre állási időtartam: Az előre jelzett minimális rendelkezésre állási időtartam a módosított Z-számításra vonatkoztatva.

Kódolás: 111 1111 = Az időtartam 1 270 másodperccel egyenlő, vagy annál nagyobb.

Az akadályozott megközelítések száma: Azoknak a megközelítéseknek a száma, amelyekre a helyesbítések csökkentésre fognak kerülni a megközelítés egyedülálló műhold helyzet-sor takarása miatt.

Referencia pálya adat kiválasztó: Annak a Végső megközelítési szakasz /FAS/ adatoknak a jelzése, amelyre a jelforrás rendelkezésre állási adatok vonatkoznak (3.6.4.5.1).

A befogott jelforrások száma erre a megközelítésre: Azoknak a jelforrásoknak a száma, amelyeknek az időtartam információja csak erre a megközelítésre alkalmazhatóan van biztosítva.

3.6.7.4 *6. Típusú közlemény*

Megjegyzés. – A 6. Típusú közlemény jövőbeli felhasználásra van fenntartva azon információk biztosításához, amelyek a II./III. kategóriájú precíziós megközelítésekhez szükségesek.

3.6.4.8 *7. Típusú közlemény*

Megjegyzés. – A 7. Típusú közlemény az Államok saját alkalmazásai számára van fenntartva.

3.6.4.9 *8. Típusú közlemény*

Megjegyzés. – A 8. Típusú közlemény helyi és körzeti ellenőrző alkalmazások céljára van fenntartva.

3.6.4.10 *101. Típusú közlemény – GRAS Pszeudo-távolság helyesbítések (PRC)*

3.6.4.10.1 A 101. Típusú közleménynek biztosítania kell a differenciális helyesbítési adatot az egyedi GNSS távolság-meghatározási források számára (B-70A. táblázat). A közleménynek három részből kell állni:

a) közlemény információ (érvényesség ideje, kiegészítő üzenet jelzés, mérések száma és a mérés típusa);

b) alacsony-frekvenciás közlemény (efemerisz dekorrelációs paraméter, műhold efemerisz Ciklikus Redundancia Ellenőrzés (CRC) és műhold rendelkezésre állási közlemény);

c) műhold adat mérési blokkok.

3.6.4.10.2 Minden 101. Típusú közleménynek tartalmaznia kell egy műhold távolság- meghatározási forráshoz tartozó efemerisz dekorrelációs paramétert, efemerisz CRC-t és a forrás rendelkezésre állási időtartam paramétereket. Az efemerisz dekorrelációs paraméter, az efemerisz CRC és a forrás rendelkezésre állási időtartama a közleményben az első távolság- meghatározási forráshoz kell, hogy tartozzon.

3.6.4.10.3 A pszeudó-távolság helyesbítési paramétereknek a következőknek kell lenni:

Módosított Z-számítás: ahogy a 3.6.4.2.3 pontban meghatározásra került.

Kiegészítő közlemény jelző: ahogy a 3.6.4.2.3 pontban meghatározásra került, kivéve, hogy felhasználható a 101. Típusú közleményekre.

Mérések száma: ahogy a 3.6.4.2.3 pontban meghatározásra került.

Mérések típusa: ahogy a 3.6.4.2.3 pontban meghatározásra került.

Efemerisz dekorrelációs tényező (P): ahogy a 3.6.4.2.3 pontban meghatározásra került.

Efemerisz CRC: ahogy a 3.6.4.2.3 pontban meghatározásra került.

Forrás rendelkezésre állási időtartam: ahogy a 3.6.4.2.3 pontban meghatározásra került.

B paraméterek száma: ez egy jelzése annak, hogy a B paramétereket tartalmazza-e az egyes távolság-meghatározási forrás mérési blokkja.

Kódolás: 0 = B paraméterek nincsenek
1 = mérési blokkonként 4 B paraméter van.

3.6.4.10.4 A mérési blokk paramétereknek a következőknek kell lenni:

Távolság-meghatározási forrás azonosító (ID): ahogy a 3.6.4.2.4 pontban meghatározásra került.

Adatkibocsátás (IOD): ahogy a 3.6.4.2.4 pontban meghatározásra került.

Pszeudo-távolság helyesbítés (PRC): ahogy a 3.6.4.2.4 pontban meghatározásra került.

Távolság-meghatározási változás helyesbítés (RRC): ahogy a 3.6.4.2.4 pontban meghatározásra került.

σ_{pr_gnd} : ahogy a 3.6.4.2.4 pontban meghatározásra került, az értékek és a felbontási tartomány kivételével.

B_1 –től a B_4-ig: ahogy a 3.6.4.2.4 pontban meghatározásra került.

Megjegyzés. – A 101. Típusú közleményeknél a mérési blokkban a B paraméterek szerepeltetése opcionális.

3.6.5 AZ ADATFELHASZNÁLÓI PROTOKOLOK MEGHATÁROZÁSA

Megjegyzés. – Ez a rész az adat sugárzási közlemények paraméterei közötti kölcsönhatást határozza meg. Ez azoknak a paramétereknek a meghatározásait adja meg, amelyek nem kerülnek továbbításra, de a nem-légijármű fedélzeti és a légijármű fedélzeti elemek valamelyikében, vagy mindkettőben használatosak, és amelyek meghatározzák azokat a tényezőket, amelyek a navigációs megoldásokra és azok sértetlenségére vonatkoznak.

3.6.5.1 *Mért és vivőhullám-simított pszeudo-távolság.* A sugárzási helyesbítés vivőhullám-simított kódú pszeudo-távolság mérésként alkalmazható úgy, hogy még nem kerül a műhold által sugárzott troposzférikus és ionoszférikus helyesbítés alkalmazásra. A vivőhullám-simítást a következő szűrő határozza meg:

$$P_{CSCn} = \alpha P + (1-\alpha)\left(P_{CSC_{n-1}} + \frac{\lambda}{2\pi}(\phi_n - \phi_{n-1})\right)$$

ahol:

P_{CSCn}	=	A simított pszeudo-távolság;
P_{CSCn-1}	=	A korábbi simított pszeudo-távolság;
P	=	A nyers pszeudo-távolság mérés, ahol a nyers pszeudo-távolság méréseket egy, a vivőhullám által meghajtott kód hurokból mérik elsőrendűen, vagy magasabban, és egy olyan egyoldalú zaj sávszűrővel, ami 0,125 Hz-el egyenlő, vagy annál magasabb értékű;
λ	=	Az L1 hullámhossza;
ϕ_n	=	A vivőhullám fázisa;
ϕ_{n-1}	=	Az előző vivőhullám fázisa; és
α	=	A szűrő súlyozási függvénye egyenlő a 100 másodperces idő-állandóval elosztott mintavételi időközzel.

3.6.5.2 *Helyesbített pszeudo-távolság.* Egy adott műholdra a ’t’ időben a helyesbített pszeudo-távolság a következő:

$$PRcorrected = P_{CSC} + PRC + RRC \times (t - tz\text{-}count) + TC + c \times (\Delta t_{SV})_{L1}$$

ahol:

P_{CSC}	=	A simított pszeudo-távolság (a 3.6.5.1 pontban meghatározottak szerint);
PRC	=	A pszeudo-távolság helyesbítés (a 3.6.4.2 pontban meghatározottak szerint);
RRC	=	A pszeudo-távolság helyesbítés gyakorisága (a 3.6.4.2 pontban meghatározottak szerint);
t	=	Az aktuális /pillanatnyi/ idő;
tz-count	=	Az alkalmazhatóság ideje a módosított Z-számításból levezetve (a 3.6.4.2 pontban meghatározottak szerint); és
TC	=	A troposzférikus helyesbítés (a 3.6.5.3 pontban meghatározottak szerint).
c és Δt_{SV}	=	Ahogy a 3.1.2.2 pontban meg van határozva a GPS műholdak számára.

3.6.5.3 *Troposzférikus késés*

3.6.5.3.1 Egy adott műholdra a troposzférikus helyesbítés a következő:

$$TC = N_r h_0 \frac{10^{-6}}{\sqrt{0.002 + \sin^2(El_i)}} (1 - e^{-\Delta h / h_0})$$

ahol:

N_R	=	A törési index a 2. Típusú közleményből (3.6.4.3);
Δh	=	A légijármű magassága a GBAS referencia pont felett;
El_i	=	Az i-dik műhold magassági szöge; és
h_0	=	A troposzféra skála magassága a 2. Típusú közleményből.

3.6.5.3.2 A megmaradó troposzférikus bizonytalanság a következő:

$$\sigma_{tropo} = \sigma_n h_0 \frac{10^{-6}}{\sqrt{0.002 + \sin^2(El_i)}} (1 - e^{-\Delta h / h_0})$$

ahol: σ_N = A törési bizonytalanság a 2. Típusú közleményből (3.6.4.3).

3.6.5.4 *A megmaradó ionoszférikus bizonytalanság.* Egy adott műholdra a megmaradó ionoszférikus bizonytalanság a következő:

$$\sigma_{iono} = F_{pp} \times \sigma_{vert\_iono\_gradient} \times (x_{air} + 2 \times \tau \times v_{air})$$

ahol:

F_{pp}	=	A függőlegestől a ferdéig terjedő elhajlási tényező egy adott műholdra (3.5.5.5.2);
$\sigma_{vert\_iono\_gradient}$	=	(ahogy a 3.6.4.3 pontban meghatározásra került);
x_{air}	=	A távolság (ferde távolság) méterben a légijármű pillanatnyi helyzete és a 2. Típusú közleményben megadott referencia pont között;
τ	=	100 másodperc (a 3.6.5.1 pontban használt idő-állandó); és
v_{air}	=	A légijármű vízszintes megközelítési sebessége (méter/másodperc)

3.6.5.5 *Védelmi szintek*

3.6.5.5.1 *I.kategóriájú precíziós megközelítés.* A térbeli-jel függőleges és oldalirányú védelmi szintjei (a VPL és LPL) felső megbízhatósági határértékek a referencia ponthoz viszonyított helyzet hibára, és ezek meghatározása a következő:

$$VPL = MAX\ \{VPL_{HO}, VPL_{H1}\}$$
$$LPL = MAX\ \{LPL_{HO}, LPL_{H1}\}$$

3.6.5.5.1.1 *Szabvány mérési körülmények*

3.6.5.5.1.1.1 A függőleges védelmi szint (VPL_{H0}) és az oldalirányú védelmi szint (LPL_{H0}) feltételezve azt, hogy szabvány mérési körülmények állnak fenn (azaz nincs hiba), az összes referencia vevőben és az összes távolság-meghatározási forráson (műholdak), a következők szerint kerülnek kiszámításra:

$$VPL_{H0} = K_{ffmd}\sqrt{\sum_{i=1}^{N} s\_vert_i^2 \times \sigma_i^2}$$

$$LPL_{H0} = K_{ffmd}\sqrt{\sum_{i=1}^{N} s\_lat_i^2 \times \sigma_i^2}$$

ahol:

K_{ffmd}, Cat I.	=	Az a szorzó, ami a hibamentes kimaradt észlelés valószínűségéből került levezetésre;
s_vert_i	=	$s_{v,i} + s_{x,i} \times \tan(GPA)$ /Siklópálya szög/;
s_lat_i	=	$s_{y,i}$;
$s_{x,i}$	=	Az x-irányú helyzet hiba parciális differenciál-hányadosa az i-dik műhold pszeudo-távolság hibájára vonatkozóan;
$s_{y,i}$	=	Az y-irányú helyzet hiba parciális differenciál-hányadosa az i-dik műhold pszeudo-távolság hibájára vonatkozóan;
$s_{v,i}$	=	A függőleges irányú helyzet hiba parciális differenciál-hányadosa az i-dik műhold pszeudotávolság hibájára vonatkozóan;
GPA	=	A végső megközelítési pálya siklópálya szöge (3.6.4.5.1);
N	=	A helyzet-megoldáshoz használt távolság-meghatározási források száma; és
i	=	A helyzet-megoldáshoz használt távolság-meghatározási forrás indexe.

Megjegyzés. – A koordináta vonatkoztatási rendszer úgy van meghatározva, hogy az ’x’ az út-irány mentén pozitív, az ’y’ keresztirányban balra pozitív, a helyi szint érintő síkjában és a ’v’ felfelé pozitív és derékszögű az x- és y-tengelyre.

3.6.5.5.1.1.2 Az általános-legkisebb-négyzetek helyzet megoldásra az ’S’, a vetület-mátrix a következők szerint van meghatározva:

$$S \equiv \begin{bmatrix} S_{x,1} & S_{x,2} & \cdots & S_{x,N} \\ S_{y,1} & S_{y,2} & \cdots & S_{y,N} \\ S_{v,1} & S_{v,2} & \cdots & S_{v,N} \\ S_{t,1} & S_{t,2} & \cdots & S_{t,N} \end{bmatrix} = (G^T \times W \times G)^{-1} \times G^T \times W$$

ahol:

$G_i = [\ -\cos El_i \cos Az_i\ \ -\cos El_i \sin Az_i\ \ -\sin El_i\ \ 1\ ]$ = a G i-dik sora; és

$$W = \begin{bmatrix} \sigma_1^2 & 0 & \cdots & 0 \\ 0 & \sigma_2^2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \sigma_N^2 \end{bmatrix}^{-1};$$

Ahol: $\sigma^2{}_i = \sigma^2{}_{pr\_gnd,i} + \sigma^2{}_{tropo,i} + \sigma^2{}_{pr\_air,i} + \sigma^2{}_{iono,i}$;

ahol:

$\sigma_{pr\_gnd,i}$	=	σ_{pr_gnd} az i-dik távolság-meghatározási forrásra (3.6.4.2);
$\sigma_{tropo,i}$	=	A megmaradó troposzférikus bizonytalanság az i-dik távolság-meghatározási forrásra (3.6.5.3);
$\sigma_{iono,i}$	=	A megmaradó ionoszférikus késés (a térbeli dekorreláció miatt) az i-dik távolság-meghatározási forrásra (3.6.5.4); és
$\sigma_{pr\_air,i}$	=	$\sqrt{\sigma^2_{receiver}(El_i) + \sigma^2_{multipath}(El_i)}$, az a szabvány eltérés, amellyel a légijármű hozzájárul az i-dik távolság-meghatározási forrás helyesbített pszeudo-távolság hibájához. A teljes légijármű hozzájárulás magába foglalja a vevő hozzájárulását (3.6.8.2.1) és egy szabvány hiba értéket a légijármű szerkezetének térbeli szórása miatt;

Ahol:

$\sigma_{multipath,i}(El_i)$	=	$0{,}13 + 0{,}53e^{-El_i/10\ deg}$, a légijármű sárkány térbeli szórási hozzájárulásának szabvány modelje méterben megadva;
El_i	=	Az i-dik távolság-meghatározási forrás magassági szöge (fokban megadva); és
Az_i	=	Az i-dik távolság-meghatározási forrás oldalszöge az x-tengelytől az óramutató járásával ellentétes irányban mérve (fokban megadva).

Megjegyzés. – Az olvashatóság növelése érdekében az 'i' *index kihagyásra került a vetület mátrix egyenletből.*

3.6.5.5.1.2 *Hibás mérési körülmények.* Amikor a 101. Típusú közleményt B paraméter blokkok nélkül sugározzák, a függőleges védelmi szint (VPL_{H1}) és az oldalirányú védelmi szint (LPL_{H1}) 0-nak van meghatározva. Más esetekben, a függőleges védelmi szint (VPL_{H1}) és az oldalirányú védelmi szint (LPL_{H1}) meghatározása - feltételezve azt, hogy az egyikben egy rejtett hiba áll fenn és csak egy referencia vevő van – a következő:

$$VPL_{H1} = \max.\ [VPL_j]$$
$$LPL_{H1} = \max.\ [LPL_j]$$

Ahol a VPL_j és az LPL_j a j-re = 1-től 4-ig

$VPL_j = |\ B\_vert_j\ | + K_{mdCat\ I.}\ \sigma_{vert,H1}$ és
$LPL_j = |\ B\_lat_j\ | + K_{md\ Cat\ I.}\ \sigma_{lat,H1}$ és

és

$$B\_vert_j = \sum_{i=1}^{N} (s\_vert_i \times B_{i,j});$$

$$B\_lat_j = \sum_{i=1}^{N} (s\_lat_i \times B_{i,j});$$

$B_{i,j}$ = A sugárzási különbségek a pszeudo-távolság helyesbítések sugárzása és a megszerzett helyesbítések sugárzása között, kizárva a j-dik referencia vevő méréseit az i-dik távolság-meghatározási forrásra;

K_{mdCatI}. = A kimaradt észlelés valószínűségéből levezetett szorzó, ha adott az, hogy a földi al-rendszer hibás;

$$\sigma^2_{vert,H1} = \sum_{i=1}^{N} (s\_vert^2_i \times \sigma\_H1^2_i);$$

$$\sigma^2_{lat,H1} = \sum_{i=1}^{N} (s\_lat^2_i \times \sigma\_H1^2_i);$$

$$\sigma\_H1^2_i = \left(\frac{M_i}{U_i}\right)\sigma^2_{pr\_gnd,i} + \sigma^2_{pr\_air,i} + \sigma^2_{tropo,i} + \sigma^2_{iono,i};$$

M_i = Azoknak a referencia vevőknek a száma, amelyek az i-dik távolság-meghatározási forrás pszeudo-távolság helyesbítésének kiszámításához használatosak (a ’B’ érték által jelzetten); és

U_i = Azoknak a referencia vevőknek a száma, amelyek az i-dik távolság-meghatározási forrás pszeudo-távolság helyesbítésének kiszámí-tásához használatosak, a j-dik referencia vevőt kizárva.

Megjegyzés. – A rejtett hiba magába foglal minden olyan hibás mérést, amit a földi rendszer nem azonnal észlel, így a sugárzott adatok érintettek, és így egy előidézett helyzet hiba áll fenn a légijármű fedélzeti al-rendszerében.

3.6.5.5.1.3 *A K-szorzók meghatározása az I. kategóriájú precíziós megközelítésekre.* A szorzók a B-67. táblázatban kerültek megadásra.

3.6.5.5.2 *GBAS helymeghatározási szolgáltatás.* A térbeli-jel vízszintes védelmi szintje egy felső megbízhatósági határérték a referencia ponthoz viszonyított vízszintes helyzet hibára és a meghatározása:

$$HPL = MAX\ \{HPL_{H0}, HPL_{H1}\}$$

B-67. táblázat: K-szórzók az I. kategóriájú precíziós megközelítéshez és APV

Szorzó	M_i			
	1 (Megjegyzés)	2	3	4
K_{ffmd}	6,86	5,762	5,81	5,847
K_{md}	Nincs használva	2,935	2,898	2,878

Megjegyzés. – APV I-es megközelítésekhez, amit a 101. Típusú közlemény sugárzások támogatnak ’B’ paraméter blokk nélkül.

3.6.5.5.2.1 *Szabvány mérési körülmények.* A vízszintes védelmi szint (HPL_{H0}) feltételezve azt, hogy szabvány mérési körülmények állnak fenn (azaz nincs hiba) az összes referencia vevőben és az összes távolság-meghatározási forráson, a következők szerint kerül kiszámításra:

$$HPL_{H0} = K_{ffmd,\ POS}\ d_{major}$$

ahol:

$$d_{major} = \sqrt{\frac{d_x^2 + d_y^2}{2} + \sqrt{\left(\frac{d_x^2 - d_y^2}{2}\right)^2 + d_{xy}^2}}$$

$$d_x^2 = \sum_{i=1}^{N} s_{x,i}^2 \sigma_i^2$$

$$d_y^2 = \sum_{i=1}^{N} s_{y,i}^2 \sigma_i^2$$

$$d_{xy} = \sum_{i=1}^{N} s_{x,i} s_{y,i} \sigma_i^2$$

$s_{x,i}$	=	Az x-irányú helyzet hiba parciális differenciál-hányadosa az i-dik műhold pszeudo-távolság hibájára vonatkozóan;
$s_{y,i}$	=	Az y-irányú helyzet hiba parciális differenciál-hányadosa az i-dik műhold pszeudo-távolság hibájára vonatkozóan;
K_{ffmd}, PosI.	=	Az a szorzó, ami a hibamentes kimaradt észlelés valószínűségéből került levezetésre;
N	=	A helyzet-megoldáshoz használt távolság-meghatározási források száma;
i	=	A helyzet-megoldáshoz használt távolság-meghatározási források távolság-meghatározási forrás indexe;
σi	=	A pszeudo-távolság hiba tényező, ahogy az a 3.6.5.5.1.1 pontban meghatározásra került.

Megjegyzés. – A GBAS helymeghatározási szolgáltatásra az x- és y-tengelyek egy önkényes derékszögű alapot határoznak meg a vízszintes síkban.

3.6.5.5.2.2 *Hibás mérési körülmények.* Amikor a 101. Típusú közleményt B paraméter blokkok nélkül sugározzák, a vízszintes védelmi szint (HPL_{H1}) 0-nak van meghatározva. Más esetekben, a vízszintes védelmi szint (HPL_{H1}), feltételezve azt, hogy egy rejtett hiba áll fenn az egyikben és csak egy referencia vevő van, a következő:

$$HPL_{H1} = \max\ [HPL_j\ ]$$

ahol a HPL_j a j-re = 1-től 4-ig:

$$HPL_j = |\ B\_horz_j\ | + K_{md\_POS}\ d_{major,\ H1}$$

és

$$B\_horz_j = \sqrt{\left(\sum_{i=1}^{N} S_{x,i} B_{i,j}\right)^2 + \left(\sum_{i=1}^{N} S_{y,i} B_{i,j}\right)^2}$$

$B_{i,j}$ = a sugárzási különbségek a pszeudo-távolság helyesbítés sugárzása és a megszerzett helyesbítések között, kizárva a j-dik referencia vevő méréseit az i-dik távolság-mérési forrásra.
K_{md_POS} = a kimaradt észlelés valószínűségéből levezetett szorzó, feltéve, hogy a földi al-rendszer hibás.

$$d_{major,H1} = \sqrt{\frac{d\_H1_x^2 + d\_H1_y^2}{2} + \sqrt{\left(\frac{d\_H1_x^2 - d\_H1_y^2}{2}\right)^2 + d\_H1_{xy}^2}}$$

$$d\_H1_x^2 = \sum_{i=1}^{N} s_{x,i}^2 \sigma\_H1_i^2$$

$$d\_H1_y^2 = \sum_{i=1}^{N} s_{y,i}^2 \sigma\_H1_i^2$$

$$d\_H1_{xy} = \sum_{i=1}^{N} s_{x,i} s_{y,i} \sigma\_H1_i^2$$

Megjegyzés. – A GBAS helymeghatározási szolgáltatásra az x- és y-tengelyek egy önkényes derékszögű alapot határoznak meg a vízszintes síkban.

$$\sigma\_H1_i^2 = \left(\frac{M_i}{U_i}\right)\sigma_{pr\_gnd,i}^2 + \sigma_{pr\_air,i}^2 + \sigma_{tropo,i}^2 + \sigma_{iono,i}^2$$

M_i = Azoknak a referencia vevőknek a száma, amelyek az i-dik távolság-meghatározási forrás pszeudo-távolság helyesbítésének kiszámításához használatosak (a ’B’ érték által jelzetten).
U_i = Azoknak a referencia vevőknek a száma, amelyek az i-dik távolság-meghatározási forrás pszeudo-távolság helyesbítésének kiszámításához használatosak, a j-dik referencia vevőt kizárva.

Megjegyzés. – A rejtett hiba magába foglal minden olyan hibás mérést, amit a földi rendszer nem azonnal észlel, úgy, hogy a sugárzott adatok érintettek, és így egy előidézett helyzet hiba áll fenn a légijármű fedélzeti al-rendszerében.

3.6.5.5.2.3 *A K-szorzók meghatározása a Földi Bázisú Kiegészítő Rendszer /GBAS/ helymeghatározási szolgáltatásra.* A K_{ffmd_POS} szorzó 10-el egyenlő és a K_{md_POS} szorzó 5,3-el egyenlő.

3.6.5.6 *Riasztási határértékek*

Megjegyzés. – A riasztási határértékek számításával kapcsolatos útmutató, beleértve a 40 000-től 99 999-ig terjedő csatorna számokhoz kapcsolódó megközelítéseket, a”D”- Melléklet 7.13 pontjában került megadásra.

3.6.5.6.1 *Az I. kategóriájú precíziós megközelítés riasztási határértékei.* A riasztási határértékek a B-68. és a B-69. táblázatban kerültek meghatározásra. Azokra a légijármű helyzetekre, amelyeknél az oldalirányú eltérés kétszer meghaladja azt az eltérést, amelynél az irány-eltérés jelző műszer a teljes skálájú oldalirányú eltérést eléri, vagy a függőleges eltérés kétszer meghaladja azt az eltérést, amelynél az irány-eltérés jelző műszer a teljes skálájú siklópálya-alatt eltérést eléri, a táblázatban mindkét, az oldalirányú és a függőleges riasztási határértékek maximális értékként vannak megadva.

3.6.5.6.2 *APV riasztási határértékek*. A 20 001 és 39 999 közötti csatorna szám tartományban lévő megközelítéseknél a riasztási határértékek a Végső megközelítési szakasz Oldalirányú riasztási határérték (FASLAL) és a Végső megközelítési szakasz Függőleges riasztási határérték (FASVAL) értékekkel egyeznek meg. A 40 000 és 99 999 közötti csatorna számú megközelítéseknél a riasztási határértékeket a fedélzeti adatbázisban tárolják.

3.6.5.7 *Csatorna szám*. Minden egyes GBAS megközelítéshez kapcsolódik egy csatorna szám a 20 001-től a 39 999-ig terjedő tartományban. Ha kiosztásra kerül, akkor a GBAS helymeghatározási szolgáltatáshoz társítva van egy különálló csatorna szám, a 20 001-től a 39 999-ig terjedő tartományban. A csatorna számot az alábbi kifejezés adja meg:

$$\text{Csatorna szám} = 20\,000 + 40(F - 108{,}0) + 411(S)$$

ahol:

F = adat sugárzási frekvencia (MHz); és
S = RPDS, vagy RSDS

és

RPDS = a referencia pálya adat kiválasztó a végső megközelítési szakasz /FAS/ adat blokkjához (ahogy az a 3.6.4.5.1 pontban meghatározásra került)
RSDS = referencia állomás adat kiválasztó a GBAS földi al-rendszerhez (ahogy az a 3.6.4.3.1 pontban meghatározásra került)

A 2. Típusú közlemény 2. adatblokkjában kisugárzott csatorna számok esetében (ahogy a 3.6.4.3.2.1 pontban meghatározásra került), csak az RSDS-ket használják.

B-68. táblázat: I. Kategóriájú Oldalirányú riasztási határérték

A légijármű helyzetének vízszintes távolsága az LTP/FTP-től, ahogy az végighalad a végső megközelítési pályán (méter)	Oldalirányú riasztási határérték (méter)
291 < D ≤ 873	FASLAL
873 < D ≤ 7 500	0,0044D(m) + FASLAL-3,85
D > 7 500	FASLAL + 29,15

LTP = Leszállási küszöb-pont
FTP = Látszólagos küszöb-pont
FASLAL = Végső megközelítési szakasz Oldalirányú riasztási határérték

B-69. táblázat: Függőleges riasztási határérték

A légijármű helyzetének az LTP/FTP feletti magassága, ahogy az a végső megközelítési pálya felé halad (láb)	Függőleges riasztási határérték (méter)
100 < H ≤ 200	FASVAL
200 < H ≤ 1 340	0, 02925H(láb) + FASVAL-5,85
H > 1 340	FASVAL + 33,35

LTP = Leszállási küszöb-pont
FTP = Látszólagos küszöb-pont
FASVAL = Végső megközelítési szakasz Függőleges riasztási határérték

1. Megjegyzés. – Amikor egy APV számára nem kerül kiadásra a FAS, a GBAS megközelítés a 40 000 és 99 999 közötti csatorna számhoz fog kapcsolódni.

2. Megjegyzés. – A csatorna szám kiválasztáshoz kapcsolódó útmutató a "D"- Melléklet 7.7 pontjában került megadásra.

3.6.5.8 Efemerisz-hiba helyzet határ.

Megjegyzés. – Az efemerisz-hiba helyzet határok csak a helyzet megoldásban (j index) használt műhold helyzetsor rendszerű távolság-mérési forrásokra kerülnek kiszámításra és más típusú távolság-mérési forrásokra nem, (Műhold Bázisú Kiegészítő Rendszer műholdakra, vagy pszeudolitekre) azokra, amelyek nincsenek kitéve a kimutathatatlan efemerisz-hibáknak. Azonban ezeknek a helyzet határoknak a kiszámításai felhasználják a helyzet megoldásban (i index) felhasznált összes távolság-mérési forrástól eredő információkat.

3.6.5.8.1 *I. kategóriájú precíziós megközelítés és APV.* A függőleges és oldal-irányú efemerisz-hiba helyzet határok a következők szerint kerülnek meghatározásra:

$$VEB = \underset{j}{MAX}\,\{VEB_j\}$$

$$LEB = \underset{J}{MAX}\,\{LEB_j\}$$

A függőleges és oldalirányú efemerisz-hiba helyzet határokat a helyzet megoldásban használatos j-dik műhold helyzetsor rendszerű távolság-mérési forrásra a következő képlet adja meg:

$$VEB_j = \left|s\_vert_j\right| x_{air} P_j + K_{md\_e,j}\sqrt{\sum_{i=1}^{N} s\_vert_i^2 \times \sigma_i^2}$$

$$LEB_j = \left|s\_lat_j\right| x_{air} P_j + K_{md\_e,j}\sqrt{\sum_{i=1}^{N} s\_lat_i^2 \times \sigma_i^2}$$

ahol:

$s\_vert_{i \text{ vagy } j}$ ahogy az a 3.6.5.5.1.1 pontban meghatározásra került
$s\_lat_{i \text{ vagy } j}$ ahogy az a 3.6.5.5.1.1 pontban meghatározásra került

x_{air} ahogy az 3.6.5.4 pontban meghatározásra került
N a helyzet megoldásban használatos távolság-mérési források száma
σ_i ahogy az a 3.6.5.5.1.1 pontban meghatározásra került
P_j a sugárzott efemerisz dekorrelációs paraméter a j-dik távolság-mérési forrásra
$K_{md\_e\_CATI}$ a sugárzott, a műhold helyzet-sor rendszerhez kapcsolódó efemerisz hibás észlelési szorzó a precíziós megközelítésre a j-dik távolság-mérési forrásra ($K_{md\_e\_CATI, GPS}$ vagy $K_{md\_e\_CATI, GLONASS}$)

3.6.5.8.2 *Földi Bázisú Kiegészítő Rendszer /GBAS/ helymeghatározási szolgáltatás.* A vízszintes efemerisz-hiba helyzet határt a következő képlet adja meg:

$$HEB = \underset{j}{MAX}\{HEB_j\}$$

A vízszintes efemerisz-hiba helyzet határt a helyzet megoldásban használatos j-dik műhold helyzetsor rendszerű távolság-mérési forrásra a következő képlet adja meg:

$$HEB_j = \left|s_{horz,j}\right| x_{air} P_j + K_{md\_e\_POS}\, d_{major}$$

ahol:

$s_{horz,j}^2 =$ $s_{xj}^2 + s_{yj}^2$
$s_{x,j}$ ahogy az 3.6.5.5.2.1 pontban meghatározásra került
$s_{y,j}$ ahogy az 3.6.5.5.2.1 pontban meghatározásra került
x_{air} a 3.6.5.4 pontban került meghatározásra
P_j a sugárzott efemerisz dekorrelációs paraméter a j-dik távolság-mérési forrásra
$K_{md\_e\_POS}$ a sugárzott, a műhold helyzetsor rendszerhez kapcsolódó hibás észlelési szorzó a GBAS helymeghatározási szolgáltatásra a j-dik távolság-mérési forrásra ($K_{md\_e\_POS, GPS}$ vagy $K_{md\_e\_POS, GLONASS}$)
d_{major} a 3.6.5.5.2.1 pontban került meghatározásra

3.6.6 KÖZLEMÉNY TÁBLÁZATOK

Minden egyes GBAS közleményt a B-70. táblázattól a B-73. táblázatig terjedően meghatározott megfelelő közlemény formátummal megegyezően kell kódolni.

Megjegyzés. – A közlemény típus szerkezete a 3.6.4.1 pontban került meghatározásra.

3.6.7 NEM-LÉGIJÁRMŰ FEDÉLZETI ALKOTÓ-ELEMEK

3.6.7.1 *Teljesítmény*

3.6.7.1.1 *Pontosság*

3.6.7.1.1.1 A GPS és GLONASS műholdak helyesbített pszeudo-távolság paramétereihez a földi alrendszer hozzájárulásának négyzetes közép-értéke (RMS) (1 szigma) a következő kell, hogy legyen:

$$RMS_{pr\_gnd} \le \sqrt{\frac{(a_0 + a_1 e^{-\theta_n/\theta_0})^2}{M} + (a_2)^2}$$

ahol:

M	=	A telepített földi referencia vevők száma;
n	=	Az n-dik távolság-meghatározási forrás;
θ_n	=	Az n-dik távolság-meghatározási forrás magassági szöge;
a_0, a_1, a_2, és a θ_0	=	A B-73. és a B-74. táblázatban meghatározott paraméterek mindegyike, ahogy a földi pontossági jelölésekre (GAD-k) meghatározásra kerültek.

1. Megjegyzés. – A GBAS földi al-rendszer pontossági követelményét a földi pontossági jelölés /GAD/ betűk és a telepített referencia vevők száma határozza meg.

2. Megjegyzés. – A helyesbített pszeudo-távolság hibához a GBAS földi al-rendszer hozzájárulását a B-74. és B-75. táblázatokban megadott görbék határozzák meg, és az SBAS műholdak hozzájárulása nem foglalja magába a légijármű berendezés zajt és a légijármű szerkezete miatti többutas terjedést.

B-70. táblázat: Az 1. Típusú pszeudo-távolság helyesbítések közleménye

Adat tartalom	Felhasznált bitek	Érték tartomány	Felbontás
Módosított Z-számítás	14	0-tól 1 199,9 s-ig	0,1 s
Kiegészítő közlemény jelző	2	0-tól 3-ig	1

3.6.7.1.1.2 Az SBAS műholdak helyesbített pszeudo-távolság pontosságában a földi al-rendszer hozzájárulásának négyzetes középértéke /RMS/ a következő kell, hogy legyen:

$$RMS_{pr\_gnd} \leq \frac{1{,}8}{\sqrt{M}} \quad \text{(méter)}$$

ahol:
M értéke annyi, ahogy a 3.6.7.1.1.1 pontban meghatározásra került.

Megjegyzés. – Az SBAS távolság-meghatározási források Földi pontossági jelölése /GAD/ kidolgozás alatt áll.

3.6.7.1.2 *Sértetlenség*

3.6.7.1.2.1 *A GBAS földi al-rendszerek sértetlenségi veszélye*

3.6.7.1.2.1.1 *I. kategóriájú precíziós megközelítés.* Annak a GBAS földi al-rendszernek, amely I. kategóriájú precíziós megközelítést biztosít, a sértetlenségi veszélye megközelítésenként 1,5 x 10^{-7} -nél kisebb, kell, hogy legyen.

1. Megjegyzés. – A GBAS földi al-rendszerre meghatározott sértetlenségi veszély a GBAS térbeli-jel sértetlenségi veszély egy olyan rész-halmaza, ahol kizárásra került a védelmi szint sértetlenségi veszélye (3.6.7.1.2.2.1) és az összes egyéb GBAS, SBAS és állandó pályájú műhold rendszer hibáknak a hatása kerül beszámításra. A GBAS földi al-rendszer sértetlenségi veszélye magába foglalja a 3.6.7.2.6 pont szerinti megkívánt műhold jel ellenőrzés sértetlenségi veszélyét és a 3.6.7.3 pontnak az ellenőrzéshez kapcsolódó sértetlenségi veszélyét.

2. Megjegyzés. – A GBAS térbeli-jel sértetlenségi veszély úgy került meghatározásra, mint annak a valószínűsége, hogy a földi al-rendszer olyan információkat biztosít, amelyek amikor egy olyan hiba-mentes vevővel kerülnek feldolgozásra, ami bármilyen, a légijármű által felhasználható GBAS adatot használ fel, akkor azok egy, a tűréshatáron kívüli oldalirányú, vagy függőleges relatív helyzet hibát *eredményeznek (hiba) kijelzés nélkül a maximális „idő-a-riasztásig” időtartamnál hosszabb ideig. Egy tűréshatáron kívüli oldalirányú, vagy függőleges relatív helyzet hiba úgy került meghatározásra, hogy ez az a hiba, ami meghaladja mind az I. kategóriájú precíziós megközelítés védelmi szintjét, mind – ha a kiegészítő 1. adatblokk sugárzásra kerül – az efemerisz-hiba helyzet határt.*

3.6.7.1.2.1.1.1 A GBAS földi al-rendszer maximális „idő – a – riasztásig” időtartamának 3 másodpercnek, vagy annál kevesebbnek kell lenni.

Megjegyzés. – A fenti az „idő – a – riasztásig” az az időtartam, ami a tűréshatáron kívüli oldalirányú, vagy függőleges relatív helyzet hiba kezdete és annak a közleménynek az utolsó bitje sugárzási ideje között van, ami a helyzetet tükröző sértetlenségi adatokat magába foglalja.

3.6.7.1.2.1.1.2 A GBAS földi al-rendszer maximális „idő – a – riasztásig” időtartamának 5,5 másodpercnek, vagy annál kevesebbnek kell lenni, amikor 101. Típusú közlemény kiadása történik.

3.6.7.1.2.1.1.3 Az I. Kategóriájú Végső megközelítési szakasz /FAS/ blokkokban a Végső megközelítési szakasz Oldalirányú riasztási határérték /FASLAL/ értékének, ahogy az a 4. Típusú közlemény FAS Oldalirányú riasztási határérték mezőben meghatározásra került, nem több, mint 40 méternek kell lenni. Az egyes Végső megközelítési szakasz /FAS/ blokkokban a Végső megközelítési szakasz Függőleges riasztási határérték /FASVAL/ értékének, ahogy az a 4. Típusú közlemény FAS Függőleges riasztási határérték mezőben meghatározásra került, nem több, mint 10 méternek kell lenni.

3.6.7.1.2.1.1.4 Megközelítés Függőleges Vezetéssel (APV) esetén a Végső megközelítési szakasz Oldalirányú riasztási határérték /FASLAL/ és a Végső megközelítési szakasz Függőleges riasztási határérték /FASVAL/ értéke nem lehet nagyobb, mint az Annex 10, I. Kötet 3.7.2.4 pontban megadott oldalirányú és függőleges riasztási határérték.

3.6.7.1.2.1.2 *GBAS helymeghatározási szolgáltatás*. A GBAS földi al-rendszernek, amely GBAS helymeghatározási szolgáltatást biztosít, a sértetlenségi veszélye óránként $9{,}9 \times 10^{-8}$ -nál kisebb, kell, hogy legyen.

1. Megjegyzés. – A GBAS földi al-rendszerre meghatározott sértetlenségi veszély a GBAS térbeli-jel sértetlenségi veszély egy olyan rész-halmaza, ahol kizárásra került a védelmi szint sértetlenségi veszélye (3.6.7.1.2.2.1) és az összes egyéb GBAS, SBAS és állandó pályájú műhold rendszer hibáknak a hatása kerül beszámításra. A GBAS földi al-rendszer sértetlenségi veszélye magába foglalja a 3.6.7.2.6 pont szerinti megkívánt műhold jel ellenőrzés sértetlenségi veszélyét és a 3.6.7.3 pontnak az ellenőrzéshez kapcsolódó sértetlenségi veszélyét.

2. Megjegyzés. – A GBAS térbeli-jel sértetlenségi veszély úgy került meghatározásra, mint annak a valószínűsége, hogy a földi al-rendszer olyan információkat biztosít, amelyek amikor egy olyan hiba-mentes vevővel kerülnek feldolgozásra, ami bármilyen, a légijármű által felhasználható GBAS adatot használ fel, akkor azok egy, a tűréshatáron kívüli oldalirányú vagy függőleges relatív helyzet hibát eredményeznek (hiba) kijelzés nélkül a maximális „idő-a-riasztásig” időtartamnál hosszabb ideig. Egy tűréshatáron kívüli oldalirányú vagy függőleges relatív helyzet hiba úgy került meghatározásra, hogy az az a hiba, ami meghaladja mind a vízszintes védelmi szintet, mind a vízszintes efemerisz-hiba helyzet határt.

3.6.7.1.2.1.2.1 A GBAS földi al-rendszer maximális „idő – a – riasztásig” időtartamának 3 másodpercnek, vagy annál kevesebbnek kell lenni, amikor 1. Típusú közlemény kiadása történik, és 5,5 másodpercnek, vagy annál kevesebbnek kell lenni, amikor 101. Típusú közlemény kiadása történik.

Megjegyzés. – A fenti az „idő – a – riasztásig” az az időtartam, ami a tűréshatáron kívüli oldalirányú, vagy függőleges relatív helyzet hiba kezdete és annak a közleménynek az utolsó bitje sugárzási ideje között van, ami a helyzetet tükröző sértetlenségi adatokat magába foglalja.

3.6.7.1.2.2 *Védelmi szint sértetlenségi veszély*

3.6.7.1.2.2.1 Annak a GBAS földi al-rendszernek, amely I. kategóriájú precíziós megközelítést, vagy APV-t biztosít, a védelmi szint sértetlenségi veszélyének megközelítésenként 5 x 10^{-8}-nál kevesebbnek kell lenni.

Megjegyzés. – Az I. kategóriájú precíziós megközelítés és az APV védelmi szint sértetlenségi veszély az, amikor a GBAS referencia ponthoz viszonyított helyzet jelzésben fel nem fedezett hibák miatt a sértetlenségi veszély nagyobb, mint a hozzájuk kapcsolt védelmi szintek, a két alábbi feltétel esetében:

a) szabvány mérési körülményeknél, ami a 3.6.5.5.1.1 pontban meghatározott; és

b) hibás mérési körülményeknél, ami a 3.6.5.5.1.2 pontban van meghatározva.

3.6.7.1.2.2.2 Annak a GBAS földi al-rendszernek, amely GBAS helymeghatározási szolgáltatást biztosít, a védelmi szint sértetlenségi veszélyének 10^{-9}-nél kevesebbnek kell lenni óránként.

Megjegyzés. – A GBAS helymeghatározási szolgáltatás védelmi szintjénél a védelmi szint sértetlenségi veszély az, amikor a helyzet jelzésben fel nem fedezett hibák miatt a sértetlenségi veszély a referencia ponthoz viszonyítva a vízszintes helyzetben a GBAS helymeghatározási szolgáltatás védelmi szintjénél nagyobb, a két alábbi helyzet esetében:

a) szabvány mérési körülményeknél, ami a 3.6.5.5.2.1 pontban meghatározott; és

b) hibás mérési körülményeknél, ami a 3.6.5.5.2.2 pontban van meghatározva.

3.6.7.1.3 *A szolgáltatás folytonossága*.

3.6.7.1.3.1 *A szolgáltatás folytonossága az I. Kategóriájú precíziós megközelítés és a Megközelítés Függőleges Vezetéssel (APV) számára*. A GBAS földi al-rendszer szolgáltatási folyamatosságának 1 – 3,3 x 10^{-6} –al egyenlőnek, vagy annál nagyobbnak kell lenni bármely 15 másodperc során.

1.Megjegyzés. – A földi al-rendszer szolgáltatási folyamatossága annak a valószínűsége, hogy bármely 15 másodperces időtartam során a VHF adat-sugárzás az adatokat a tűréshatárokon belül továbbítja, a VHF adat-sugárzás térerőssége a meghatározott tartományon belül van, és a védelmi szintek alacsonyabbak a riasztási határértékeknél, kivéve, ha konfiguráció változások történnek űr-szegmens váltás miatt.

3.6.7.1.3.2 *A szolgáltatás folytonossága a helymeghatározási szolgáltatás számára*.

Megjegyzés. – Az olyan GBAS al-rendszerekre, amelyek GBAS helymeghatározási szolgáltatást biztosítanak, lehetnek a tervezett üzemeltetésektől függően kiegészítő folytonossági követelmények is.

3.6.7.2 *Működési követelmények*

3.6.7.2.1 *Általános*

3.6.7.2.1.1 *Adat-sugárzási gyakoriság*.

3.6.7.2.1.1.1 Egy olyan GBAS földi al-rendszernek, mely támogatja az I. Kategóriás precíziós megközelítést, vagy az APV-II-t, 1. Típusú közleményeket kell kiadnia. Egy olyan GBAS földi al-rendszernek, mely nem támogatja az I. Kategóriás precíziós megközelítést, vagy az APV-II-t, 1. Típusú, vagy 101. Típusú közleményeket kell kiadnia. Egy GBAS földi al-rendszernek nem szabad mindkét, az 1. Típusú és a 101. Típusú közleményt kiadnia.

Megjegyzés, - A 101. Típusú közlemény használatával kapcsolatos útmutató anyag a ”D”- Melléklet 7.18 pontjában található.

3.6.7.2.1.1.2 Mindegyik GBAS földi al-rendszernek ki kell sugároznia 2. Típusú közleményeket.

3.6.7.2.1.1.3 Minden GBAS földi al-rendszernek ki kell sugároznia a 4. Típusú üzenetekben lévő Végső Megközelítési szakasz (FAS) blokkokat az összes olyan I. Kategóriás precíziós megközelítésekhez, amit az a GBAS földi al-rendszer támogat. Ha egy GBAS földi al-rendszer támogatja az APV-t, de nem sugároz FAS blokkokat a megfelelő megközelítésekhez, akkor ki kell adnia a 2. Típusú közleményben a kiegészítő adat blokk 1-et.

Megjegyzés. – Az APV eljárásokhoz tartozó FAS blokkokat egy adatbázisban lehet tartani a repülőgép fedélzetén. A kiegészítő adat blokk 1 kisuágárzása lehetővé teszi a fedélzeti vevőnek, hogy kiválassza azt a GBAS földi al-rendszert, amelyik a fedélzeti adatbázisban szereplő megközelítési eljárásokat támogatja. A FAS blokkokat szintén ki lehet adni fedélzeti adatbázis nélküli repülőgép működtetésének támogatásához. Ezek az eljárások eltérő csatorna számokat használnak, ahogy a ”D”- Melléklet 7.7 pontjában megadásra került.

3.6.7.2.1.1.4 Amikor az 5. Típusú közleményeket használják, a földi al-rendszernek az 5. Típusú közleményt a B-76. táblázatban megadott gyakorisággal kell kisugározni.

Megjegyzés. – Amikor a szabvány 5 fokos maszk nem elegendő a műhold láthatóságának megjelölésére, vagy a földi al-rendszer antennáinál vagy a légijárművön egy meghatározott megközelítés során, akkor az 5. Típusú közleményt lehet felhasználni a légijármű részére történő kiegészítő információk sugárzására.

3.6.7.2.1.1.5 *Adat sugárzási gyakoriság*. Azokat az összes típusú közleményeket, amelyek megfelelnek a 3. fejezet 3.7.3.5.4.4.1.2 és 3.7.3.5.4.4.2.2 pontokban leírt térerősség követelményeknek és a B-76. táblázatban megadott minimális gyakoriságnak, a fedésterületen belül, annak minden pontjában biztosítani kell. Az összetett földi al-rendszer teljes antenna rendszer kombinációjából a teljes közlemény sugárzási gyakoriság nem haladhatja meg a B-76. táblázatban megadott maximális gyakoriságot.

Megjegyzés. – Az összetett antenna rendszerek használatára vonatkozó útmutató anyagot a „D”- Melléklet 7.12.4 pontja adja meg.

3.6.7.2.1.2 *Közlemény blokk azonosító*. A közlemény blokk azonosítót /MBI/ vagy a szokásos, vagy az ellenőrzési helyzetbe kell állítani a 3.6.3.4.1 pontban megadott kódolásnak megfelelően.

3.6.7.2.2 *Pszeudó-távolság helyesbítések*

3.6.7.2.2.1 *Közlemény lappangási (várakozási) idő*. A módosított Z-számítás által jelzett idő és a kisugárzott 1. Típusú közlemény, vagy a 101. Típusú közlemény utolsó bitje közötti idő nem haladhatja meg a 0,5 másodpercet.

B-76. táblázat: Földi Bázisú Kiegészítő Rendszer /GBAS/VHF adat-sugárzási gyakoriságok

Közlemény típus	Minimális sugárzási gyakoriság	Maximális sugárzási gyakoriság
1	Az egyes mérési típusokra:	Az egyes mérési típusokra:
	Az összes mérési blokk keretenként egyszer (Megjegyzés)	Az összes mérési blokk időrésenként egyszer
2	20 egymást követő keretenként egyszer	Keretenként egyszer
4	Az összes FAS blokk 20 egymást követő keretenként egyszer	Az összes FAS blokk keretenként egyszer
5	Az összes befogott forrás 20 egymást követő keretenként egyszer	Az összes befogott forrás 5 egymást követő keretenként egyszer

Megjegyzés. – Egy 1. Típusú, vagy 101. Típusú közlemény, vagy két 1. Típusú, vagy 101. Típusú közlemény van összekapcsolva a 3.6.4.2 pontban leírt kiegészítő közlemény jelzés felhasználásával.

3.6.7.2.2.2 *Alacsony-frekvenciás adatok*. Az efemerisz változás időtartamát kivéve a közleményben lévő első távolság-mérési forrást úgy kell sorba rendezni, hogy az efemerisz dekorellációs tényező, az efemerisz CRC és a jelforrás rendelkezésre állási időtartam az egyes műhold helyzetsor rendszerek távolság-mérési forrására legalább 10 másodpercenként egyszer sugárzásra kerüljön. Az efemerisz változás időtartama alatt az első távolság-mérési forrást úgy kell elrendezni, hogy az efemerisz dekorrelációs tényező, az efemerisz CRC és a jelforrás rendelkezésre állási időtartam az egyes műhold helyzetsor rendszerek távolság-mérési forrására legalább 27 másodpercenként egyszer sugárzásra kerüljön. Amikor a műhold helyzetsor rendszer távolság-mérési forrástól egy új efemerisz adat kerül vételre, akkor a földi al-rendszereknek az egyes műholdaktól vett korábbi efemerisz adatokat kell felhasználni addig, amíg az új efemerisz adatokat folyamatosan legalább 2 percen keresztül veszi, de át kell állni az új efemerisz adatokra, mielőtt a 3 perc letelne. Amikor ez az átállás – az egy adott távolság-mérési forrás új efemerisz adatainak felhasználása – megtörténik, akkor a földi al-rendszernek egy új efemerisz CRC-t és egy jelforrás rendelkezésre állási időtartamot kell sugározni a távolság-mérési forrás 1. Típusú, vagy 101. Típusú kisfrekvenciájú információs közleményében a következő három egymást követő keretben minden egyes előfordulásnál. Egy adott távolság-mérési forrásra a földi al-rendszernek folytatnia kell a korábbi efemerisz adatoknak megfelelő adatok sugárzását addig, amíg egy új efemerisz CRC sugárzásra nem kerül az 1. Típusú, vagy a 101. Típusú kisfrekvenciájú adat közleményben (lásd a Megjegyzést). Ha az efemerisz CRC megváltozik és az Adatkibocsátás /IOD/ nem, akkor a földi al-rendszernek a távolság-mérési forrást érvénytelennek kell tekinteni.

Megjegyzés. – Az efemerisz átállás előtti késés elegendő időt hagy a légijármű fedélzeti al-rendszer részére ahhoz, hogy összegyűjtse az új efemerisz adatokat.

3.6.7.2.2.2.1 **Ajánlás**. – *Az efemerisz dekorrelációs tényezőt, az efemerisz CRC-t az egyes műhold helyzetsor rendszerű távolság-mérési forrásokra olyan gyakorisággal kell sugározni, amennyire az csak lehetséges.*

3.6.7.2.2.3 *Sugárzási pszeudo-távolság helyesbítés*. Az egyes sugárzási pszeudo-távolság helyesbítéseket az egyes referencia vevőktől számított megfelelő távolság-meghatározási forrás pszeudo-távolság helyesbítés becslések összekapcsolásával kell meghatározni. Az egyes műholdakra az ebben a kombinációban használt méréseket ugyanazon efemerisz adatokkal kell venni. A helyesbítéseket az egyes műholdakra vonatkozó simított kódú pszeudo-távolság mérésekre kell alapozni a vivőhullám méréseknél egy a 3.6.5.1 pontban leírtaknak megfelelő simító-szűrő alkalmazásával.

3.6.7.2.2.4 *Sugárzási térbeli-jel sértetlenségi paraméterek.* A földi al-rendszernek biztosítania kell a σ_{pr_gnd} és 'B' paramétereket az egyes pszeudo-távolság helyesbítésekre az 1. Típusú közleményekben úgy, hogy a 3.6.7.1.2.2 pontban meghatározott védelmi szint sértetlenségi veszély követelmények kielégítésre kerüljenek. A földi al-rendszernek biztosítania kell a σ_{pr_gnd} és ha szükséges, a 'B' paramétereket az egyes pszeudo-távolság helyesbítésekre a 101. Típusú közleményekben úgy, hogy a 3.6.7.1.2.2 pontban meghatározott védelmi szint sértetlenségi veszély követelmények kielégítésre kerüljenek

Megjegyzés. – A 'B' paraméterek kisugárzása a 101. Típusú közleményekben opcionális (választható). A 101. Típusú közleményben lévő 'B' paraméterekkel kapcsolatos útmutató anyagot a "D"- Melléklet 7.5.11 pontja tartalmazza.

3.6.7.2.2.5 **Ajánlás**. – A referencia vevő méréseket ellenőrizni kell. Hibás méréseket, vagy meghibásodott referencia vevőket nem lehet felhasználni a pszeudo-távolság helyesbítések kiszámításához.

3.6.7.2.2.6 *Az 1. Típusú közlemények, vagy a 101. Típusú közlemények ismételt továbbítása*. Egy adott mérési típushoz és egy adott kereten belül, az összes 1. Típusú, vagy 101. Típusú közlemény sugárzásoknak, vagy az olyan, az összes GBAS sugárzó állomástól érkező összekapcsolt pároknak, melyeknek azonos a GBAS azonosítása, egyforma adattartalommal kell rendelkeznie.

3.6.7.2.2.7 *Adatkibocsátás /IOD/.* A Földi Bázisú Kiegészítő Rendszer /GBAS/ földi al-rendszerének az IOD mezőket az egyes távolság-meghatározási forrás mérési blokkokban úgy kell beállítani, hogy a távolság-meghatározási forrástól vett IOD értéke megfeleljen a pszeudo-távolság helyesbítési számításokhoz használt efemerisz adatoknak.

3.6.7.2.2.8 *A jel hiba modellek alkalmazása*. Az ionoszférikus és a troposzférikus helyesbítéseket nem kell használni a pszeudo-távolság helyesbítések számításához felhasznált pszeudo-távolságoknál.

3.6.7.2.2.9 *Az 1. Típusú közlemények, vagy a 101. Típusú közlemények összekapcsolt párjai*. Amikor az 1. Típusú, vagy a 101. Típusú közlemények összekapcsolt párjai kerülnek továbbításra, akkor:

a) A két közlemény módosított Z-számításának azonosnak kell lenni;

b) A pszeudo-távolság helyesbítések minimális számának minden egyes közleményben egynek kell lenni;

c) Egy adott műholdra vonatkozó mérési blokkot egynél többször nem lehet az összekapcsolt közlemény-párokban továbbítani; és

d) A két közleményt különböző időrésekben kell leadni.

3.6.7.2.2.10 *Módosított Z-számítás felfrissítés*. A módosított Z-számítást egy adott mérési típus 1. Típusú, vagy 101. Típusú közleményében minden egyes keretnél léptetni kell.

3.6.7.2.2.11 *Efemerisz dekorrelációs tényezők.*

3.6.7.2.2.11.1 *I. kategóriájú precíziós megközelítés és Megközelítés Függőleges Vezetéssel (APV).* Azoknál a földi al-rendszereknél, amelyek sugározzák a 2. Típusú közleményben a kiegészítő 1. adatblokkot, a földi al-rendszernek sugároznia kell az efemerisz dekorrelációs tényezőt minden egyes műhold helyzetsor rendszerű távolságmérési forrásra úgy, hogy a földi al-rendszernek a 3.6.7.1.2.1.1 pontban leírt sértetlenségi veszélye kielégítésre kerüljön.

3.6.7.2.2.11.2 *GBAS helymeghatározási szolgáltatás*. Azoknál a földi al-rendszereknél, amelyek biztosítják a GBAS helymeghatározási szolgáltatást, a földi al-rendszernek sugároznia kell az efemerisz dekorrelációs tényezőt minden egyes műhold helyzetsor rendszerű távolságmérési forrásra úgy, hogy a földi al-rendszernek a 3.6.7.1.2.1.2 pontban leírt sértetlenségi veszélye kielégítésre kerüljön.

3.6.7.2.3 *Földi Bázisú Kiegészítő Rendszer /GBAS/ vonatkozású adatok*

3.6.7.2.3.1 *Troposzférikus késési paraméterek*. A földi al-rendszernek a 2. Típusú közleményben sugároznia kell egy törési indexet, egy skála magasságot és egy törési bizonytalanságot úgy, hogy a 3.6.7.1.2.2 pontban meghatározott védelmi szint sértetlenségi veszély kielégítésre kerüljön.

3.6.7.2.3.2 *A Földi folyamatossági/sértetlenségi meghatározás /GCID/ jelzése*. Ha a földi al-rendszer megfelel 3.6.7.1.2.1.1, 3.6.7.1.2.2.1 és a 3.6.7.1.3.1 pont követelményeinek, akkor a GCID-t 1-be kell állítani, más esetekben a beállítása 7 kell, hogy legyen.

3.6.7.2.3.3 *A GBAS referencia antenna fázis középpontja helyzetének pontossága*. Az egyes GBAS referencia vevők referencia antennájának fázis középpont helyzet hibája a GBAS referencia ponthoz viszonyítva 8 cm-nél kevesebb kell, hogy legyen.

3.6.7.2.3.4 **Ajánlás**. – *A GBAS referencia pont felmérési hibája. A GBAS referencia pont felmérési hibája a WGS-84-re vonatkoztatva függőlegesen 0,25 méternél, vízszintesen 1 méternél kevesebb kell, hogy legyen.*

Megjegyzés, - Az ide tartozó útmutató anyagot a "D"- Melléklet 7.16 pontja tartalmazza.

3.6.7.2.3.5 *Ionoszférikus bizonytalanság becslési paraméter*. A földi al-rendszernek egy ionoszférikus késési gradiens paramétert kell sugározni a 2. Típusú közleményben azért, hogy a 3.6.7.1.2.2 pontban meghatározott védelmi szint sértetlenségi veszély követelmény kielégítésre kerüljön.

3.6.7.2.3.6 Azok a földi al-rendszerek, amelyek biztosítják a GBAS helymeghatározási szolgáltatást, a földi al-rendszereiknek sugározni kell az efemerisz-hiba helyzet határ paramétereket, a 2.Típusú közlemény kiegészítő 1. adatblokkját felhasználva.

3.6.7.2.3.7 **Ajánlás.** – *Az összes földi al-rendszernek sugároznia kell az efemerisz-hiba helyzet határ paramétereket, a 2.Típusú közlemény kiegészítő 1. adatblokkját felhasználva.*

3.6.7.2.3.8 Azoknak a földi al-rendszereknek, amelyek sugározzák a kiegészítő 1. adatblokkot a 2. Típusú közleményben, a következő követelményeket kell alkalmazni:

3.6.7.2.3.8.1 *Maximális felhasználási távolság*. A földi al-rendszernek, egy, a GBAS referencia ponttól mért távolságot (D_{max}) kell adni, ami meghatározza azt a „kiterjedést", amelyen belül a földi al-rendszer sértetlenségi veszélye – a 3.6.7.1.2.1 pont szerint – és a védelmi szint sértetlenségi veszély – a 3.6.7.1.2.2 pont szerint – kielégítésre kerülnek.

3.6.7.2.3.8.2 *Efemerisz hibás észlelési paraméterek*. A földi al-rendszernek sugároznia kell az efemerisz hibás észlelési paramétereket az egyes műhold helyzetsor rendszerekre úgy, hogy a 3.6.7.1.2.1 pontnak megfelelő földi al-rendszer sértetlenségi veszély kielégítésre kerüljön.

3.6.7.2.3.8.3 *GBAS helymeghatározási szolgáltatás jelzés*. Amikor a földi al-rendszer nem elégíti ki a 3.6.7.1.2.1.2 pontban és a 3.6.7.1.2.2.2 pontban meghatározott követelményeket, akkor a földi al-rendszernek a referencia pálya adat kiválasztó /RSDS/ paraméter felhasználásával jeleznie kell azt, hogy a GBAS helymeghatározási szolgáltatás nincs biztosítva.

3.6.7.2.3.9 Ha a GRAS szolgáltatási területen belül a VHF adat sugárzást egynél több frekvenciával adják, akkor a GRAS földi al-rendszeren belüli minden egyes GBAS sugárzó állomás ki kell, hogy adja a kiegészítő 1. és 2. adatblokkot.

3.6.7.2.3.9.1 **Ajánlás**. – *A VHF adat sugárzásnak tartalmaznia kell a kiegészítő 2. adatblokk paramétereit a GRAS földi al-rendszeren belüli GBAS sugárzó állomásokhoz közeli és a szomszédos helyek csatorna számainak és helyeinek azonosítására.*

Megjegyzés. – Ez lehetővé teszi a GRAS földi al-rendszeren belül az egyik GBAS sugárzó állomástól a másik GBAS sugárzó állomáshoz az átmenetet.

3.6.7.2.4 *Végső megközelítési szakasz adatok*

3.6.7.2.4.1 *A Végső megközelítési szakasz /FAS/ adat pontok pontossága*. A FAS adat pontok és a GBAS referencia pont közötti relatív felmérési hiba függőlegesen 0,25 méternél kevesebb és vízszintesen 0,40 méternél kevesebb kell, hogy legyen.

3.6.7.2.4.2 *A Műhold Bázisú Kiegészítő Rendszer /SBAS/ FAS adat pontok pontossága*. Az SBAS-el való felhasználásnál a felmérési hiba az összes FAS adat pontra a WGS-84-hez viszonyítva függőlegesen 0,25 méternél, vízszintesen 1 méternél kevesebb kell, hogy legyen.

3.6.7.2.4.3 **Ajánlás**. – A Végső megközelítési szakasz CRC-t az eljárás-tervezés idején kell meghatározni, és ettől az időponttól a későbbiekben a FAS adat blokk egy nélkülözhetetlen részeként meg kell tartani.

3.6.7.2.4.4 **Ajánlás.** – A GBAS-nek meg kell adni azt a lehetőséget, hogy a Végső megközelítési szakasz/Függőleges riasztási határértéket /FASVAL/ és a Végső megközelítési szakasz/Oldalirányú riasztási határértéket /FASLAL/ minden egyes FAS adat-blokkban „1111 1111”-re állítsa azért, hogy jelezze azt, hogy a megközelítést csak oldalirányúvá korlátozza, vagy azért, hogy jelezze azt, hogy a megközelítést nem szabad felhasználni, külön-külön.

3.6.7.2.5 *A távolság-meghatározási jelforrás előre jelzett rendelkezésre állási adata*

Megjegyzés. – A távolság-meghatározási jelforrás rendelkezésre állási adat az I. kategóriára és az APV-re opcionális (választható), és lehet, hogy a jövőben szükséges lesz a lehetséges üzemeltetésekhez.

3.6.7.2.6 *A Globális Navigációs Műhold Rendszer /GNSS/ távolság-meghatározási forrásai sértetlenségének ellenőrzése*. A földi al-rendszernek ellenőrizni kell a műhold jeleket azért, hogy minden olyan helyzetet megállapítson, amely a differenciális jel-feldolgozás helytelen működését fogja eredményezni, a „D”- Melléklet 8.11 pontjában meghatározott követési feltételeknek eleget tevő légijármű fedélzeti vevőkben. A földi al-rendszernek a legerősebb korrelációs csúcsot kell felhasználni az összes, a pszeudo-távolság helyesbítések létrehozására használt vevőben. Az ellenőrző berendezés „idő – a – riasztásig” időtartamának meg kell felelni a 3.6.7.1.2 pontban megadottaknak. Az ellenőrző tevékenységnek a σ_{pr_gnd}–t az „1111 1111” bit-sorozatra kell állítani a műholdra, vagy ki kell zárni a műholdat az 1. Típusú, vagy a 101. Típusú közleményből. A földi al-rendszernek meg kell még határozni azokat a helyzeteket is, amelyek egynél több null-keresztezést eredményeznek az olyan légijármű fedélzeti vevők részére, amelyek a Korai-Késői felismerés funkciót használják, úgy, ahogy az a „D”- Melléklet 8.11 pontjában leírásra került.

3.6.7.3 *Ellenőrzés*

3.6.7.3.1 *Rádiófrekvenciás ellenőrzés*

3.6.7.3.1.1 *A VHF adat-sugárzás ellenőrzése*. Az adat-sugárzás továbbítását ellenőrizni kell. Az adattovábítást 0,5 másodpercen belül be kell szűntetni, ha bármely 3-másodperces időtartamon belül folyamatos ellentét fordul elő a továbbított felhasználói adatok és az ellenőrző rendszerben az ezt a továbbítást megelőzően származtatott és tárolt felhasználói adatok között.

3.6.7.3.1.2 *Az időosztásos többszörös elérés /TDMA/ időrés ellenőrzése*. Annak a veszélye, hogy a földi al-rendszer egy jelet egy hozzárendelés nélküli időrésben sugározzon, és hogy egy időrésen kívüli továbbítást észleljen, - olyant, ami meghaladja azt, amit a 3.6.2.6 pont megenged 1 másodpercen belül - bármely 30-másodperces időtartamban kevesebb kell, hogy legyen 1 x 10^{-7} –nél. Ha a földi al-rendszer időrésen kívüli továbbítást észlel, akkor 0,5 másodpercen belül be kell fejeznie minden adatsugárzási továbbítást.

3.6.7.3.1.3 *VHF adatsugárzás /VDB/ adó teljesítmény ellenőrzés*. Annak a valószínűsége, hogy a vízszintesen vagy elliptikusan polarizált jelek továbbítási teljesítménye bármely 30-másodperces időtartamban a névleges teljesítménytől 3 dB-nél többel 1 másodpercnél hosszabb időre megnövekszik, 2,0 x 10^{-7} -nél kevesebb kell, hogy legyen.

Megjegyzés. – A függőleges összetevő csak a GBAS/E berendezésnél kerül ellenőrzésre.

3.6.7.3.2 *Adat ellenőrzés*

3.6.7.3.2.1 *Sugárzási minőség ellenőrzés*. A földi al-rendszer ellenőrző berendezésének ki kell elégíteni a 3.6.7.1.2.1 pontban megadott idő – a – riasztásig követelményeket. Az ellenőrző berendezés tevékenységének a következők valamelyikének kell lenni:

a) Sugározni az 1. Típusú, vagy a 101. Típusú közleményeket mérési blokkok nélkül; vagy

b) Sugározni az 1. Típusú, vagy a 101. Típusú közleményeket a σ_{pr_gnd} mező beállítással annak jelzésére, hogy a távolság-meghatározási forrás érvénytelen minden távolság-meghatározási forrásra, ami az előzőleg továbbított keretben benne volt; vagy

c) Befejezni az adott sugárzást.

Megjegyzés. – Az a) és a b) ellenőrző tevékenység van előnyben részesítve a c)-vel szemben, ha az adott hiba mód lehetővé tesz egy ilyen választ, azért, mert az a) és a b) tevékenységnek csökkentett térbeli-jel idő – a – riasztásig értéke van.

3.6.7.4 *Földi bázisú távolság-meghatározási források*

Megjegyzés. – A földi bázisú távolság-meghatározási rendszerek várhatóan a 1 559 – 1 610 MHz-es sáv egy részét fogják használni - amelyet az ITU fog kiosztani az RNSS-ARNS szolgáltatás biztosítására – várhatóan ±10 MHz-et megkövetelve a középfrekvencia körül. Mint a GPS és/vagy a GLONASS kiegészítői, ezek is a GNSS részeit fogják képezni, és társított repülési-elektronikai vevőjük lesz. Az interferencia védelmi szintjüknek meg kell egyezni a GNSS vevők interferencia környezetével.

3.6.8 LÉGIJÁRMŰ FEDÉLZETI ALKOTÓELEMEK

3.6.8.1 *Globális Navigációs Műhold Rendszer /GNSS/ vevő.* A Földi Bázisú Kiegészítő Rendszerhez /GBAS/ alkalmas GNSS vevőnek fel kell dolgoznia a GBAS jeleit az ebben a részben meghatározott követelményeknek, valamint a 3.1.3.1 és/vagy a 3.2.3.1 és/vagy a 3.5.8.1 pontok követelményeinek megfelelően.

Megjegyzés. – A GBAS-képességű GNSS vevő megvalósítható a 101. Típusú közlemény, a 2. Típusú közlemény kiegészítő 2. adatblokk, vagy egy 0-s megközelítési teljesítmény kijelölő értékhez kapcsolódó adatfeldolgozás képessége nélkül.

3.6.8.2 *Teljesítmény követelmények*

3.6.8.2.1 *A GBAS légijármű fedélzeti vevő pontossága*

3.6.8.2.1.1 A GPS és a GLONASS hibában a légijármű fedélzeti vevő teljes hozzájárulásának négyzetes középértéke /RMS/ a következő kell, hogy legyen:

$$RMS_{pr\_air}(\theta_n) \le a_0 + a_1 \times e^{-(\theta n/\theta 0)}$$

ahol:

n	= az n-dik távolság-meghatározási forrás;
θ_n	= az n-dik távolság-meghatározási forrás magassági szöge;
a_0, a_1, és θ_0	= ahogy az a B-77. táblázatban a GPS-re és a B-78. táblázatban a GLONASS-ra meghatározásra került.

3.6.8.2.1.2 Az SBAS műholdak hibájában a légijármű fedélzeti vevő teljes hozzájárulásának négyzetes középértékének a 3.5.8.2.1 pontban meghatározottnak kell lenni az egyes meghatározott légijármű pontossági jelöléseknek megfelelően.

Megjegyzés. – A légijármű fedélzeti vevő hozzájárulása nem foglalja magába a repülőgép sárkány többutas terjedése által előidézett mérési hibát.

3.6.8.2.2 *VHF adat-sugárzási vevő teljesítmény*

3.6.8.2.2.1 *VHF adat-sugárzás hangolási tartomány.* A VHF adat-sugárzás vevőjének képesnek kell lenni a 108,000 – 117,975 MHz-es tartományban lévő frekvenciák 25 kHz-es osztással való behangolására.

3.6.8.2.2.2 *VHF adat-sugárzás befogási tartomány.* A VHF adat-sugárzás vevőjének képesnek kell lenni a névleges kijelölt frekvenciától ±418 Hz-el eltérő jelek befogására és befogva tartására.

Megjegyzés. – A GBAS földi al-rendszer frekvencia-stabilitása és a légijármű mozgása miatti legrosszabb helyzetű Doppler-frekvencia változás került a fenti követelményben tükrözésre. Az automatikus frekvencia szabályozás (AFC) dinamika tartományánál is figyelembe kell venni a légijármű fedélzeti VHF adat-sugárzási vevő frekvencia-stabilitási hibahalmazát.

3.6.8.2.2.3 *VHF adat-sugárzási érzékenység tartomány és közlemény meghibásodási arány.* A VHF adat-sugárzási vevőnek el kell érnie azt, hogy a közlemény meghibásodási aránya kevesebb vagy egyenlő legyen, mint egy hibás közlemény 1000 teljes-hosszúságú (222 byte-os) felhasználói adat közleményből, miközben a –87 dBm-től a –1 dBm-ig terjedő tartományban működik, feltéve, hogy az átlagos vett jel teljesítmény változékonysága egy adott időrésben az egymást követő szinkron vezér jelek között nem haladja meg a 40 dB-t. A hibás közlemények magukba foglalják azokat a közleményeket, amelyeket a VHF adat-sugárzási vevő rendszer elveszített, vagy amely nem megy át a Ciklikus Redundancia Ellenőrzésen (CRC) a Vevő oldali hibajavítás /FEC/ alkalmazása után.

B-77. táblázat: Légijármű fedélzeti GPS vevőpontossági követelmény

Légijármű pontossági jelölés	θ_n (fok)	a_0 (méter)	a_1 (méter)	θ_0 (fok)
A	≥5	0,15	0,43	6,9
B	≥5	0,11	0,13	4

B-78. táblázat: Légijármű fedélzeti GLONASS vevőpontossági követelmény

Légijármű pontossági jelölés	θ_n (fok)	a_0 (méter)	a_1 (méter)	θ_0 (fok)
A	≥5	0,39	0,9	5,7
B	≥5	0,105	0,25	5,5

Megjegyzés. – A légijármű fedélzeti VHF adat-sugárzási vevő antenna vízszintesen, vagy függőlegesen polarizált lehet. A sugárzott jelek vízszintesen és függőlegesen polarizált összetevőinek jel erősség különbsége miatt a teljes légijármű fedélzeti beépítési veszteség 15 dB-re van korlátozva a vízszintesen polarizált vevő antennákra és 11 dB-re a függőlegesen polarizált vevő antennákra.

3.6.8.2.2.4 *A VHF adat-sugárzás időrés dekódolása*. A VHF adat-sugárzási vevő meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek a kiválasztott GBAS al-rendszertől jövő összes 1., 2. és 4. Típusú közleményeknél, amelyeknek az Állomás időrés azonosítója /SSID/ megegyezik a kiválasztott GBAS al-rendszeréével. Ezeket a követelményeket ki kell elégíteni más GBAS továbbítások jelenléte esetében mindenképpen és az összes olyan időrésnél, amely a 3.6.8.2.2.5.1 b) pontban jelzett szinteket képviseli.

Megjegyzés. – A más GBAS továbbítások magukba foglalhatják: a) az azonos SSID-vel rendelkező nem 1., 2. és 4. Típusú közleményeket, és b) az eltérő SSID-vel rendelkező közleményeket.

Megjegyzés. – A 101. Típusú közlemények dekódolása. Egy, a 101. Típusú közlemény vételére alkalmas VHF adat-sugárzási vevő meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek a kiválasztott GBAS al-rendszertől jövő összes 101. Típusú közleményeknél. Ezeket a követelményeket ki kell elégíteni más GBAS továbbítások jelenléte esetében mindenképpen és az összes olyan időrésnél, amely a 3.6.8.2.2.5.1 b) pontban jelzett szinteket képviseli.

3.6.8.2.2.5 *Közös csatorna elnyomás*

3.6.8.2.2.5.1 *VHF adat-sugárzás, mint nem-kívánt jelforrás*. A VHF adat-sugárzás vevője meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek egy olyan nem-kívánt közös csatornájú VHF adat-sugárzási jel esetében, amely vagy:

a) Ugyanarra az időrés(ek)re vannak kijelölve és 26 dB-el a megkívánt VHF adat-sugárzási jel teljesítménye alatt, vagy annál lejjebb vannak, vagy

b) Eltérő időrés(ek)re vannak kijelölve, azon teljesítményekre, amelyek 15 dBm-ig terjednek a vevő bemenetén.

3.6.8.2.2.5.2 *VOR, mint nem-kívánt jel*. A VHF adat-sugárzás vevője meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek egy olyan nem-kívánt közös csatornájú VOR jel esetében, ami 26 dB-el alatta van a megkívánt VHF adat-sugárzási jel teljesítményének.

3.6.8.2.2.6 *Szomszédos csatorna elnyomás*

3.6.8.2.2.6.1 *Az első szomszédos 25 kHz-es csatornák (±25 kHz)*. A VHF adat-sugárzás vevője meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek egy olyan sugárzott nem-kívánt jel jelenlétében, amely 25 kHz-el eltolt helyzetű a megkívánt csatorna mindkét oldalán, és ami vagy:

a) 18 dB-el a megkívánt jel teljesítmény felett van, akkor, amikor a nem-kívánt jel egy másik, az ugyanabban az időrésben kijelölt VHF adat-sugárzási jel, vagy

b) A teljesítményében egyenlő és a nem-kívánt jel egy VOR jel.

3.6.8.2.2.6.2 *A második szomszédos 25 kHz-es csatornák (±50 kHz)*. A VHF adat-sugárzás vevője meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek egy olyan sugárzott nem-kívánt jel jelenlétében, amely 50 kHz-el eltolt helyzetű a megkívánt csatorna mindkét oldalán, és ami vagy:

a) 43 dB-el a megkívánt jel teljesítmény felett van, akkor, amikor a nem-kívánt jel egy másik, az ugyanabban az időrés(ek)ben kijelölt VHF adat-sugárzási forrás jele, vagy

b) 34 dB-el a megkívánt jel teljesítmény felett van és a nem-kívánt jel egy VOR jel.

3.6.8.2.2.6.3 *Harmadik és azon túli szomszédos 25 kHz-es csatornák (±75 kHz, vagy több)*. A VHF adat-sugárzás vevője meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek egy olyan sugárzott nem-kívánt jel jelenlétében, amely 75 kHz-el, vagy többel eltolt helyzetű a megkívánt csatorna mindkét oldalán, és ami vagy:

a) 46 dB-el a megkívánt jel teljesítmény felett van, akkor, amikor a nem-kívánt jel egy másik, az ugyanabban az időrés(ek)ben kijelölt VHF adat-sugárzási forrás jele, vagy

b) 46 dB-el a megkívánt jel teljesítmény felett van és a nem-kívánt jel egy VOR jel.

3.6.8.2.2.7 *Csatornán kívüli jelek elnyomása a 108,000 – 117,975 MHz-es sávon belüli forrásokból.* Amikor nincs csatornán belüli VHF adat-sugárzási jel, akkor a VHF adat-sugárzási vevő nem adhat kimenő jelet semmilyen más kijelölhető csatorna nem-kívánt VHF adat-sugárzási csatorna jeléből.

3.6.8.2.2.8 *A 108,000 – 117,975 MHz-es sávon kívüli jel-forrásokból eredő jelek elnyomása*

3.6.8.2.2.8.1 *VHF adat-sugárzási interferencia érzéketlenség*. A VHF adat-sugárzás vevője meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek egy, vagy több olyan jel jelenlétében, amely(ek)nek a frekvenciája és a teljes interferencia szintjei a B-79. táblázatban kerültek meghatározásra.

3.6.8.2.2.8.2 *Érzéketlenítés*. A VHF adat-sugárzás vevője meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek az olyan VHF FM sugárzási jelek jelenlétében, amelyeknek a jel szintjét a B-80. és B-81. táblázatok mutatják be.

3.6.8.2.2.8.3 *VHF adat-sugárzás FM kereszt-modulációs védettség.* A VHF adat-sugárzás vevője meg kell, hogy feleljen a 3.6.8.2.2.3 pontban meghatározott követelményeknek két VHF FM sugárzás jeleinek a két jeltől eredő harmadrendű kereszt-modulációs termék interferenciájának jelenlétében, ha azok szintjei a következőknek felelnek meg:

$$2N_1 + N_2 + 72 \leq 0$$

a VHF FM műsorszóró jelekre a 107,7 – 108,0 MHz-es tartományban, és

$$2N_1 + N_2 + 3\left(24 - 20\log\frac{\Delta f}{0.4}\right) \leq 0$$

a VHF FM műsorszóró jelekre a 107,7 MHz alatt.

ahol a két VHF FM műsorszóró jelek frekvenciája a vevőn belül létrehoz egy két jel-harmadrendű kereszt-modulációs terméket a kívánt VHF adat-sugárzási /VDB/ frekvencián.

Az N_1 és az N_2 a két VHF FM jel szintje (dBm) a VHF adat-sugárzási /VDB/ vevő bemenetén. Egyik szint sem haladhatja meg a 3.6.8.2.2.8.2 pontban lefektetett érzékenység-csökkentő követelményeket.

$\Delta f = 108{,}1 - f_1$, ahol az f_1 annak a VHF FM műsorszóró jelnek az N_1 frekvenciája, amely a 108,1 MHz-hez közelebb van.

Megjegyzés. – Az FM kereszt-modulációs összetettségi követelményeket nem alkalmazzák a 108,1 MHz alatti frekvencián működő VHF adat-sugárzási csatornákra, mivel ezek 108,1 MHz alatti frekvenciák nem az általános kijelölésekre tervezett frekvenciák. Kiegészítő információ került biztosításra a "D"-Melléklet 7.2.1.2 pontjában.

3.6.8.3 *Légijármű fedélzeti működési követelmények*

3.6.8.3.1 *Az adatfelhasználás feltételei*

3.6.8.3.1.1 A vevőnek egy GBAS közleményből az adatokat csak akkor kell felhasználni, ha a közleménynek a Ciklikus Redundancia Ellenőrzése /CRC/ ellenőrzésre került.

3.6.8.3.1.2 A vevőnek csak akkor kell a közlemény adatait felhasználni, ha a közlemény blokk azonosító a „1010 1010" bit mintázatra van állítva.

3.6.8.3.1.3 A vevőnek csak a módosított Z-számítással megegyező távolság-meghatározási jelforrás blokkokat kell felhasználni.

B-79. táblázat: A nem-kívánt jelek maximális szintjei

Frekvencia	A nem-kívánt jel maximális szintje a vevő bemenetén (dBm)
50 kHz-től 88 MHz-ig	–13
88 MHz – 107,900 MHz	(lásd a 3.6.8.2.2.8.2 pontot)
108,000 MHz – 117,975 MHz	kizárva
118,000 MHz	–44
118,025 MHz	–41
118,050 MHz-től 1 660,5 MHz-ig	–13

MEGJEGYZÉSEK. –

1. A fenti frekvenciák által kijelölt egyes szomszédos pontok között az összefüggés lineáris.

2. Ezek az interferencia érzéketlenségi követelmények lehet, hogy nem elegendőek a VHF adat-sugárzási vevők és a VHF összeköttetési rend-szerek összeegyeztethetőség biztosításához, különösen az olyan légi-járműveknél, amelyek a VHF adat-sugárzáshoz függőlegesen polarizált összetevőket használnak. A COM és a NAV frekvencia kiosztás közötti koordináció nélkül, vagy a 112 – 117,975 MHz-es sáv felső végénél egy elválasztó frekvenciasávra vonatkozóan a maximális szintek, amelyek a legalacsonyabb COM VHF csatornaként vannak kijelölve (118,000; 118,00833; 118,01666; 118,025; 118,03333; 118,04166; 118,05) lehet, hogy túllépik a szintet a VHF adat-sugárzási (VDB) vevők bemenetén. Ebben az esetben valamilyen eszköz felszerelésére lesz szükség a COM jeleknek a VDB vevők bemenetén történő csillapítására (például antenna elkülönítés). A végső össze-egyeztethetőség akkor kerülhet majd biztosításra, amikor ez az eszköz a légijárműre felszerelésre került.

B-80. táblázat: A 108,025-től a 111,975 MHz-ig terjedő VHF adat-sugárzási frekvenciákra alkalmazandó érzékenység-csökkentő frekvenciák és teljesítmény követelmények

Frekvencia	A nem-kívánt jel maximális szintje a vevő bemenetén (dBm)
88 MHz ≤ f ≤ 102 MHz	15
104 MHz	10
106 MHz	5
107,9 MHz	– 10

MEGJEGYZÉSEK. –

1. A fenti frekvenciák által kijelölt egyes szomszédos pontok között az összefüggés lineáris.

2. Ez az érzékenység-csökkentő követelmény nem alkalmazandó a 107,7 MHz feletti FM vivőhullámokra és a 108,025 vagy 108,050 MHz-es VHF adat-sugárzási /VDB/ csatornákra. Lásd a "D"- Melléklet 7.2.1.2.2 pontját.

3.6.8.3.1.4 Ha a földi al-rendszer sugározza a D_{max}-ot, akkor a pszeudo-távolság helyesbítéseket csak akkor kell alkalmazni, amikor a GBAS referencia ponttól való távolság a D_{max}-nál kevesebb.

3.6.8.3.1.5 A vevőnek egy adott mérési típusra csak a legutoljára vett helyesbítés sorozatból származó pszeudo-távolság helyesbítéseket kell alkalmazni. Ha a legutoljára vett 1. Típusú, vagy a 101. Típusú közlemény mérési mezőjének száma azt jelzi, hogy nincsenek mérési blokkok, akkor a vevőnek nem kell alkalmazni a GBAS helyesbítéseket arra a mérési típusra.

3.6.8.3.1.6 A vevőnek ki kell zárni a differenciál navigációs megoldásból minden olyan távolság-meghatározási jelforrást, amelynek a σ_{pr_gnd} értéke az „1111 1111" mintázatra van állítva.

B-81. táblázat: A 112,000-tól a 117,975 MHz-ig terjedő VHF adat-sugárzási frekvenciákra alkalmazandó érzékenység-csökkentő frekvenciák és teljesítmény követelmények

Frekvencia	A nem-kívánt jel maximális szintje a vevő bemenetén (dBm)
88 MHz ≤ f ≤ 104 MHz	15
106 MHz	10
107 MHz	5
107,9 MHz	0

MEGJEGYZÉS. – A fenti frekvenciák által kijelölt egyes szomszédos pontok között az összefüggés lineáris.

3.6.8.3.1.7 A vevőnek a differenciál navigációs megoldásban csak akkor kell felhasználnia egy távolság-mérési forrást, ha az 1. Típusú, vagy a 101. Típusú közleményben a módosított Z-számítással jelzett alkalmazhatósági ideje arra a távolság-mérési forrásra 120 másodpercnél nem „öregebb” efemerisz dekorrelációs paramétert tartalmaz.

3.6.8.3.1.8 *Az I. kategóriájú precíziós megközelítést és az APV-t alátámasztó adatok felhasználási feltételei*

3.6.8.3.1.8.1 Az I. kategóriás precíziós megközelítés végső szakaszai, vagy az APV megközelítés során a vevőnek csak azokat a mérési blokkokat kell felhasználni az 1. Típusú, vagy a 101. Típusú közleményekből, amelyeket az utolsó 3,5 másodpercen belül vett.

3.6.8.3.1.8.2 A vevőnek az I. kategóriájú precíziós megközelítés, vagy az APV útirány-vezetésre az egy földi al-rendszertől eredő közlemény adatokat csak akkor kell felhasználni, ha a földi folyamatosság/sértetlenség jelölés (GCID) 1, 2, 3 vagy 4-et jelez a precíziós megközelítés végső szakaszának megkezdését megelőzően.

3.6.8.3.1.8.3 A vevőnek nem szabad figyelembe venni semmilyen változást a GCID-ben a megközelítés végső szakaszai során.

3.6.8.3.1.8.4 A vevőnek nem szabad 4. Típusú közleményben kisugárzott egyedi FAS adat blokkon alapuló függőleges útirány-vezetéses megközelítést biztosítania, ha a megközelítés végső szakaszainak megkezdése előtt vett Végső megközelítési szakasz Függőleges riasztási határérték /FASVAL/ „1111 1111”-re van állítva.

3.6.8.3.1.8.5 A vevőnek nem szabad 4. Típusú közleményben kisugárzott egyedi FAS adat blokkon alapuló alapuló oldalirányú útirány-vezetést biztosítania, ha a megközelítés végső szakaszainak megkezdése előtt vett Végső megközelítési szakasz Oldalirányú riasztási határérték /FASLAL/ „1111 1111”-re van állítva.

3.6.8.3.1.8.6 A megközelítés végső szakaszai során a 4. Típusú közleményben kiadott FASLAL és a FASVAL adatok értékeiben történt változásokat a vevőnek figyelmen kívül kell hagyni.

3.6.8.3.1.8.7 A vevőnek a FAS adatokat csak akkor kell felhasználni, ha ezekre az adatokra a FAS CRC ellenőrzésre került.

3.6.8.3.1.8.8 A vevőnek csak azokat a közleményeket kell felhasználni, amelyekre a GBAS azonosító /ID/ (a közlemény blokk fejrészében) megegyezik annak a 4. Típusú közleménynek a fejrészében lévő GBAS ID-vel, amely a kiválasztott FAS adatokat, vagy azt a 2. Típusú közleményt tartalmazza, mely a kiválasztott RSDS-t foglalja magában.

3.6.8.3.1.8.9 *Végső Megközelítési Szakasz (FAS) adat használata*

3.6.8.3.1.8.9.1 A vevőnek a 4. Típusú közleményeket a FAS meghatározására kell, hogy használja a precíziós megközelítésnél.

3.6.8.3.1.8.9.2 A vevőnek a 4. Típusú közleményeket a FAS meghatározására kell, hogy használja a 20 001 és a 39 999 csatorna számmal társított Megközelítés Függőleges vezetéssel (APV) esetén.

3.6.8.3.1.8.9.3 A vevőnek a légijármű fedélzeti adatbázisában tárolt FAS-t kell használnia a 40 000 és a 99 999 csatorna számmal társított Megközelítés Függőleges vezetéssel (APV) esetén.

3.6.8.3.1.8.10 Amikor a GBAS földi al-rendszer nem sugározza ki a 4. Típusú közleményt és a kiválasztott FAS adat a légijármű fedélzeti adatbázisából rendelkezésre áll, a vevő csak a tervezett GBAS földi al-rendszertől érkező közleményeket használhatja.

3.6.8.3.1.9 *A GBAS helymeghatározási szolgáltatást alátámasztó adatok felhasználási feltételei*

3.6.8.3.1.9.1 A vevőnek csak akkor kell a mérési blokkokat felhasználni, ha azok az utolsó 7,5 másodpercen belül kerültek vételre.

3.6.8.3.1.9.2 A vevőnek csak akkor kell az 1. Típusú közleményekből a mérési blokkokat felhasználni, ha azok az utolsó 5 másodpercen belül kerültek vételre

3.6.8.3.1.9.3 A vevőnek csak akkor kell felhasználni a közlemény adatokat, ha vett egy kiegészítő 1. adatblokkot is magában foglaló 2. Típusú közleményt, és ebben a blokkban a referencia pálya adat kiválasztó /RSDS/ paraméter azt jelzi, hogy a GBAS helymeghatározási szolgáltatás biztosítva van.

3.6.8.3.1.9.4 A vevőnek csak azokat a közleményeket kell felhasználni, amelyekre a GBAS azonosító /ID/ (a közlemény blokk fejrészében) megegyezik annak a 2. Típusú közleménynek a fejrészében lévő GBAS ID-vel, amely a kiválasztott RSDS-t tartalmazza.

3.6.8.3.2 *Sértetlenség*

3.6.8.3.2.1 *Légijármű fedélzeti hibák korlátozása.* A navigációs megoldásban felhasznált egyes műholdakra a vevőnek ki kell számítani egy $\sigma_{receiver}$ –t úgy, hogy a normál eloszlás nulla átlaggal és egy $\sigma_{receiver}$ –rel egyenlő szabvány eltéréssel határolja a vevő hozzájárulását a helyesbített pszeudo-távolság hibához a következők szerint:

$$\int_{y}^{\infty} f(x)\,dx \le Q\left(\frac{y}{\sigma}\right) \text{ az összes } \frac{y}{\sigma} \ge 0 \text{ -ra és}$$

$$\int_{-\infty}^{-y} f(x)\,dx \le Q\left(\frac{y}{\sigma}\right) \text{ az összes } \frac{y}{\sigma} \ge 0 \text{ -ra}$$

ahol:

f(x) = a megmaradó légijármű pszeudo-távolság hiba valószínűség sűrűségi függvénye, és

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_{x}^{\infty} e^{\frac{t^2}{2}} dt$$

3.6.8.3.2.2 *A GBAS sértetlenségi paraméterek felhasználása.* A légijármű fedélzeti rendszer elemeinek ki kell számítania 3.6.5.5 pontban leírt függőleges, oldalirányú és vízszintes védelmi szinteket a GBAS által sugárzott σ_{pr_gnd}, σ_N, h_0, $\sigma_{vert\_iono\_gradient}$ és 'B' paraméterek, valamint a σ_{pr_air} paraméter felhasználásával. Ha a B_{ij} paraméter az „1000 0000" bit mintázatra van állítva, jelezve azt, hogy a mérés nem áll rendelkezésre, akkor a légijármű fedélzeti rendszerének azt kell feltételeznie, hogy a B_{ij} értéke nulla. Az I. kategóriájú precíziós megközelítésre és az APV-re a légijármű fedélzeti rendszer elemeknek ellenőrizni kell azt, hogy a kiszámított függőleges és oldalirányú védelmi szintek kisebbek, mint a 3.6.5.6 pontban meghatározott megfelelő függőleges és oldalirányú riasztási határértékek.

3.6.8.3.3 *A műhold efemerisz adatok felhasználása*

3.6.8.3.3.1 *Adatkibocsátás /IOD/ ellenőrzés.* A vevőnek csak azokat a műholdakat kell felhasználni, amelyeknek a GBAS általi IOD sugárzása az 1. Típusú, vagy a 101. Típusú közleményben megegyezik a vevő által felhasznált, az idő és efemerisz adatokra vonatkozó állandó pályájú műhold helyzetsor rendszer IOD-jával.

3.6.8.3.3.2 *CRC ellenőrzés.* A vevőnek ki kell számítania az efemerisz CRC-t a helyzet megoldásban használt műhold helyzetsor rendszerek hely-meghatározási jelforrásaira. A kiszámított CRC-t érvényesíteni kell az 1. Típusú, vagy a 101. Típusú közleményben lévő efemerisz CRC sugárzással szemben az új sugárzott CRC értékhez viszonyítva 1 másodpercen belül. A vevőnek azonnal meg kell szűntetnie bármely olyan műhold felhasználását, amelyikre a kiszámított és a sugárzott CRC értékek nem megegyezőek.

Megjegyzés. – A VHF adatsugárzási kezdeti adatgyűjtés során a vevő beépíthet a helyzet megoldásba egy műholdat, mielőtt az arra a műholdra sugárzott efemerisz CRC-t venné.

3.6.8.3.3.3 *Efemerisz-hiba helyzet határok.*

3.6.8.3.3.3.1 *Efemerisz-hiba helyzet határok az I. kategóriájú precíziós megközelítésre és a Megközelítés Függőleges vezetésre (APV).* Ha a földi al-rendszer biztosítja a 2. Típusú közleményekben a kiegészítő 1. adatblokkot, akkor a légijármű fedélzeti rendszer elemeinek kell kiszámolni a 3.6.5.8.1 pontban meghatározott efemerisz-hiba helyzet határokat a helyzet megoldásban használatos egyes műhold helyzetsor rendszerű távolságmérési forrásokra a szükségszerűen sugárzott paraméterek vétele utáni 1 másodpercen belül. A légijármű fedélzeti rendszer elemeinek ki kell zárni a helyzet megoldásból azokat a műholdakat, amelyeknek a kiszámított függőleges, vagy oldalirányú efemerisz-hiba helyzet határai (VEBj, vagy LEBj) a 3.6.5.6 pontban meghatározott megfelelő függőleges és oldalirányú riasztási határértékeknél nagyobbak.

Megjegyzés. – A VHF adatsugárzási kezdeti adatgyűjtés során a vevő beépíthet a helyzet megoldásba egy műholdat, mielőtt az arra a műholdra szükségszerűen sugárzott paramétereket az efemerisz-hiba helyzet határok kiszámításához venné.

3.6.8.3.3.3.2 *Efemerisz-hiba helyzet határok a GBAS hely-meghatározási szolgáltatásra.* A légijármű fedélzeti rendszer elemeinek ki kell számítani és a helyzet megoldásban alkalmazni kell a 3.6.5.8.2 pontban meghatározott vízszintes efemerisz-hiba helyzet határt (HEBj) az egyes felhasznált műhold helyzetsor rendszerű távolságmérési forrásokra.

3.6.8.3.4 *Közlemény elvesztés*.

3.6.8.3.4.1 Az I.Kategóriájú precíziós megközelítésnél a vevőnek egy megfelelő riasztást kell adni akkor, ha az utolsó 3,5 másodpercen belül 1. Típusú, vagy 101. Típusú közleményt nem vett.

3.6.8.4.2 A Megközelítések Függőleges vezetésnél (APV) a vevőnek egy megfelelő riasztást kell adni akkor, ha az utolsó 3,5 másodpercen belül 1. Típusú, vagy 101. Típusú közleményt nem vett.

3.6.8.3.4.3 Az 1. Típusú közleményeket használó GBAS hely-meghatározási szolgáltatásnál a vevőnek egy megfelelő riasztást kell adni akkor, ha az utolsó 7,5 másodpercen belül 1. Típusú közleményt nem vett.

3.6.8.3.4.4. A 101. Típusú közleményeket használó GBAS hely-meghatározási szolgáltatásnál a vevőnek egy megfelelő riasztást kell adni akkor, ha az utolsó 7,5 másodpercen belül 101. Típusú közleményt nem vett.

3.6.8.3.5 Pszeudo-távolság mérések a levegőben. Az egyes műholdaktól eredő pszeudo-távolság méréseket simítani kell a vivőhullám mérések felhasználásával és egy olyan simító-szűrővel, amely az inicializálása után 200 másodpercen belül 0,1 méternél kisebb értékkel tér el a szűrőnek, a 3.6.5.1 pontban meghatározott állandósított állapotú átviteléhez viszonyítva, a kód fázis és az integrált vivőhullám fázis közötti 0,01 méter másodpercenkénti eltolódás jelenlétében.

3.7 Interferenciával szembeni ellenállás

3.7.1 TELJESÍTMÉNY CÉLKITŰZÉSEK

1. Megjegyzés. – A kiegészítő rendszer nélküli GPS és GLONASS vevők interferenciával szembeni ellenállása a következő teljesítmény paraméterekre vonatkoztatva kerültek mérésre:

	GPS	*GLONASS*
Követési hiba (1 szigma)	*0,4 m*	*0,8 m*

2. Megjegyzés. – Ez a követési hiba nem foglalja magában sem az olyan jel-terjedés miatti hozzájáruló tényezőket, mint a többutas terjedést, a troposzférikus és ionoszférikus hatásokat, sem az efemerisz és a GPS és GLONASS műholdak óra hibáit.

3. Megjegyzés. – Az SBAS vevőkre az interferenciával szembeni ellenállás a 3.5.8.2.1 és 3.5.8.4.1 pontokban meghatározott paraméterekre vonatkoztatva került mérésre.

4. Megjegyzés. - A GBAS vevőkre az interferenciával szembeni ellenállás a 3.6.7.1.1 és 3.6.8.2.1 pontokban meghatározott paraméterekre vonatkoztatva került mérésre.

5. Megjegyzés. – Az ebben a részben meghatározott jel szintek egy minimális szabvány antenna nyereséget foglalnak magukba az 5 fokos magassági szög felett –4,5 dBic-t. Az elfogadott maximális légijármű antenna nyereség az alacsonyabb hemiszférán –10 dBic. A nem-szabványos antennákra különféle minimális nyereséggel az 5 fokos magassági szög felett a jel – interferencia szintet szabályozni lehet addig, amíg a relatív interferencia – jel szint fenntartható lesz .

6. Megjegyzés. – Az interferencia környezetekben a kielégítendő teljesítmény követelmények a következőkben vannak a repülés különböző szakaszaira meghatározva.

3.7.2 FOLYTONOS HULLÁM (CW) INTERFERENCIA

3.7.2.1 *GPS és SBAS vevők*

3.7.2.1.1 A precíziós megközelítési szakaszban használt, vagy a légijárműveken a fedélzeten a műholdas összeköttetésre használt GPS és SBAS vevőknek a Folytonos hullámú /CW/ zavaró jelek jelenlétében ki kell elégíteniük azt a teljesítmény célt, hogy az antenna kimenetén az interferencia küszöb egyenlő legyen a B-82. táblázatban meghatározott értékekkel és a B-15. ábrán bemutatottakkal és egy -164,5 dBW megkívánt jelszinttel az antenna kimenetén.

3.7.2.1.2 A nem-precíziós megközelítéseknél használt GPS és SBAS vevőknek a B-82. táblázatban meghatározottaknál 3 dB-el kisebb interferencia küszöbű teljesítmény céloknak kell megfelelni. A közelkörzeti területeken és az útvonal-repülés állandósult helyzetű navigációjú üzemeltetéseknél, valamint az állandósult helyzetű navigációt megelőző helyzetben, és a GPS és SBAS jelek lekérdezésének megkezdésekor, az interferencia küszöbnek 6 dB-el kevesebb-nek kell lenni a B-82. táblázatban meghatározott értékeknél.

3.7.2.2 *GLONASS vevők*

3.7.2.2.1 A precíziós megközelítési szakaszban használt, vagy a légijárműveken a fedélzeten a műholdas összeköttetésre használt GLONASS vevőknek a Folytonos hullámú /CW/ zavaró jelek jelenlétében ki kell elégíteniük azt a teljesítmény célt, hogy az antenna kimenetén az interferencia küszöb egyenlő legyen a B-83. táblázatban meghatározott értékekkel és a B-16. ábrán bemutatottakkal és egy -165,5 dBW megkívánt jelszinttel az antenna kimenetén.

3.7.2.2.2 A nem-precíziós megközelítéseknél használt GLONASS vevőknek a B-83. táblázatban meghatározottaknál 3 dB-el kisebb interferencia küszöbű teljesítmény céloknak kell megfelelni. A közelkörzeti területeken és az útvonal-repülés állandósult helyzetű navigációjú üzemeltetéseknél, valamint az állandósult helyzetű navigációt megelőző helyzetben, és a GLONASS jelek lekérdezésének megkezdésekor, az interferencia küszöbnek 6 dB-el kevesebbnek kell lenni a B-83. táblázatban meghatározott értékeknél.

B-82. táblázat: Folytonos hullámú /CW/ interferencia küszöbök a GPS és SBAS vevőkre

Az interferencia jel f_i frekvencia tartománya	Interferencia küszöbök a repülés precíziós megközelítési szakaszában használt vevőkre
f_i ≤ 1315 MHz	–4,5 dBW
1315 MHz < f_i ≤ 1525 MHz	Lineárisan csökkenő a –4,5 dBW-től a –42 dBW-ig
1525 MHz < f_i ≤ 1565,42 MHz	Lineárisan csökkenő a –42 dBW-től a –150,5 dBW-ig
1565,42 MHz < f_i ≤ 1585,42 MHz	–150,5 dBW
1585,42 MHz < f_i ≤ 1610 MHz	Lineárisan növekvő a –150,5 dBW-től a –60 dBW-ig
1610 MHz < f_i ≤ 1618 MHz	Lineárisan növekvő a –60 dBW-től a –42 dBW-ig*
1618 MHz < f_i ≤ 2000 MHz	Lineárisan növekvő a –42 dBW-től a –8,5 dBW-ig*
1610 MHz < f_i ≤ 1626,5 MHz	Lineárisan növekvő a –60 dBW-től a –22 dBW-ig**
1626,5 MHz < f_i ≤ 2000 MHz	Lineárisan növekvő a –22 dBW-től a –8,5 dBW-ig**
f_i > 2000 MHz	–8,5 dBW

* Olyan légijármű fedélzeti berendezésekre alkalmazandó, ahol nincs fedélzeti műholdas összeköttetés.
** Olyan légijármű fedélzeti berendezésekre alkalmazandó, ahol van fedélzeti műholdas összeköttetés.

B-83. táblázat: Interferencia küszöbök a GLONASS vevőkre

Az interferencia jel f_i frekvencia tartománya	Interferencia küszöbök a repülés precíziós megközelítési szakaszában használt vevőkre
f_i ≤ 1315 MHz	–4,5 dBW
1315 MHz < f_i ≤ 1562,15625 MHz	Lineárisan csökkenő a –4,5 dBW-től a –42 dBW-ig
1562,15625 MHz < f_i ≤ 1583,6525 MHz	Lineárisan csökkenő a –42 dBW-től a –80 dBW-ig
1583,6525 MHz < f_i ≤ 1592,9525 MHz	Lineárisan csökkenő a –80 dBW-től a –149 dBW-ig
1592,9525 MHz < f_i ≤ 1609,36 MHz	–149 dBW
1609,36 MHz < f_i ≤ 1613,65625 MHz	Lineárisan növekvő a –149 dBW-től a –80 dBW-ig
1613,65625 MHz < f_i ≤ 1635,15625 MHz	Lineárisan növekvő a –80 dBW-től a –42 dBW-ig*
1613,65625 MHz < f_i ≤ 1626,15625 MHz	Lineárisan növekvő a –80 dBW-től a –22 dBW-ig**
1635,1525 MHz < f_i ≤ 2000 MHz	Lineárisan növekvő a –42 dBW-től a –8,5 dBW-ig*
1626,15625 MHz < f_i ≤ 2000 MHz	Lineárisan növekvő a –22 dBW-től a –8,5 dBW-ig**
f_i > 2000 MHz	–8,5 dBW

* Olyan légijármű fedélzeti berendezésekre alkalmazandó, ahol nincs fedélzeti műholdas összeköttetés.

** Olyan légijármű fedélzeti berendezésekre alkalmazandó, ahol van fedélzeti műholdas összeköttetés.

3.7.3 SÁV-HATÁROLT ZAJ-TÍPUSÚ INTERFERENCIA

3.7.3.1 *GPS és SBAS vevők*

3.7.3.1.1 Miután az állandósult helyzetű navigációs üzemeltetés létrejött, azoknak a GPS és SBAS vevőknek, amelyek a repülés precíziós megközelítési szakaszaiban használatosak, vagy a légijárműveken fedélzeti műholdas összeköttetéseket használnak, ki kell elégíteniük a teljesítmény célt, ha az 1 575,42 MHz ±Bwi/2 frekvencia tartományban zaj-típusú interferencia jelek vannak, és a teljesítmény szintek az antenna kimenetén megegyeznek a B-84. táblázatban és a B-17. ábrán meghatározott interferencia küszöbökkel és a megkívánt jel szint -164,5 dBW az antenna kimenetén.

Megjegyzés. – A Bw_i az interferencia jel egyenértékű zaj sávszélessége.

3.7.3.1.2 A nem-precíziós megközelítéseknél használt GPS és SBAS vevőknek meg kell felelniük a teljesítmény céljaiknak az interferencia küszöbükkel a B-84. táblázatban meghatározott értékeknél 3 dB-el kisebb sáv- határolt zaj kimeneti jelek esetében. A közelkörzeti területeken és az útvonal-repülés állandósult helyzetű navigációjú üzemeltetéseknél, valamint az állandósult helyzetű navigációt megelőző helyzetben, és a GPS és SBAS jelek lekérdezésének megkezdésekor, az interferencia küszöbnek a sáv-határolt zaj-típusú interferenciára 6 dB-el kevesebbnek kell lenni a B-84. táblázatban meghatározott értékeknél.

3.7.3.2 *GLONASS vevők*

3.7.3.2.1 Miután az állandósult helyzetű navigációs üzemeltetés létrejött, azoknak a GLONASS vevőknek, amelyek a repülés precíziós megközelítési szakaszaiban használatosak, vagy a légijárműveken fedélzeti műholdas összeköttetéseket használnak, ki kell elégíteniük a teljesítmény célt, miközben zaj-típusú interferencia jeleket vesznek az $f_k \pm Bw_i/2$ frekvencia sávban az antenna kimenetén olyan teljesítmény szintekkel, amelyeknél az interferencia küszöbök egyenlőek a B-85. táblázatban meghatározottakkal, és -165,5 dBW megkívánt jelszinttel az antenna kimenetén.

Megjegyzés. - Az f_k a GLONASS csatorna középfrekvenciája f_k = 1602 MHz + k x 0,6525 MHz-nél és a k = -7-től + 13-ig értékű, ahogy az a B-16. táblázatban meghatározásra került és a Bw_i az interferencia jel egyenértékű zaj sávszélessége.

3.7.3.2.2 A nem-precíziós megközelítéseknél használt GLONASS vevőknek a B-84. táblázatban meghatározottaknál 3 dB-el kisebb interferencia küszöbű teljesítmény céloknak kell a sáv-határolt zaj-típusú interferenciára megfelelni. A közelkörzeti területeken és az útvonal-repülés állandósult helyzetű navigációjú üzemeltetéseknél, valamint az állandósult helyzetű navigációt megelőző helyzetben, és a GLONASS jelek lekérdezésének megkezdésekor, az interferencia küszöböknek a sáv-határolt zaj-típusú jelekre 6 dB-el kevesebbnek kell lenni a B-85. táblázatban meghatározott értékeknél.

Megjegyzés. – A repülés megközelítési szakaszára elfogadott az, hogy a vevő követési módban működik és nem fog be új műholdakat.

3.7.3.3. *Pulzáló interferencia*. Miután az állandósult helyzetű navigációjú üzemeltetés létrejött, a vevőnek ki kell elégítenie a teljesítmény célját, miközben a B-86. táblázatban meghatározott karakterisztikájú pulzáló jeleket vesz ott, ahol az interferencia küszöb az antenna bemenetre van meghatározva.

3.7.3.4 Az SBAS és GBAS vevőknek nem szabad kiadni félrevezető információt interferencia jelenlétében, beleértve a 3.7 pontban meghatározott feletti frekvencia szinteket is.

Megjegyzés. – Az erre a követelményre vonatkozó útmutató anyag a "D"- Melléklet 10.6 pontjában került megadásra.

3.8 Globális Navigációs Műhold Rendszer /GNSS/ légijármű fedélzeti műhold vevő antenna

3.8.1 3.8.1 *Antenna fedés*. A GNSS antenna meg kell, hogy feleljen a GNSS műhold jelek vételére vonatkozó teljesítmény követelményeknek, oldalszögben 0-tól 360 fokig és magassági szögben 0-tól 90 fokig a szintbeli repülésben lévő légijármű vízszintes síkjához viszonyítva.

3.8.2 *Antenna nyereség*. A minimális antenna nyereség nem lehet kevesebb annál, mint ami a B-87. táblázatban megadásra került a horizont feletti meghatározott magassági szögre. A maximális antenna nyereség nem haladhatja meg a +7 dBic-t az 5 fok feletti magassági szögekre.

3.8.3 *Polarizáció*. A GNSS antenna polarizációjának jobbra körkörösnek kell lenni (az óramutató járásával megegyező irányú a terjedés irányára vonatkozóan).

3.9 Ciklikus Redundancia Ellenőrzés /CRC/

Az egyes CRC-ket két bináris kifejezés Modulo-2 osztásának R(x) maradékaként kell kiszámítani, a következők szerint:

$$\left\{\frac{[x^k M(x)]}{G(x)}\right\}_{\mathrm{mod}\,2} = Q(x) + \frac{R(x)}{G(x)}$$

ahol:

k	=	Az adott CRC bitjeinek száma;
M(x)	=	Az az információs mező, amely egy meghatározott polinommal képviselt CRC-vel védendő adat elemekből áll;
G(x)	=	Az adott CRC meghatározott generáló polinomja;
Q(x)	=	Az osztás hányadosa; és
R(x)	=	Az osztás maradéka, magába foglalja a CRC-t:

$$R(x) = \sum_{i=1}^{k} r_i x^{k-i} = r_1 x^{k-1} + r_2 x^{k-2} + \ldots + r_k x^0$$

B-84. táblázat: Interferencia küszöbök a precíziós megközelítéseknél használt GPS és SBAS vevők sáv-határolt zajszerű interferenciájára

Interferencia sávszélesség	Interferencia küszöb
0 Hz < Bw_i ≤ 700 Hz	–150,5 dBW
700 Hz < Bw_i ≤ 10 kHz	–150,5 + 6 $\log_{10}$ (BW/700) dBW
10 kHz < Bw_i ≤ 100 kHz	–143,3 + 3 $\log_{10}$ (BW/10000) dBW
100 kHz < Bw_i ≤ 1 MHz	–140,5 dBW
1 MHz < Bw_i ≤ 20 MHz	Lineárisan növekvő a –140,5-től a –127,5 dBW-ig*
20 MHz < Bw_i ≤ 30 MHz	Lineárisan növekvő a –127,5-től a –121,1 dBW-ig*
30 MHz < Bw_i ≤ 40 MHz	Lineárisan növekvő a –121,1-től a –119,5 dBW-ig*
40 MHz < Bw_i	–119,5 dBW*

* Az interferencia küszöb nem haladhatja meg a –140,5 dBW/MHz –t az 1 575,42 ± 10 MHz-es frekvencia tartományban.

B-85. táblázat: Interferencia küszöbök a precíziós megközelítéseknél használt GLONASS vevők sáv-határolt zajszerű interferenciájára

Interferencia sávszélesség	Interferencia küszöb
0 Hz < Bw_i ≤ 1 kHz	–149 dBW
1 kHz < Bw_i ≤ 10 kHz	Lineárisan növekvő a –149-től a –143 dBW-ig
10 kHz < Bw_i ≤ 0,5 MHz	–143 dBW
0,5 MHz < Bw_i ≤ 10 MHz	Lineárisan növekvő a –143-től a –130 dBW-ig
10 MHz < Bw_i	–130 dBW

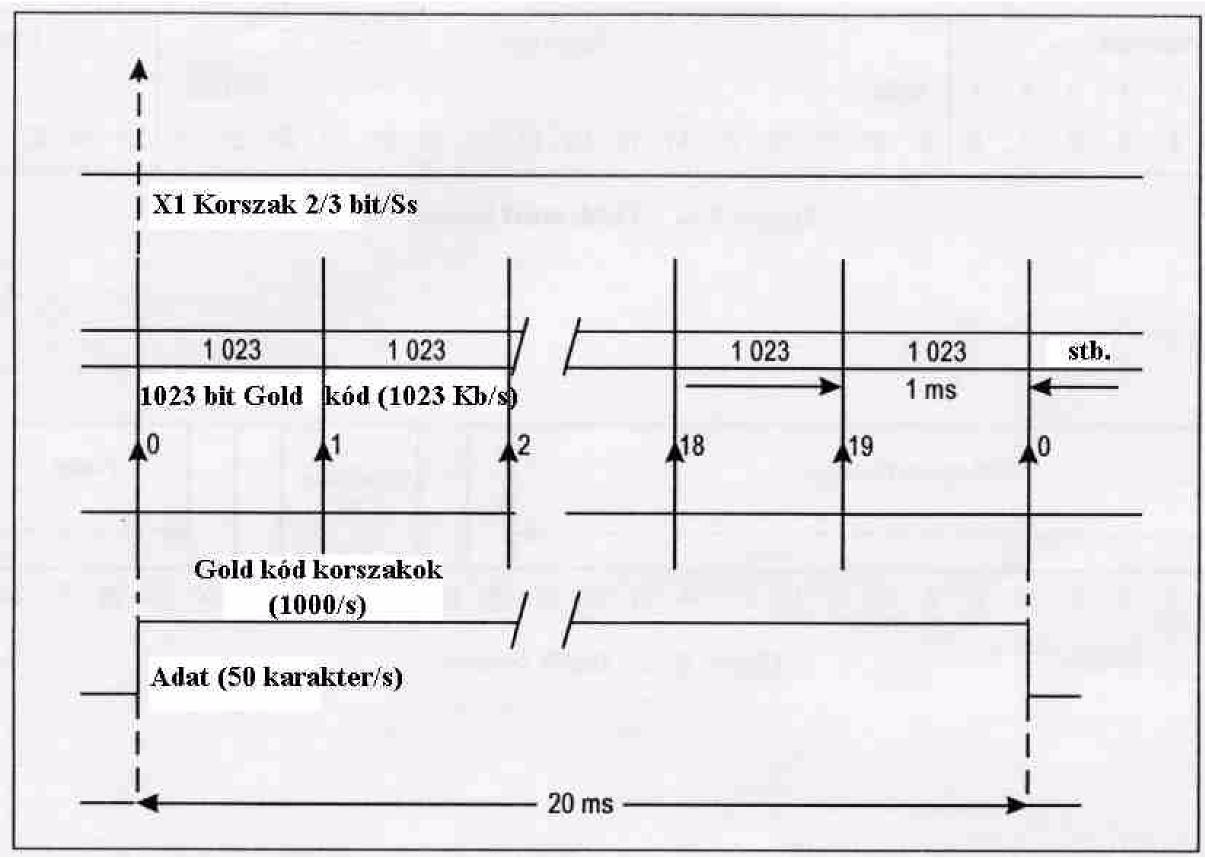
B-86. táblázat: Interferencia küszöbök impulzusos interferenciára

	GPS és SBAS	GLONASS
Frekvencia tartomány	1 575,42 MHz ± 10 MHz	1 592,9525 MHz-től az 1 609,36 MHz-ig
Interferencia küszöb (Impulzus csúcs teljesítmény)	–10 dBW	–10 dBW
Impulzus szélesség	≤ 125 μs, ≤ 1 ms*	≤ 1 ms
Impulzus kitöltési tényező	≤ 10 %	≤ 10 %

B-87. táblázat: Minimális antenna nyereség – GPS/SBAS és GLONASS

Magassági szög, fok	Minimális nyereség, dBic
0	–7,5
5	–4,5
10	–3
15-től 90-ig	–2

A B-Függelék ábrái

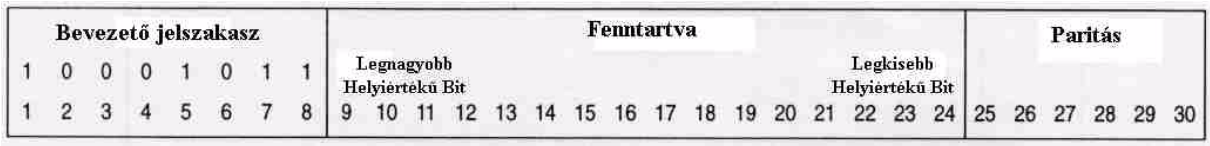


B-1. ábra: Torzított (durva) hozzáférési /C/A/ kód időzítési összefüggések

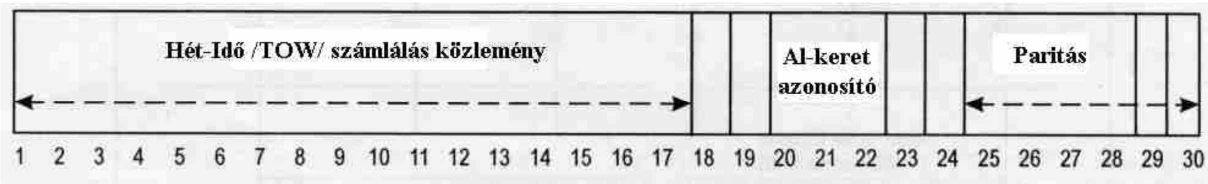
1. Al-keret	Távolság-mérés/TLM/	Átadás/HOW/	GPS hét szám, Navigációs műhold /*SV*/ pontosság és működési állapot
2. Al-keret	TLM	HOW	Efemerisz paraméterek
3. Al-keret	TLM	HOW	Efemerisz paraméterek
4. Al-keret (25 oldal)	TLM	HOW	Naptár adatok és működési állapot a 25 – 32 műholdakra, különleges körülmények, műhold konfiguráció, jelzések, ionoszféra és UTC
5. Al-keret (25 oldal)	TLM	HOW	Naptár adatok és működési állapot az 1 – 24 műholdakra és naptár referencia idő, és GPS hét szám

A fordító megjegyzése:
Az *'SV'* rövidítés a *'Space Vehicles'* rövidítése, azaz űrhajó, kozmikus űrjármű; mivel itt ez a 'navigációs műholdakra' vonatkozik, és a magyar nyelvben az űrhajó és a kozmikus űrjármű már más jelentésben tudatosult, ezért *navigációs műhold*-ként van fordítva.

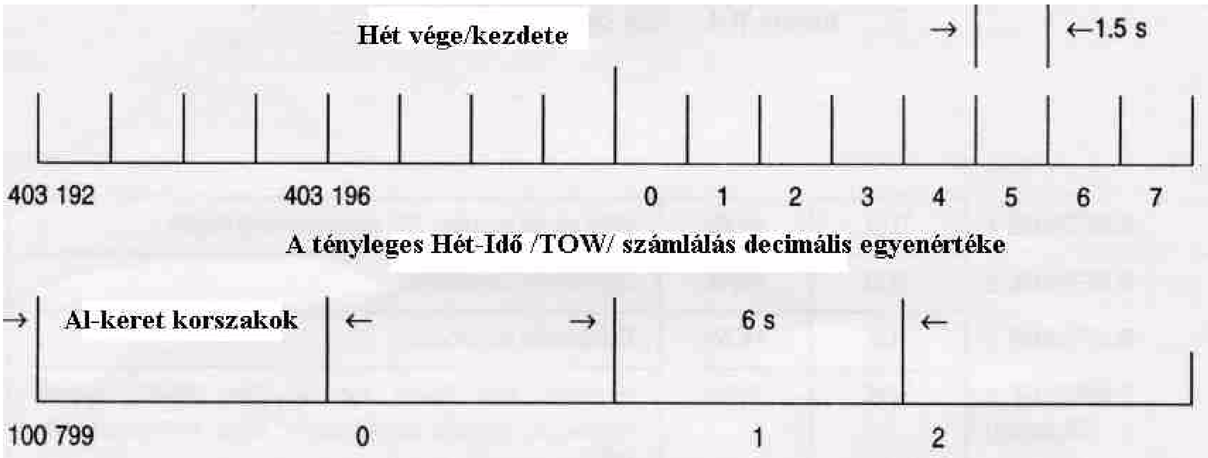
B-2. ábra: Keret szerkezet



B-3. ábra: Távolságmérés /TLM/ szó formátum



B-4. ábra: Átadás /HOW/ formátum



Az Átadás /HOW/ közlemény Hét – Idő /TOW/ számlálás decimális egyenértéke

B-5. ábra: Az Átadás /HOW/ Idő vonal összefüggése

Megjegyzések:

1. A gyors földi befogás elősegítésére, az egyes al-keretek átadása /HOW/ magába foglal egy megcsonkított Hét – Idő /TOW/ számlálást.
2. Az Átadás /HOW/ a második szó az egyes al-keretekben.
3. Az Átadás /HOW/ közlemény Hét – Idő /TOW/ számlálása a tényleges TOW számlálás 17 Legnagyobb Helyértékű Bitjéből áll a következő al-keret kezdeténél.
4. Az Átadás /HOW/ közlemény Hét – Idő /TOW/ számlálásából a tényleges számlálásra való átalakításhoz a következő al-keret elejénél néggyel kell szorozni.
5. Az első al-keret szinkronban kezdődik az egyes korszakok vége/elejével.

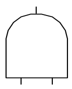
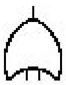
"A" MELLÉKLET: A SZOLGÁLTATÁSI CÉLOK TELJESSÉGÉNEK (INTEGRITÁS) ÉS FOLYAMATOSSÁGÁNAK MEGHATÁROZÁSA A KOCKÁZATI FA MÓDSZER FELHASZNÁLÁSÁVAL

1. A kockázati fa módszer egy grafikai mód az egy meghatározott meghibásodás állapot és az ezen állapothoz vezető okok, vagy meghibásodások közötti logikai kapcsolat kifejezéséhez. Ez a légiközlekedési iparban alkalmazásban lévő hiba fa elemzés alkalmazása.

1.1 A módszerben egy logikai szimbólum sorozat kerül alkalmazásra a különféle meghibásodások okai közötti kapcsolat ábrázolására. Ebben az útmutató anyagban a következő szimbólumok használatosak:

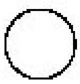


Az "ÉS" kapu azt a logikai műveletet írja le, amely által az összes bemenő eset együtt étezése szükségszerű, hogy létrehozza a kimenő esetet.



A "VAGY" kapu egy olyan helyzetet határoz meg, amely által a kimeneti eset akkor fog fennállni, amikor egy vagy több bemenő eset fennáll.

A téglalap egy olyan esetet azonosít, ami a bemenő logikai kapun keresztüljutó hibák, vagy meghibásodások kombinációjából származik.



A kör egy olyan elsődleges meghibásodási esetet ír le, ami nem igényel további kifejtést. Az így azonosított tételek meghibásodási módja és gyakorisága tapasztalati adatokból kerül levezetésre.

1.2 A módszer az esetek egymás után következésének és kombinációjának azt a vizuális ábrázolását adja meg, ami a legnagyobb meghibásodási eseményhez vezet. A módszert fel lehet használni a legnagyobb meghibásodási esemény bekövetkezése valószínűségének meghatározására, feltéve, hogy az egyedi események valószínűsége ismert, vagy megbecsülhető. Egy egyszerű hiba esetén a fa-valószínűségeket közvetlenül lehet kiszámítani, de gondosan kell eljárni akkor, amikor az elsődleges meghibásodási esemény nem független, azaz a meghibásodási események egynél több vonalvezetéssel közösek.

1.3 Ebben az útmutató anyagban az előforduló legmagasabb szintű esemény elfogadható valószínűsége a kockázat elosztásával kerül meghatározásra, és a hiba-fa a kockázatnak az integritási és a szolgáltatás folyamatossági kockázatba történő további felosztására használatos. Ennek megfelelően inkább a "kockázati fa" kifejezést használjuk a "hiba-fa" kifejezés helyett.

2. Az általános kockázati fa a légijárművek leszállási műveleteire az A-1. számú ábrán került megadásra. Ennél a fánál a legnagyobb eseménynek a légijárműnek az egy nem-légijármű fedélzeti eredetű útirány-vezetési rendszer meghibásodása miatti elvesztését vettük. Ennek az eseménynek az

okai vagy az elsődleges nem-légijármű fedélzeti eredetű útirány-vezetési berendezés integritási meghibásodása, vagy a nem-légijármű fedélzeti eredetű útirány-vezetési rendszer szolgáltatási folyamatosságának (COS) hibája (azaz mindkettő, az az elsődleges rendszer és az a bármilyen másodlagos rendszer, ami a félbeszakított megközelítés / megszakított megközelítés alátámasztására használatos). Az elsődleges nem-légijármű fedélzeti útirány-vezetési rendszernél több elem került figyelembevételre az 1-től az N-ig terjedően, például az oldalszög adó, a magassági szög adó és a DME / P az MLS esetében. A másodlagos útirány-vezetési rendszer egy alternatív nem-légijármű fedélzeti rendszer lehet, vagy bizonyos esetekben egy légijármű fedélzeti navigációs rendszer, mint például egy inerciális referencia rendszer.

2.1 A következő valószínűségeket lehet meghatározni:

P_a = A légijármű elvesztésének valószínűsége a nem-légijármű fedélzeti útirány-vezetési rendszer meghibásodása miatt.

P_b = A légijármű elvesztésének valószínűsége az elsődleges útirány-vezetés integritási meghibásodása miatt.

P_c = A légijármű elvesztésének valószínűsége a szolgáltatási folyamatosság (COS) meghibásodása miatt.

P_x = Annak a valószínűsége, hogy a légijárművezető nem képes sikeresen észlelni és közbelépni egy elsődleges útirányvezetési integritás meghibásodást követően. A kockázat csökkentő tényező csak azoknál az eseteknél lényeges, ahol az útirány-vezetési rendszer integritási meghibásodását a légijármű vezetője észlelni tudja, azaz egy I. Kategóriájú ILS megközelítésnél az elhatározási magasságon.

P_p = Az elsődleges útirány-vezetési szolgáltatási folyamatosság (COS) meghibásodásának valószínűsége.

P_d = A légijármű elvesztésének valószínűsége egy félbeszakított megközelítés / megszakított megközelítés végrehajtása során.

P_i = Az elsődleges útirány-vezetés integritási meghibásodásának valószínűsége.

P_{iN} = Az N Navigációs berendezés-egység integritási hibájának valószínűsége.

P_{pN} = Az N Navigációs berendezés-egység szolgáltatási folyamatossági (COS) meghibásodásának valószínűsége.

P_s = A légijármű elvesztésének valószínűsége egy félbeszakított megközelítés / megszakított megközelítés végrehajtása során, a másodlagos útirány-vezetéssel.

P_{s1} = A másodlagos útirány-vezetési szolgáltatási folyamatosság (COS) meghibásodásának valószínűsége.

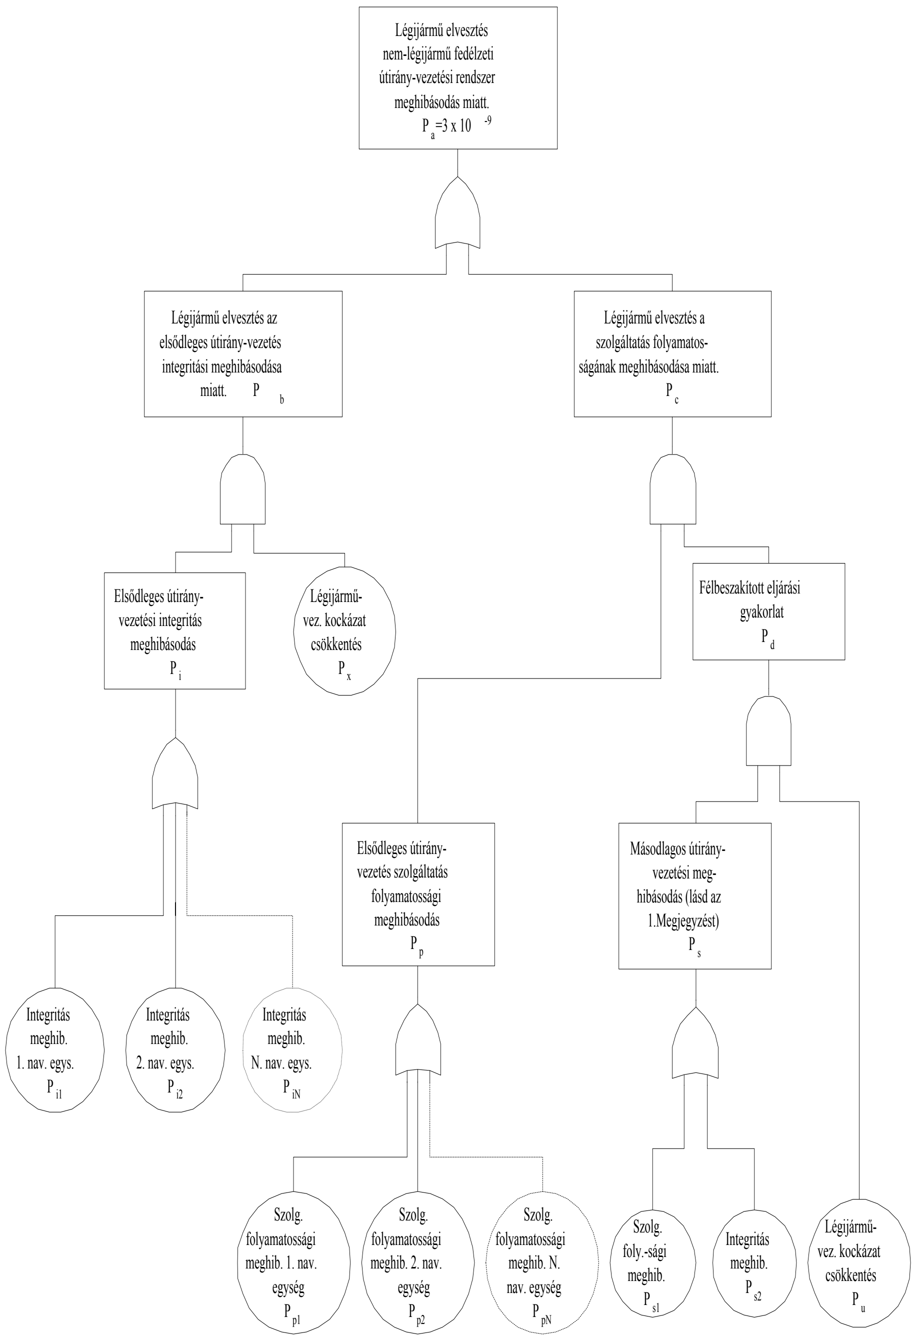
P_{s2} = A másodlagos útirány-vezetés integritási meghibásodásának valószínűsége.

P_u = Annak a valószínűsége, hogy a légijárművezető nem képes sikeresen közbelépni egy elsődleges útirány-vezetési szolgáltatás folyamatossági meghibásodást követően és nem áll rendelkezésre másodlagos útirány-vezetés.

Ahol:
$P_a = P_b + P_c$
$P_b = P_i\, P_x$
$P_i = P_{i1} + P_{i2} + ...P_{iN}$
$P_c = P_p\, P_d$
$P_p = P_{p1} + P_{p2} + ...P_{pN}$
$P_d = P_s\, P_u$
$P_s = P_{s1} + P_{s2}$

2.2 A legnagyobb esemény, P_a, elfogadható valószínűségét az összes kockázati tényezőnek a megközelítési és leszállási üzemeltetéseknél a balesetek különféle osztályaira történő felosztásával lehet meghatározni. Ezt a módszert alkalmazva a P_a elfogadható értéke 3×10^{-9}-ként került meghatározásra. Ez azzal a legkisebb valószínűséggel egyezik meg, amit az egyes földi navigációs egységekre ki lehet jelölni, ami 1×10^{-9} (szabályszerűen egyenlően elosztva az integritás és a szolgáltatási folyamatosság között).

2.3 A fenti kockázat elemzés alapfeltételként elfogadja azt, hogy nincsenek berendezés tervezési hibák.

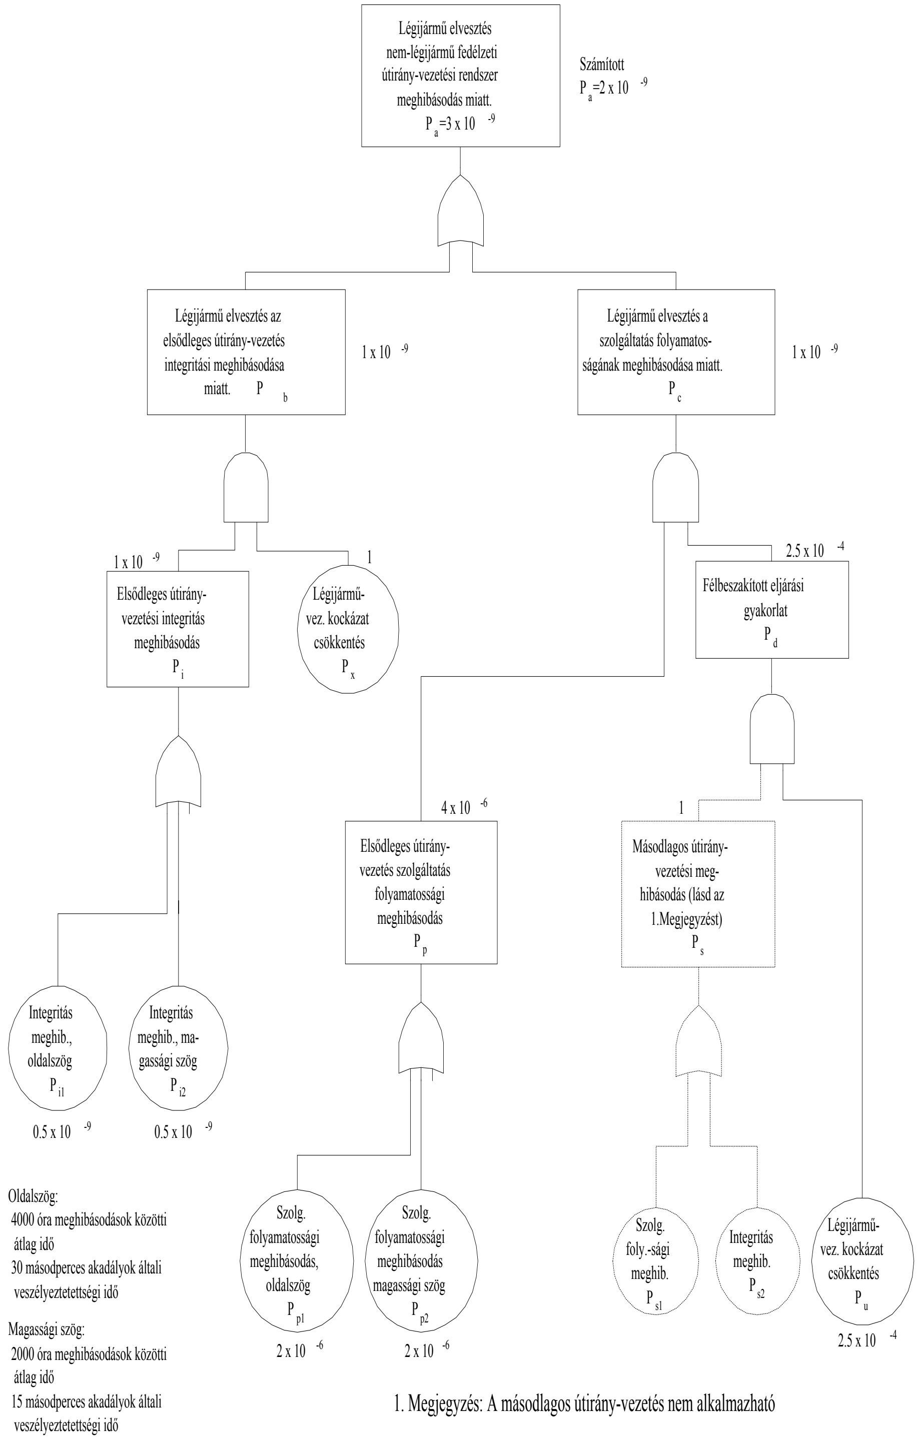


$$P_{pn} = \frac{\text{akadályok általi veszélyeztetettségi idő}}{\text{meghibásodások közötti átlagos idő}}$$

1. Megjegyzés: A másodlagos útirány-vezetés lehet légijármű fedélzeti vagy nem-légijármű fedélzeti útirány-vezetési rendszer.

A-1. ábra: Általános kockázati fa

3. *Példa a kockázati fának az MLS III. kategóriájú alap üzemeltetésekre (A-2. ábra) történő alkalmazására*.



A-2. ábra: Az MLS III. kategóriájú leszállás kockázati fája

$P_{i1} = P_{i2} = 0{,}5 \times 10^{-9}$

$P_{p1} = P_{p2} = 2 \times 10^{-6}$

Megjegyzés. - Ezek a számok a "G" Melléklet G-15. táblázata 4. szintjéből származnak, és 30 és 15 másodperces akadályok általi veszélyeztetettségi időt, valamint 4 000 és 2 000 órás meghibásodások közötti átlagos időt tételeznek fel külön-külön az oldalszög és a magassági szög adó egységekre.

$P_s = 1{,}0$

Megjegyzés. - Mivel nincs másodlagos útirány-vezetést felhasználó vezetett félbeszakított / megszakított megközelítési eljárás, így az eljárás során előforduló baleset valószínűségét 1-nek vesszük.

$P_x = 1{,}0$

Megjegyzés. - Ebben a példában alapfeltételként elfogadott az, hogy egy III. Kategóriájú üzemeltetésnél a légijármű vezetője a földi rendszer integritási meghibásodása esetén nem képes a közbelépésre. A kockázat csökkentő tényező ennek megfelelően 1-el egyenlő.

$P_u = 2{,}5 \times 10^{-4}$

Megjegyzés. - A légijárművezető kockázat csökkentő tényezője 4 000 esetben 1-re becsült érték, ami a megközelítést és a leszállást végrehajtó földi útirány-vezetési rendszereket felhasználó légijárművek baleseteinek tanulmányán alapszik. Ez a kockázat csökkentő tényező a szolgáltatás folyamatossági meghibásodást követően a légijárművezető közbelépését fogadja el.

Ennek megfelelően:

$P_i = 1 \times 10^{-9}$

$P_p = 4 \times 10^{-6}$

$P_d = 2{,}5 \times 10^{-4}$

$P_c = 4 \times 10^{-6} x 2{,}5 \times 10^{-4} = 1\ 10^{-9}$

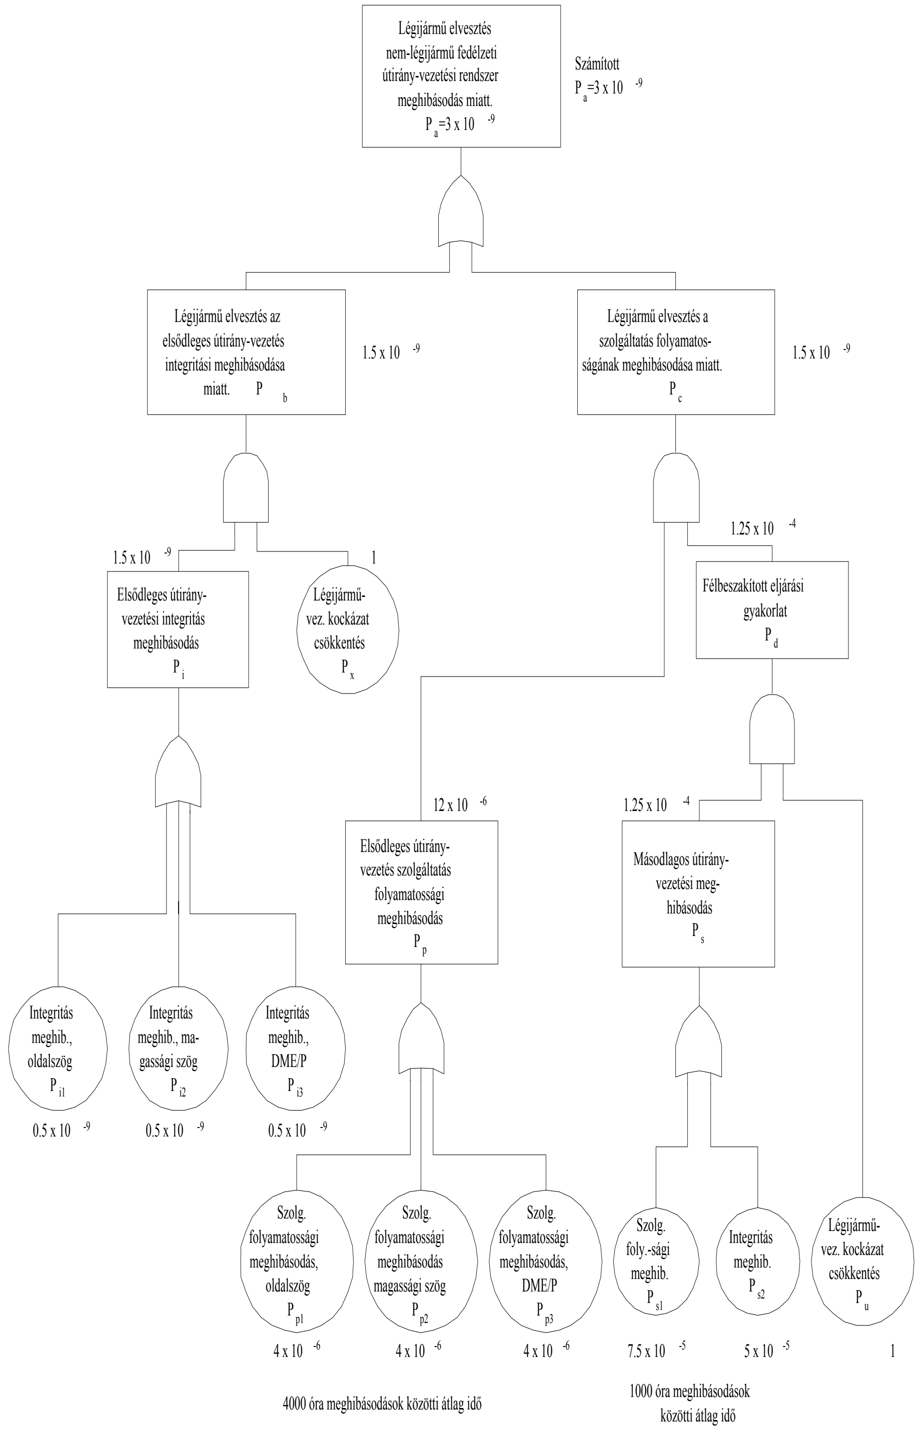
$P_b = 1 \times 10^{-9}\ 1$

és:

számított $P_a = 2 \times 10^{-9}$.

3.2 Ennek megfelelően ezért van egy 1×10^{-9} tűrés az általános követelményben.

4. *A kockázati fa alkalmazása az akadály-gazdag* környezetben végrehajtott MLS / RNAV üzemeltetésre (A-3. ábra).



A-3. ábra: MLS / RNAV akadály-gazdag környezeti kockázati fa

4.1 Ebben az esetben három navigációs egység szerepel (azaz oldalszög, magassági szög és DME / P), és mindegyiküknél alapfeltételként elfogadott az, hogy kielégítik a 4. szintű oldalszög adó berendezésre vonatkozó integritási és szolgáltatás folyamatossági (COS) követelményeket, azaz az integritás = 1 - 0,5 x 10^{-9} és a meghibásodások közötti átlagos idő MTBO = 4 000 óra.

$P_{i1} = P_{i2} = P_{i3} = 0{,}5 \times 10^{-9}$

$P_{x} = 1{,}0$

Megjegyzés. - Elfogadott az, hogy a légijárművezető nem képes arra, hogy a földi rendszer egy integritási meghibásodása esetében közbelépjen.

$P_{p1} = P_{p2} = P_{p3} = 4 \times 10^{-6}$

Megjegyzés. - Ez feltételezi azt, hogy az akadályok általi veszélyeztetettségi idő (OET) 60 másodperc, és a meghibásodások közötti átlagos idő 4 000 óra az összes földi egységre.

$P_{u} = 1{,}0$

Megjegyzés. - Feltételezett az, hogy egy útirány-vezetés nélküli félbeszakított megközelítési / megszakított megközelítési eljárás elfogadhatatlan. Ennek megfelelően egy ilyen eljárás során bekövetkező baleset valószínűségét 1-nek vettük.

4.2 Ebben az esetben az MLS / RNAV eljárás egy akadály-gazdag környezetben kerül végrehajtásra, és alapfeltételként elfogadott az, hogy a másodlagos útirány-vezetés elengedhetetlen lesz a biztonságos félbeszakított megközelítésnek / megszakított megközelítésnek az akadályok általi veszélyeztetettségi idő során történő végrehajtásához.

$P_{s_1} = 7{,}5 \times 10^{-5}$

Megjegyzés. - Ez a másodlagos útirány-vezetési földi berendezés szolgáltatás folyamatossági (COS) meghibásodásának valószínűsége. Itt elfogadott az, hogy a másodlagos útirány-vezetési rendszer meghibásodások közötti átlagos ideje (MTBO) 1 000 óra, és az akadályok általi veszélyeztetettségi idő 270 másodperc. A hiba fennállása általi veszélyeztetettségi idő a másodlagos útirány-vezetésre az eljárás azon pontjától függ, amelynél a másodlagos útirány-vezetés rendelkezésre állását megerősítik. Elfogadva azt, hogy ez az MLS / RNAV eljárás megkezdése előtt fog bekövetkezni,és nem lesz szükséges az, hogy a légijárművezető újra megerősítse a másodlagos útirány-vezetés rendelkezésre állását, az eljárás kritikus akadály-gazdag része megkezdése előtt, az akadályok általi veszélyeztetettségi idő több perc is lehet.

$P_{s_2} = 5 \times 10^{-5}$

Megjegyzés. - Ez az az integritás, ami a másodlagos útirány-vezetési rendszerhez szükséges.

Ennek megfelelően:

$P_{i} = 1{,}5 \times 10^{-9}$

$P_{b} = 1{,}5 \times 10^{-9}$

$P_{p} = 12 \times 10^{-6}$

$P_{s} = 7{,}5 \times 10^{-5} + 5 \times 10^{-5} = 1{,}25 \times 10^{-4}$

$P_d = 1,25 \times 10^{-4}$

$P_c = 12 \times 10^{-6} + 1,25 \times 10^{-4} = 1,5 \times 10^{-9}$

és:

számított $P_a = 3 \times 10^{-9}$, ahogy szükséges.

Megjegyzés. - A 60 másodpercnél nagyobb akadályok általi veszélyeztetettségi időnél az lesz szükséges, hogy vagy növeljék az elsődleges útirány-vezetés meghibásodások közötti átlag idejét, vagy növeljék a másodlagos útirány-vezetés miatti kockázat csökkentési tényezőt. Például, ha az akadályok általi veszélyeztetettségi idő 90 másodpercre növekszik, akkor az elsődleges útirány-vezetés meghibásodások közötti átlag idejét meg kell növelni 6 000 órára, vagy a másodlagos útirány-vezetés meghibásodások közötti átlag idejét 2 250 órára kell növelni. Nyilvánvaló kompromisszum van az elsődleges útirány-vezetés megbízhatósága, az akadályok általi veszélyeztetettségi idő és a másodlagos útirány-vezetés megbízhatósága és integritása között. A kockázati fa módszert fel lehet használni egy egyedi MLS / RNAV eljárás felülvizsgálatára, valamint az elsődleges és másodlagos útirány-vezetés megfelelő megbízhatósági és integritási követelményeinek meghatározására.

"B" MELLÉKLET: A MEGKÖZELÍTÉS ÉS LESZÁLLÁS NEM-LÁTÁSOS BERENDEZÉSEI BEVEZETÉSÉNEK ÉS ALKALMAZÁSÁNAK STRATÉGIÁJA

(lásd a 2. Fejezet 2.1 pontját)

1. Bevezetés

1.1 Különféle tényezők vannak hatással a minden időjárás melletti üzemeltetésekre a biztonság, a hatékonyság és a rugalmasság szempontjában kifejezve. Az új technikák fejlődése szükségesé teszi a minden időjárás melletti üzemeltetések fogalmának rugalmas megközelítését ahhoz, hogy a technikai fejlesztés összes előnyét megkapják. Ennek a rugalmasságnak a létrehozását egy stratégia teszi lehetővé, a stratégia mögötti gondolatok és célok azonosításán keresztül, és az új technikai fejlesztéseknek, vagy ötleteknek az ebbe a stratégiába való beépítésével.

1.2 A stratégia felkészít a nem-látásos berendezések alkalmazására a függőleges vezetéssel történő megközelítésre és leszállásra (APV), valamint a precíziós megközelítés és leszállás műveleteire.

2. A stratégia céljai

A stratégiának:

a) meg kell tartani a minden időjárás melletti üzemeltetéseknek legalább a jelenlegi biztonsági szintjét;

b) meg kell őrizni a szolgáltatásnak legalább a jelenlegi szintjét, vagy a tervezett javított szintet;

c) meg kell tartani az általános kölcsönös működőképességet;

d) egyeztetett körzeti tervezésen alapulóan körzeti rugalmasságot kell biztosítani;

e) alkalmazhatónak kell lenni legalább a 2015. évig; és

f) számításba kell venni a gazdaságossági, üzemeltetési és technikai kérdéseket.

3. Megfontolások

3.1 Általános rész

A következő megfontolások azon az előfeltételen alapulnak, hogy az üzemeltetési követelmények és a szükséges elkötelezettség rendelkezésre áll, és a szükséges erőfeszítéseket ráfordítják.

3.2 ILS vonatkozású megfontolások

a) Fennáll az a veszély, hogy a II. vagy III. kategóriájú ILS üzemeltetéseket bizonyos sajátságos helyeken nem lehet biztonságosan fenntartani;

b) az ILS vevők interferencia érzéketlenségi teljesítmény szabványokat az Annex 10, I. Kötet 3. Fejezet 3.1.4 pontja tartalmazza;

c) az ILS bővítését a rendelkezésre álló csatornák száma (40 csatorna) korlátozza;

d) sok öregedő ILS földi berendezést ki kell cserélni; és

e) a világ legtöbb területén az ILS fenntartható a belátható jövőben.

3.3 MLS vonatkozású megfontolások

a) Az MLS I. kategória üzemel;

b) a II. kategóriára alkalmas földi berendezés alkalmassági bizonyítványa megvan. A földi és fedélzeti IIIB berendezés alkalmassági bizonyítványa kidolgozás alatt van és 2004-2005 között fejeződik be előreláthatólag;

c) az MLS kivitelezése bizonyos helyekre tervezve van, hogy javítsa a felszállópálya felhasználhatóságát alacsony látási körülmények között is.

3.4 Műholdas Navigációs Világrendszer (GNSS) vonatkozású megfontolások

a) Szabványok és Ajánlott Gyakorlatok (SARPs) vannak életbe léptetve a GNSS számára kiegészítéssel, a Megközelítés Függőleges vezetéssel (APV) és az I. kategóriájú precíziós megközelítés támogatására;

b) Szabványok és Ajánlott Gyakorlatok (SARPs) vannak kidolgozás alatt a Földi Bázisú Regionális Kiegészítő Rendszer (GRAS) Megközelítés Függőleges vezetéssel (APV) számára.

c) a GNSS rendszerrel együttműködő Műhold Bázisú Kiegészítő Rendszer (SBAS) a Megközelítés Függőleges vezetéssel (APV) a világ néhány részében már működik.

d) a GNSS rendszerrel együttműködő Földi Bázisú Kiegészítő Rendszer (GBAS) az I. kategóriájú precíziós megközelítési műveletekhez várhatóan 2006-ban lép működésbe.

e) nem várható, hogy egy nemzetközileg elfogadott Műholdas Navigációs Világrendszer a kiegészítéseivel, ahogy szükséges, a II. és III. Kategóriájú üzemeltetésekre a 2010- 2015. közötti évek előtt rendelkezésre álljon.

f) a Műholdas Navigációs Világrendszerrel végrehajtott megközelítési, leszállási és indulási üzemeltetésekhez kapcsolódó technikai és üzemeltetési kérdéseket időszerű módon meg kell oldani;

g) a Műholdas Navigációs Világrendszerrel végrehajtott megközelítési, leszállási és indulási üzemeltetésekhez kapcsolódó rendszeresítési kérdéseket időszerű módon meg kell oldani;

3.5 Többféle végrehajtási utasítással ellátott fedélzeti megközelítési és leszállási képességgel kapcsolatos megfontolások

Ennek a stratégiának a lehetővé tételéhez egy többféle végrehajtási utasítással ellátott fedélzeti megközelítési és leszállási képesség szükséges, hogy rendelkezésre álljon.

3.6 Egyéb megfontolások

a) Növekvő igény van a II. és III. kategóriájú üzemeltetések iránt;

b) a GNSS potenciálisan egyedi üzemeltetési előnyöket tud biztosítani az alacsony látású üzemelésekhez, beleértve új eljárásokat, rugalmas telepítési követelményeket és a repülőtéri felszíni forgalomvezetés ellátását;

c) csak a három szabványos rendszer (ILS, MLS és a GNSS a kívánt kiegészítéssel) játszik szerepet az összes időjárási körülmények közötti ütemeltetések támogatásában. A szem elé vetített kijelzések, együttműködve a fejlett és/vagy szintetikus kijelző rendszerekkel, üzemeltetési előnyöket adhatnak.

d) A globális stratégia következménye, hogy nincs gyors átmenet az ILS-ből az új rendszerekre, mint a GNSS, vagy MLS. Különösen fontos a stratégia kiépítésekor, hogy a rendszerek által használt rádiófrekvenciás spektrum megfelelően védve legyen;

e) a gyakorlatban ajánlott a közvetlen átmenet az ILS-ből a GNSS-re. Néhány Államban ugyanakkor nem lehetséges ennek az átmenetnek a végrehajtása a II., vagy a III. Kategóriás jelenlegi üzemeltetési szint elvesztése nélkül;

f) amíg néhány felhasználó egy adott felszállópályánál továbbra is az ILS-re támaszkodik, az új leszállító rendszerek bevezetéséből származó üzemeltetési előnyöket korlátozhatja a több-rendszerű üzemeltetésekből származó hátrány.

g) az APV üzemeltetések irányíthatók GNSS-el, a szükséges kiegészítéssel együtt, vagy barometrikus függőleges vezetéssel, valamint ABAS, vagy DME/DME RNAV oldalirányú vezetéssel; és

h) az APV üzemeltetések magasszintű biztonságot és általában alacsonyabb üzemeltetési minimumot biztosítanak, összehasonlítva a nem-precíziós megközelítésekkel.

4. Stratégia

A fenti megfontolásokon alapulva és azzal a szükségességgel, hogy a légijárművek járatóival és a nemzetközi szervezetekkel – a biztonságot szem előtt tartva - konzultálni kell, az általános stratégia a következő:

a) folytatni kell az ILS üzemeltetéseket a szolgáltatás legmagasabb szintjén addig, amíg az üzemeltetésileg elfogadható és gazdaságosan előnyös, annak biztosításáért, hogy a repülőtér megközelítés ne legyen visszautasítva olyan repülőgép esetében, mely kizárólag ILS berendezéssel van felszerelve;

b) bevezetni az MLS-t ott, ahol üzemeltetésileg szükséges és gazdaságosan előnyös;

c) bevezetni a GNSS-t kiegészítéssel (ami ABAS, SBAS, GBAS), ahogy szükségszerű az APV és az I. kategóriájú üzemeltetések számára; ahol üzemeltetésileg szükséges és gazdaságosan előnyös, miközben biztosítani kell, hogy az egyenlítői régiókban az ionoszférikus terjedéssel kapcsolatos feladatokat kellő időben megállapítják és megoldják;

d) előmozdítani a többféle végrehajtási utasítással ellátott fedélzeti megközelítési és leszállási képesség kifejlesztését;

e) előmozdítani az APV üzemeltetések használatát, különösen azokat, melyeka GNSS függőleges vezetést használják, a biztonság és a megközelíthetőség fokozása érdekében;

f) üzemeltetési és technikai alkalmazhatósági feladatokat meghatározni és megoldani a GNSS számára, mely földi bázisú kiegészítő rendszerrel (GBAS) dolgozik és támogatja az I. és II. Kategóriájú üzemeltetéseket. Elő kell mozdítani a GNSS II. és III. Kategóriás üzemeltetéseket ott, ahol üzemeltetésileg szükséges és gazdaságosan előnyös; és

g) lehetővé tenni az egyes körzetekben, hogy kifejlesszék ezeknek a rendszereknek a bevezetésének stratégiáját az általános stratégiával párhuzamosan.

"C" MELLÉKLET: TÁJÉKOZTATÁSOK ÉS ÚTMUTATÓ ANYAG A SZABVÁNYOK ÉS AJÁNLOTT GYAKORLATOK-NAK AZ ILS-re, A VOR-ra, A PAR-ra, a 75 MHz-es (ÚTVONAL) HELYJELADÓKRA (ÚTVONAL), AZ NDB-re ÉS A DME-re TÖRTÉNŐ ALKALMAZÁSÁHOZ

1. Bevezetés

Az ebben a Mellékletben lévő anyag célja az, hogy útmutatásként, vagy tisztázó célokra szolgáljon, és nem tekinthető az előírások részének, vagy az I. Kötetben foglalt Szabványok és Ajánlott Gyakorlatok részének.

A következő szöveg megértésének tisztázása és az egymással szorosan kapcsolódó fogalmak gyors eszmecseréjének elősegítésére a következő meghatározásokat építettük be.

A Műszeres Leszállító Rendszerre (ILS) vonatkozó meghatározások

Megjegyzés. - Az itt megadott szakkifejezések a legtöbb esetben alkalmasak akár előtag nélküli, akár a "névleges" és a "kimutatott" előtaggal való alkalmazásra. Az ilyen szóhasználatban a következő jelentést közvetítik:

A "névleges" előtag: *valamely alkotóelem, vagy fogalom tervezési jellemzője.*

Előtag nélkül: *egy alkotóelem, vagy egy fogalom elért jellemzője.*

A "kimutatott" előtaggal: *valamely alkotóelem, vagy fogalom elért jellemzője, úgy, ahogy az egy vevőn kimutatásra került (azaz a vevő berendezés hibáit is beleértve).*

Iránysáv adó rendszer	ILS siklópálya rendszer

Slant course line. Lejtős irányvonal
Az útirány felület és az ILS siklópálya névleges síkjának metszése által kialakuló vonal.

	False ILS glide path. Hamis ILS siklópálya A futópálya középvonalát magába foglaló függőleges síkban lévő azon pontok helye, amelynél a modulációs mélység különbség (DDM) nulla, és nem azoknak a pontoknak a helyei, amelyek az ILS siklópályát képezik.

Displacement error. Eltolódási hiba
A nulla modulációs mélység különbség (DDM) bármely pontjának szögbeli, vagy hosszirányú eltérése a névleges iránysáv vonalhoz, vagy a névleges ILS siklópályához viszonyítva külön-külön.

Linearity sector. Lineáris szektor
Az útirány szektoron, vagy egy ILS siklópálya szektoron belül az az iránysáv vonalat, vagy az ILS siklópályát magába foglaló szektor, amelyen belül az eltérés egységenkénti DDM növekedés lényegében állandó marad.

Low DDM zone. Alacsony értékű DDM zóna
Az irány szektoron, vagy egy ILS siklópálya szektoron kívüli azon szektor, amelyben a modulációs mélység különbség (DDM) a zónán belülre meghatározott minimális értéknél kisebb.

Megjegyzés. - Az ilyen zónákra vonatkozó minimális DDM értékek a 3. Fejezet 3.1.3.7 és 3.1.5.6 pontjában kerültek meghatározásra.

Plane of the nominal ILS glide path. A névleges ILS siklópálya síkja
A futópálya meghosszabbított középvonalának függőleges síkjára merőleges és a névleges ILS siklópályát magába foglaló sík.

Indicated course sector. Kimutatott irányvonal
Bármely vízszintes síkban lévő azon pontok mértani helye, amelyeknél a vevő kimutatott eltérése nulla.

Indicated ILS glide path. Kimutatott ILS siklópálya
A futópálya középvonalát magába foglaló függőleges síkban azon pontok mértani helye, amelyeknél a vevő kimutatott eltérése nulla.

Indicated slant course line. Kimutatott lejtős irányvonal
A kimutatott irány felületnek és a névleges ILS siklópálya síkjának a metszése által kialakított vonal.

Indicated ILS glide path angle. Kimutatott siklópálya szög
A kimutatott ILS siklópályának a vízszintes sík feletti szöge.

Indicated course sector. Kimutatott irány szektor
A kimutatott irányvonalat magába foglaló bármilyen vízszintes síkban lévő azon szektor, amelyben a vevő kimutatott eltérése a teljes skála eltérés értéken belül marad.

Indicated ILS glide path sector. Kimutatott ILS siklópálya szektor
A kimutatott ILS siklópályát magába foglaló azon szektor, amelyben a vevő kimutatott eltérése a teljes skála eltérés értéken belül marad.

Localizer course bend. Iránysáv irányvonal elhajlás
Az irányvonal elhajlás az iránysáv irányvonalának a névleges helyzetéhez viszonyított eltérése.

ILS glide path bend. ILS siklópálya elhajlás
Az ILS siklópálya elhajlás az ILS siklópályának a névleges helyzetéhez viszonyított eltérése.

Incremental sensitivity. Differenciális érzékenység
A vevő kijelző műszer áramának növekedése a vevő antennának a névleges irányvonaltól, vagy a névleges ILS siklópályától való eltérésben bekövetkező egységnyi változása következtében.

Flat zone. Lapos zóna
A kimutatott irányszektoron, vagy egy kimutatott ILS siklópálya szektoron belül az a zóna, amelyen belül a szektor karakterisztika görbéjének hajlásszöge nulla.

Reversal zone. Tükörzóna
A kimutatott irányszektoron, vagy egy kimutatott ILS siklópálya szektoron belül az a zóna, amelyen belül a szektor karakterisztika görbéjének hajlásszöge negatív.

2. Az ILS berendezésekre vonatkozó anyag

2.1 A Berendezés Teljesítmény Kategória üzemeltetési céljai, tervezése és fenntartási céljai, valamint irány felépítésének meghatározása

2.1.1 A 3. Fejezet 3.1.1 pontjában meghatározott Berendezés Teljesítmény Kategóriákra a következő üzemeltetési célok vonatkoznak:

I. Kategóriájú üzemeltetés: Precíziós műszeres megközelítés és leszállás 60 m-nél (200 láb) nem alacsonyabb elhatározási magassággal és vagy 800 m-nél nem kevesebb látástávolság, vagy 550 m-nél nem kevesebb futópálya menti látástávolság mellett.

II. Kategóriájú üzemeltetés: Precíziós műszeres megközelítés és leszállás 60 m-nél (200 láb) alacsonyabb, de 30 m-nél (100 láb) nem alacsonyabb elhatározási magassággal, és 350 m-nél nem kevesebb futópálya menti látástávolság mellett.

III./A Kategóriájú üzemeltetés: Precíziós műszeres megközelítés és leszállás:

a) a 30 m-nél (100 láb) alacsonyabb elhatározási magassággal, vagy elhatározási magasság nélkül; és

b) 200 m-nél nem kevesebb futópálya menti látástávolság mellett.

III./B Kategóriájú üzemeltetés: Precíziós műszeres megközelítés és leszállás:

a) 15 m-nél (50 láb) alacsonyabb elhatározási magassággal, vagy elhatározási magasság nélkül; és

b) 200 m-nél kevesebb, de 50 m-nél nem kevesebb futópálya menti látástávolság mellett.

III./C Kategóriájú üzemeltetés: Precíziós műszeres megközelítés és leszállás elhatározási magasság nélkül és a futópálya menti látástávolság korlátozása nélkül.

2.1.2 Ezeknél a céloknál az ILS-t felhasználó légijármű típusa és a légijármű repülés vezérlő rendszere(i)nek teljesítőképessége lesz fontos. A modern légijárműveket már felszerelték az olyan megfelelő tervezésű berendezésekkel, amelyek elérik ezeket a célokat. A gyakorlatban azonban az üzemeltetési lehetőségek túlnyúlhatnak a fenti 2.1.1 pontban megadott meghatározott célokon.

2.1.2.1 A meghibásodás-érzéketlen és a meghibásodás esetén is üzemképes repülés vezérlő rendszerek rendelkezésre állása egy olyan ILS földi rendszerrel együtt, amely pontos irányvezetést biztosít a szolgáltatás folyamatosság és az integritás megfelelő szintjével, a különleges esetekre lehetővé fogja tenni az üzemeltetési célok olyan megvalósítását, amelyek nem ütköznek a fenti 2.1.1 pontban leírtakkal.

2.1.2.2 A modern automata megközelítési és leszállási rendszerekkel felszerelt légijárművek esetében az ilyen rendszerek mindennapi alkalmazását a légijárműveket üzemeltető vállalatok támogatják az olyan feltételeknél, amikor a légijárművek személyzete a megközelítés folyamatát látással ellenőrizni tudja. Például, ilyen üzemeltetéseket lehet végrehajtani az ILS - I. teljesítmény kategóriájú berendezéseken, ahol az irányvezetés minősége és fedésterülete meghaladja a 3. Fejezet 3.1.3.4.1 pontjában megadott alapkövetelményeket és egészen a futópályáig kiterjed.

2.1.2.3 Abból a célból, hogy a modern légijárművek automatikus repülőgép vezérlő rendszereinek lehetséges előnyeit teljes egészében kihasználják, egy összefüggő szükségesség merült fel egy olyan rendszer iránt, ami a földi telepítésű ILS berendezéseket annál jóval tökéletesebb módon írja le, mint ami egyedül a Berendezés Teljesítmény Kategória vonatkoztatással elérhető. Ez a három minősítési jellemzőt alkalmazó ILS osztálybasorolással érhető el. Ez azoknak a teljesítmény szempontoknak a leírását adja meg, amelyeket az üzemeltetések nézőpontjából tudni kell, abból a célból, hogy eldöntsék azt az üzemeltetési alkalmazást, amelyet a meghatározott ILS alá tud támasztani.

2.1.2.4 Az ILS osztályba-sorolási rendszer egy eszközt biztosít ahhoz, hogy megismertesse azokat a kiegészítő lehetőségeket, amelyek egy adott ILS földi berendezéstől rendelkezésre állnak, azokon túl, amelyek a 3. Fejezet 3.1.1 pontjában meghatározott berendezésekhez kapcsolódnak. Ezeket a kiegészítő képességeket lehet kiaknázni abból a célból, hogy lehetővé tegyék azt, hogy a fenti 2.1.2.1 és 2.1.2.2 pont szerinti üzemeltetési felhasználás engedélyezve legyen a fenti 2.1 pontban leírt üzemeltetési célokban megállapított értékekig és azok alá.

2.1.2.5 Az osztálybasorolási rendszer egy példája az alábbi 2.14.3 pontban kerül bemutatásra.

2.1.3 Az ILS I. és II. Üzemeltetési Teljesítmény Kategóriájú célok eléréséhez megfelelő fedélzeti berendezés tűréshatárokra vonatkozó útmutató anyagot az alábbi 2.2.4 és 2.2.5 pont adja meg. A megfelelő ILS berendezéseket felhasználó II. Kategóriájú üzemeltetések esetén megvalósítható lehet az, hogy engedélyezzék az üzemeltetéseket az alacsony megközelítési sebességű és kielégítően bizonyított manőverező képességű, a II. Kategóriára meghatározottaknál kevésbé szigorú tűréshatárú fedélzeti berendezéssel felszerelt légijárművek részére.

Megjegyzés. - A következő útmutató anyag célja az, hogy segítséget nyújtson az Államok részére akkor, amikor az elhajlással rendelkező ILS iránysáv adó irányvonalú és siklópályájú berendezések elfogadhatóságát értékelik. Jóllehet, a meghatározás szerinti irányvonal elhajlás és siklópálya elhajlás külön-külön az iránysáv adó irányvonalának és a siklópályájának a névleges helyzetéhez van vonatkoztatva, a nagyfrekvenciás eltérés értékelése a közepes irányvonaltól vagy pályától való eltérésen alapszik. A 2.16 pontban és a C-2. számú ábrán bemutatott, az elhajlások értékelésére vonatkozó anyag azt jelzi, hogy az elhajlások hogyan vonatkoznak az irányvonal, vagy a pálya közepes helyzetére. A légijármű fedélzeti regisztrálás szabályszerűen ebben a formában fog történni.

2.1.4 *Iránysáv vonal elhajlások.* Az iránysáv vonal elhajlásokat a 3. Fejezet 3.1.3.4 pontjában meghatározott irány felépítésben kifejezve kell kiértékelni. A III. Kategóriájú körülmények között végrehajtott leszállásokra és leszállás utáni kifutásra tekintettel ez az irány felépítés azon a kívánalmon alapszik, hogy kielégítő irány vezetés kerüljön biztosításra a kézi vezetési és / vagy automatikus üzemeltetésekre a futópálya felülete mentén az alacsony látástávolságú körülmények esetén. Az I. Kategóriájú teljesítményre tekintettel, a megközelítési szakaszban ez az irány felépítés azon a kívánalmon alapszik, hogy a légijárműnek az iránysáv vonal elhajlása miatti eltérését (a 95 százalékos valószínűségi alapon) a 30 méteres (100 láb) magasságban 10 méternél (30 láb) kevesebb oldalirányú eltolódásra korlátozzák. A II. és III. Kategóriájú teljesítményre tekintettel a megközelítési szakaszban ez az irány felépítés azon a kívánalmon alapszik, hogy a légijárműnek az iránysáv vonal elhajlása miatti eltérését (a 95 százalékos valószínűségi alapon) az ILS B-pontja és az ILS vonatkozási pontja közötti körzetben (II. Kategóriájú berendezések), vagy a D-pontja között (III. Kategóriájú berendezések) 2 foknál kisebb bedöntési és bólintási térbeli helyzetre és az oldalirányú eltolódását 5 méternél (15 láb) kevesebbre csökkentsék.

1. Megjegyzés. - Az iránysáv vonal elhajlások elfogadhatatlanok akkor, ha eleve megakadályozzák azt, hogy a légijármű szabályos körülmények között, stabil térbeli helyzetben és az iránysáv vonaltól való eltolódás elfogadható határértékein belül, olyan helyzetben érje el az elhatározási magasságot, ahonnan a biztonságos leszállás megvalósítható lesz. Az automatikus és a fél-automatikus ráállást nagyobb mértékben befolyásolhatja az elhajlások előfordulása, mint a kézi vezetési ráállást. Miután a légijármű ráállt a megközelítésre, egy erős kormánymozdulat megakadályozhatja a megközelítés, vagy a leszállás sikeres befejezését. Azonkívül, amikor automatikus ráállást használnak fel, akkor üzemeltetési követelmény lehet az is, hogy a megközelítést az elhatározási magasság alá is folytassák. A légijármű irányvezetése kielégítő lehet akkor, ha a 3. Fejezet 3.1.3.4 pontjában leírt irány felépítésre vonatkozó előírások kielégítésre kerültek.

2. Megjegyzés. - Az olyan elhajlásokat, vagy egyéb rendellenességeket, amelyek elfogadhatatlanok, általában precíziós légi ellenőrzési technikát igénylő stabil légköri állapotok mellett végrehajtott repülésekkel kell megállapítani.

2.1.5 *ILS siklópálya elhajlások.* Az elhajlásokat a 3. Fejezet 3.1.5.4 pontjában meghatározott ILS siklópálya irány felépítéséhez viszonyítva kell kiértékelni. Az I. Kategóriájú teljesítmény szempontjából a siklópálya irány felépítése azon a kívánalmon nyugszik, hogy a légijárműnek a siklópálya elhajlása miatti eltérését (a 95 százalékos valószínűségi alapon) a 30 méteres (100 láb) magasságban 3 méternél (10 láb) kisebb függőleges eltolódásra korlátozzák. A II. és III. Kategóriájú teljesítmény szempontjából a siklópálya irány felépítése azon a kívánalmon alapszik, hogy a légijárműnek a siklópálya elhajlás miatti eltérését (a 95 százalékos valószínűségi alapon) a 15 méteres (50 láb) magasságban 2 foknál kisebb bedöntési és bólintási térbeli helyzetre és a függőleges irányú eltolódásokat 1,2 méternél (4 láb) kisebbre korlátozzák.

1. Megjegyzés. - A siklópálya irányvonal elhajlások elfogadhatatlanok akkor, ha eleve megakadályozzák azt, hogy a légijármű szabályos körülmények között, stabil térbeli helyzetben és az ILS siklópályától való eltolódás elfogadható határértékein belül, olyan helyzetben érje el az elhatározási magasságot, ahonnan a biztonságos leszállás megvalósítható lesz. Az automatikus és a fél-automatikus ráállást nagyobb mértékben befolyásolhatja az elhajlások előfordulása, mint a kézi vezetési ráállást. Azonkívül, amikor automatikus ráállást használnak fel, akkor üzemeltetési követelmény lehet az is, hogy a megközelítést az elhatározási magasság alá is folytassák. A légijármű irányvezetése kielégítő lehet akkor, ha a 3. Fejezet 3.1.4.4 pontjában leírt irány felépítésre vonatkozó előírások kielégítésre kerültek.

2. Megjegyzés. - Az olyan elhajlásokat, vagy egyéb rendellenességeket, amelyek elfogadhatatlanok, általában - szükség szerint speciális földi mérésekkel kiegészített - precíziós légi ellenőrzéssel kell megállapitani.

2.1.6 *Az iránysáv irányvonal / siklópálya irányvonal elhajlásának nagyságára vonatkozó Szabvány alkalmazása.* Az iránysáv irány felépítésére (3. Fejezet 3.1.3.4 pont) és az ILS siklópálya irány felépítésére (3. Fejezet 3.1.5.4 pont) vonatkozó előírások alkalmazásánál a következő követelményeket kell alkalmazni:

- A C-1. számú ábra azt az összefüggést mutatja be, ami a maximális (95 százalékos valószínűségű) iránysáv irányvonal / /siklópálya irányvonal elhajlásának nagysága és a futópálya küszöbétől mért távolság között a II. és III. kategóriájú teljesítményre meghatározásra került.

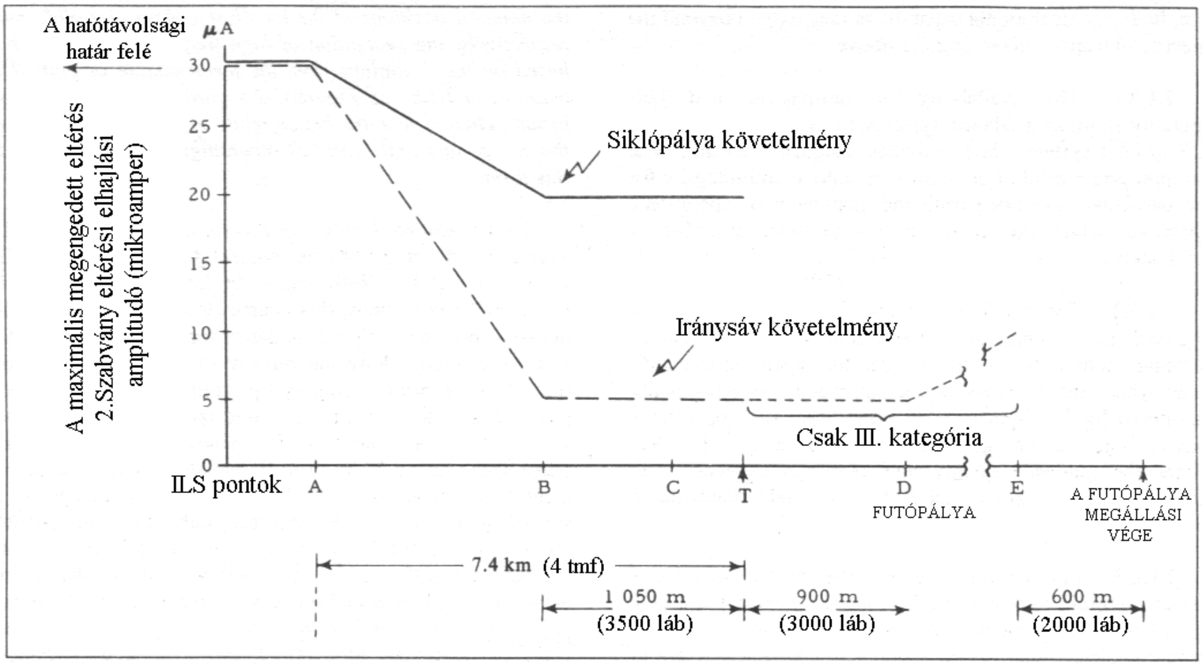
- Amikor az elhajlás nagyságát akarják a megközelítés bármely körzetében kiértékelni, akkor az ellenőrző repülés rögzített adatait - a légijármű szögbeli helyzet-hibájával helyesbítve - kell a kiértékelendő körzet középpontjához viszonyított plusz, vagy mínusz 20 másodperces időközre elemezni. A következők egy 195 km/órá-s (105 csomó) – plusz, vagy mínusz 9 km/óra (5 csomó) - légijármű föld feletti sebességen alapulnak.

A 95 százalékos maximális eltérési nagyság előírás annak a teljes időköznek a megengedhető százaléka, amelyben az irányvonal / siklópálya elhajlás nagyságának kevesebbnek kell lenni a C-1. ábrán meghatározott mennyiségnél a kiértékelés alatt álló körzetben. A C-2. számú ábra annak a módszernek egy jellemző példáját mutatja be, amit egy adott berendezés irányvonal / siklópálya elhajlás nagyságának kiértékelésére alkalmazni lehet. Ha a t_1, t_2, t_3 időközök összege - ahol az adott előírás túllépésre kerül - a teljes időnek, a 'T'-nek az 5 százalékával egyenlő, vagy annál kevesebb, akkor az a körzet, amelyet értékelnek, elfogadható. Ennek megfelelően:

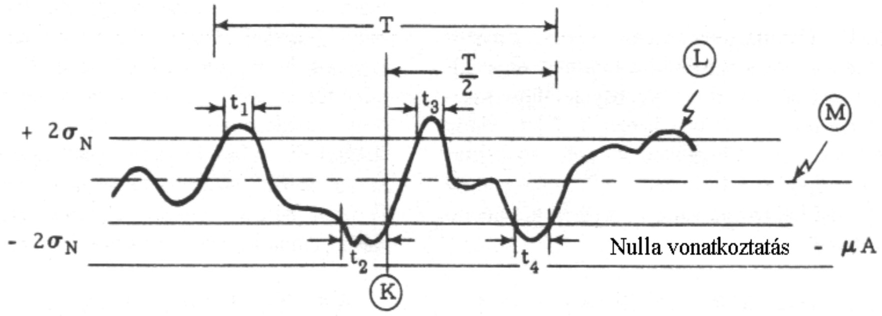
$$100\,\frac{T - [(t_1 + t_2 + \ldots)]}{T} \geq 95\%$$

Az ILS siklópálya elhajlások elemzésénél a közepes siklópályát kell alapadatként felhasználni, és nem a lefelé meghosszabbított egyenes vonalat. A görbület mértékét a földi berendezés siklópálya adó antenna rendszerének oldalirányú eltolt helyzete, az ennek az antenna-rendszernek a futópálya küszöbtől való távolsága és a végső megközelítési útvonal mentén lévő és a siklópálya adó telepítési helyén lévő talajfelszín relatív magasság szabályozza (lásd az alábbi 2.4 pontot).

2.1.7 Az ILS sugárnyaláb elhajlás felépítésében jelen lévő összetett frekvencia elemek következtében a sugárnyaláb elhajlás mért értékei a fedélzeti vevő berendezés és a rögzítő berendezés frekvencia jelleggörbéjétől függenek. Az a cél, hogy az elhajlás méréseket úgy szerezzék meg, hogy a teljes időállandót (másodpercekben) a vevő modulációs mélység különbségének (DDM) kimeneti áramkörére és a kapcsolódó rögzítő berendezés 92,6/*V* értékére alkalmazzák, ahol a *V* a légijármű vagy, a földi jármű - amelyik a megfelelő - sebessége km/órában.



C-1. ábra: A II. és III. kategóriájú iránysáv irányvonal és siklópálya maximális elhajlási nagyságának követelménye



(L) = Teodolittal helyesbített iránysáv irányvonal/siklópálya irányvonal elhajlási minták (mikroamper)

(M) = Az iránysáv irányvonal/siklópálya irányvonal elhajlásának középértékei (mikroamper)

T = A kiétrékelendő körzet ($\pm$20 másodperc széles)

$\pm 2\sigma_N$ = A maximális elhajlási nagyság előírás a (K) pontnál (mikroamper)

t_1, t_2, t_3, ... = Azok az időtartamok, ahol a zaj meghaladja a megengedhető $2\sigma_N$ értéket.
A berendezésre ebben a körzetben elfogadható érték:

$$100\,\frac{[T-(t_1+t_2+t_3\ldots)]}{T} \geq 95\%$$

C-2. ábra: Az iránysáv irányvonal / siklópálya irányvonal elhajlási magasságának (amplitúdójának) kiértékelése

2.1.8 *Felügyelő rendszer.* A rendelkezésre álló bizonyítékok azt jelzik, hogy a 3. Fejezet 3.1.3.6, 3.1.3.7 és 3.1.5.6 pontjában meghatározott határértékeken belüli teljesítmény stabilitás jóval a felügyelő rendszer határértékein belül teljes mértékben elérhető.

A folyamatos ellenőrzési határértékek kiválasztása az üzemeltetési kategória biztonsági követelményének ismeretével alátámasztott döntésen alapszik. Azonban az ilyen folyamatos ellenőrzési határértékekre vonatkozó előírások nem jelezhetik azokat a szabályos napról - napra változó teljesítmény értékeket, amelyek a beállítási hibákból és a berendezés ingadozásaiból eredhetnek. Ki kell vizsgálni és meg kell tenni a szükséges javító intézkedéseket akkor, ha a teljesítmény napról - napra gyakran ingadozik, a 3. Fejezet 3.1.3.6 , 3.1.3.7 és 3.1.5.6 pontjában meghatározott határértékeken belül. Az ilyen ingadozások okait ki kell küszöbölni:

a) az előírt ellenőrzési határértékek közelében ingadozó kritikus jel paraméterek lehetőségének nagymértékű csökkentésével;

b) az ILS szolgáltatás nagymértékű folyamatosságának biztosításával.

A következőkben néhány általános irányelvet adunk meg a felügyelő rendszerek tervezéséhez, üzemeltetéséhez és karbantartásához azért, hogy megfeleljenek a 3. Fejezet 3.1.3.11 és 3.1.5.7 pontja követelményeinek.

1) Nagyon gondosan kell eljárni annak biztosításánál, hogy a felügyelő rendszer válaszoljon a földi berendezés minden olyan eltérésére, ami kedvezőtlenül befolyásolhatja a légijármű fedélzeti rendszer üzemelését az ILS megközelítés során.

2) A felügyelő rendszernek nem szabad olyan helyi körülményekre reagálni, amelyek nincsenek hatással a fedélzeti rendszerek által észlelt navigációs információkra.

3) A felügyelő rendszer berendezése ingadozásainak nem szabad észrevehetően csökkenteni, vagy növelni a meghatározott ellenőrzési határértékeket.

4) Különleges körültekintéssel kell eljárni a felügyelő rendszer tervezésénél és üzemeltetésénél annak a célkitűzésnek a biztosításával, hogy a navigációs összetevők eltávolításra kerüljenek, vagy a sugárzást leállítsák magánál a felügyelő rendszernek a meghibásodása esetén.

5) Néhány felügyelő rendszer olyan berendezésekre támaszkodik, amelyek a jel mintákat az adó antenna-rendszer szomszédságában veszik. A tapasztalatok azt mutatják, hogy az ilyen felügyelő rendszerek külön figyelmet igényelnek a következő szempontokból:

a) ahol nagy nyílásszögű antenna-rendszereket alkalmaznak, ott gyakran nem lehetséges a felügyelő rendszer érzékelőit olyan helyen elhelyezni, hogy az érzékelési pontban a megfigyelt fázis szabály az irányvonalon a távoli-térben is fennálljon. Ennek ellenére a felügyelő rendszernek ki kell mutatni azokat az antenna és a hozzá kapcsolódó tápvonal rendszer változásokat is, amelyek jelentősen befolyásolják a távol-térben az irányvonalat;

b) a hó, állóvíz stb. okozta tényleges talajszint változások is befolyásolhatják a siklópálya felügyelő rendszerének működését és különbözően a tényleges térbeli irányvonalat, különösképpen akkor, amikor a megkívánt siklópálya sugárzási karakterisztikát a talaj síkjára vonatkoztatva alakítják ki;

c) figyelmet kell fordítani azokra az egyéb okokra is, amelyek zavarhatják a kisugárzott jel folyamatos ellenőrző érzékelését, az olyanokat, mint például a jegesedés, madarak stb.;

d) az olyan rendszereknél, ahol az ellenőrző jeleket egy visszacsatoló hurokban használják fel a megfelelő berendezés ingadozásának helyesbítésére, különleges figyelmet kell fordítani arra, hogy a magában a felügyelő rendszerben bekövetkező kívülálló hatások, vagy változások ne hozzák létre az irányvonalnak, vagy az ILS siklópályának az előírt határértékeken kívülre történő eltérését anélkül, hogy az a felügyelő rendszert riasztaná.

6) A folyamatos ellenőrzés egy lehetséges formája az olyan egybeépített felügyelő egység alkalmazása, amelyben az egyes sugárzó antenna elemeknek a távoli-térbeli irányvonal jel létrehozásához való hozzájárulását mérik magánál az antenna- rendszernél. A tapasztalat azt mutatta, hogy az ilyen felügyelő rendszerek - megfelelően felépítve - meg tudják adni a felügyelő jelzés és a távoli-térbeli kisugárzott jel közötti szoros kölcsönös viszonyt. Az ilyen típusú felügyelő rendszer bizonyos körülmények között megoldja a fenti 5) a), b) és c) pontban leírtakat.

Tudatában kell lenni annak, hogy a bármilyen térbeli pontban mért modulációs mélység különbség az elmozdulási érzékenység és az irányvonal, vagy az ILS siklópálya helyzetének függvénye. Ezt figyelembe kell venni a felügyelő rendszerek tervezésénél és üzemeltetése során.

2.1.9 *Az üzemeltetési használaton kívüli ILS iránysáv adók sugárzása.* Az üzemelő ILS iránysáv adók jeleinek erős zavarását tapasztalták a kis magasságokban megközelítéseket végrehajtó légijárművek az olyan futópályáknál, amelyek az ellentétes irányt kiszolgáló iránysáv adó berendezésekkel vannak felszerelve. Az ezeket az iránysáv adó rendszereket átrepülő légijárműveken a zavart (interferenciát) az ellentétes irányú megközelítés iránysáv adójából kisugárzott jelek keresztmodulációja okozza. Az ilyen interferencia, a kis magasságú üzemeltetések esetében, komolyan befolyásolhatja a megközelítést, vagy a leszállást, és károsan befolyásolhatja a biztonságot. A 3. Fejezet 3.1.27, 3.1.2.7.1 és 3.1.2.7.2 pontja határozza meg azokat a körülményeket, amelyek mellett az üzemeltetési használatban nem álló iránysáv adók sugárzása megengedhető.

2.1.10 Az *ILS többutas interferenciája a sugárzást visszaverő tárgyak és földi mozgások miatt*

2.1.10.1 Az ILS jelek interferenciájának előfordulása az ILS antennák körüli teljes környezettől és az antenna sugárzási karakterisztikájától függ. Bármilyen nagy sugárzást visszaverő tárgy - beleértve a

járműveket és az olyan állandóhelyű akadályokat is, mint az építmények - a kisugárzott jel fedésterületen belül potenciálisan létrehozhatja az ILS iránysáv vonal és siklópálya irány felépítésének többutas interferenciáját. A sugárzást visszaverő állandóhelyű akadályok és építmények mérete és helye az antennák irányítottsági minőségével együtt fogja meghatározni azt a statikus iránysáv, vagy siklópálya irány felépítési jellemzőt, hogy I., II., vagy III. kategóriájú lesz-e. A mozgó tárgyak lecsökkenthetik ezt az irány felépítést olymértékben, hogy az elfogadhatatlanná válik. Azt a területet, amelyen belül a lecsökkentő interferencia lehetséges, meg kell határozni és azonosítani kell.
A védőzóna kialakítása céljából ezeket a területeket két típusúra lehet felosztani, kritikus területekre és érzékenységi területekre:

a) az ILS kritikus terület egy, az iránysáv és a siklópálya adók körül kijelölt meghatározott méretű terület, ahonnan a járművek - a légijárműveket is beleértve - az összes ILS üzemeltetés végrehajtása során ki vannak zárva. A kritikus terület azért védett, mert a járműveknek és/ /vagy a légijárműveknek a határain belüli jelenléte az ILS térbeli jelek elfogadhatatlan zavarását fogják létrehozni;

b) az ILS érzékenységi terület egy, a kritikus területen kívülre kiterjedő terület, ahol a parkoló és/vagy mozgó járműveket - a légijárműveket is beleértve - ellenőrzik azért, hogy megakadályozzák az ILS jeleknek az ILS üzemeltetések során előforduló elfogadhatatlan interferenciájának lehetőségét. Az érzékenységi terület a kritikus területen kívüli, de a még általában a repülőtér határain belüli nagy mozgó tárgyak által okozott interferencia ellen biztosít védelmet.

1. Megjegyzés. - A kritikus és érzékenységi területek meghatározásának célja az, hogy kielégítő védelmet adjanak az ILS részére. Az a mód, amely szerint a szakkifejezést alkalmazzák, az Államok között változó lehet. Néhány Államban a kritikus terület kifejezést alkalmazzák még annak a területnek a leírására is, amelyre itt érzékenységi területként utaltunk.

2. Megjegyzés. - Arra lehet számítani, hogy olyan telepítési helyeken, ahol az ILS és az MLS együtt van telepítve, ott az MLS-t az ILS kritikus területen belül lehet elhelyezni, a "G"- Melléklet 4.1 Részében lévő útmutató anyagnak megfelelően.

2.1.10.2 A kritikus és érzékenységi területeknek azokat a jellemző példáit, amit védeni kell, a C-3A., C-3B., C-4A. és C-4B. számú ábra mutatja be. A kritikus terület védelménél az szükséges, hogy szabályszerűen tiltsák meg minden járműnek és a guruló, vagy parkoló légijárműveknek az erre a területre történő belépését valamennyi ILS üzemeltetés idejére. Az egyes iránysáv adóra és siklópálya adóra meghatározott kritikus területet egyértelműen ki kell jelölni. Megfelelő jelző eszközöket kell biztosítani azon gurulóutaknál és utaknál, amelyek a kritikus területbe behatolnak, azért, hogy kitiltsák a járműveket és a légijárműveket. Az érzékenységi területre vonatkozóan szükséges lehet az, hogy az összes mozgó forgalmat, vagy annak egy részét kitiltsák a lehetséges interferenciától és az üzemeltetés kategóriájától függően. Célszerű lehet a repülőtér határainak olymódon való kijelölése, hogy az magába foglalja az összes érzékenységi területet azért, hogy megfelelő ellenőrzést tudjanak biztosítani minden mozgó forgalom felett az ILS jeleinek elfogadhatatlan interferenciája megakadályozása céljából. Ha ezek a területek a repülőtér határvonalain kívülre esnek, akkor elengedhetetlen az, hogy a megfelelő hatóságokkal együttműködve, kieszközöljék a megfelelő ellenőrzés biztosítását. Üzemeltetési eljárásokat kell kifejleszteni az érzékenységi területek védelmére.

2.1.10.3 Az érzékenységi terület mérete számos tényezőtől függ, ezek az ILS antenna típusa, a terepfelszín, a mesterséges akadályok mérete és iránya, a nagy légijárműveket és járműveket is beleértve. A modern felépítésű iránysáv és siklópálya antennák nagyon hatékonyak lehetnek a zavaró lehetőségek csökkentésében, és ebből eredően az érzékenységi területek méretében. A miatt a lehetőség miatt, hogy a nagyobb típusú légijárművek nagyobb mértékben zavarják az ILS jeleit, ezekre a légijárművekre az érzékenységi terület egy jelentős távolsággal kiterjed a kritikus területen kívülre. A problémát súlyosbítja a megnövekedett földi forgalom-sűrűség.

2.1.10.3.1 Az iránysáv adó esetében az antenna fő irányú sugárzása által "megvilágított" minden nagyobb akadályt úgy kell tekinteni, mint az elfogadhatatlan jel interferencia lehetséges forrását. Ez magába foglalja a futópályán és a néhány gurulóúton lévő légijárműveket is. Az I., II. és III. Kategóriájú üzemeltetések védelmére szükséges érzékenységi területek méretei eltérőek lesznek, és a legnagyobb az lesz, ami a III. Kategóriához szükséges. Csak a legkisebb zavaró hatás engedhető meg a III. Kategóriára, de egy, a tűréshatáron kívüli irányvonal a futópálya felszíne mentén nem fogja befolyásolni az I. vagy II. Kategóriájú üzemeltetéseket. Ha az irány felépítés már a statikus többutas hatások miatt határértékű, akkor egy kismértékű további interferencia elfogadhatatlan jelet fog létrehozni. Az ilyen esetekben lehet, hogy egy nagyméretű érzékenységi területet kell elfogadtatni.

2.1.10.3.2 A siklópálya esetében a tapasztalat azt mutatja, hogy bármilyen olyan tárgyat, ami a siklópálya antenna szimmetria síkja fölé benyúlik, és az antenna oldalszög fedésterületen belül van, a jel lehetséges interferencia forrásaként kell tekinteni. Az antenna vízszintes síkja feletti felület szöge a használatos siklópálya antenna-sor típusától függ. Amikor nagyon nagy légijárművek parkolnak, vagy gurulnak a siklópálya antennától mért néhány-ezer lábon belül, vagy közvetlenül az antenna és a megközelítési siklópálya között, akkor rendszerint komoly zavart okoznak a siklópálya jelben. Másrészről a siklópálya antennától mért néhány-száz lábon túl lévő kis légijárművek hatása viszont elhanyagolhatónak látszik.

2.1.10.3.3 A tapasztalatok azt mutatják, hogy az ILS jelek visszatükröződésére és sugáreltérítésére hatással lévő azon fő tényezők, amelyek a többutas terjedési interferenciát létrehozzák, a magas és a légijárművek és járművek függőleges beállítású felületei. A valószínűleg elfogadható függőleges felület maximális magasságát a "legkedvezőtlenebb elhelyezkedésű helyzettel" együtt meg kell határozni. Ennek az oka az, hogy bizonyos elhelyezkedés határértéken kívüli iránysáv, vagy siklópálya eltéréseket okozhat nagyobb távolságokban is, mint a párhuzamos, vagy merőleges elhelyezkedések.

2.1.10.4 Számítógépes, vagy modellező technikát lehet alkalmazni az akadályok által okozott ILS zavarás valószínű helyének, nagyságának és időtartamának az olyan kiszámítására, hogy a különféle méretű és elhelyezkedésű légijárművek, vagy szerkezetek a különböző helyeken hogyan hozhatják létre. Az ezekkel a technikákkal foglalkozó kiadványok a következőket foglalják magukba:

a) általános használatúak a számítógépes matematikai modellek, és ezeket széleskörű gyakorlati szinttel rendelkező személyek alkalmazzák. Azonban a megfelelő előfeltételek és korlátozások mérnöki ismeretére és megítélésére van szükség akkor, amikor az ilyen modelleket a speciális többutas környezetben alkalmazzák. Az erre a tárgyra vonatkozó ILS teljesítmény tájékoztatásokat általában az ILS berendezések gyártói bocsátják rendelkezésükre;

b) ahol egy ILS telepítésre került és kielégítőnek találták, ott számítógépeket és szimulációs technikát lehet alkalmazni az olyan ILS zavarás valószínű mértékének előrejelzésére, ami egy javasolt új építmény építésének eredményeként létrejöhet. Ahol az lehetséges, ott az ilyen számítógéppel segített szimuláció eredményeit az új építmény felépítése utáni tényleges repülési mérések eredményeivel való közvetlen összehasonlítással kell megerősíteni; és

c) a földön lévő légijáművek miatti maximális megengedett többutas jel csökkenést figyelembe véve meg lehet határozni a megfelelő minimális érzékenységi terület határvonalait. A C-3A, C-3B, C-4A és C-4B ábrákon megadott modellek használatosak a kritikus és az érzékenységi területek meghatározására a földön lévő légijárművek miatti maximális megengedett többutas ILS jel csökkenés figyelembe vételével. Azok a tényezők, amelyek a kritikus és érzékenységi területek méretére és alakjára hatnak, magukba foglalják: az interferenciát okozható légijármű típusokat, az antenna apertúráját és típusát (log-periódikus dipól/dipól stb.), a fedősáv jelek típusát (egy/kettős frekvencia), a javasolt üzemeltetési kategóriát, a futópálya hosszát, a meglévő építmények által okozott statikus elhajlásokat. A modellek ilyen alkalmazása magába kell, hogy foglalja azok “érvényesítését”, ami a számított eredményeknek a leparkolt légijárművek ILS jelre gyakorolt interferenciája tényleges helyszíni kimutatott adataival való összehasonlítását foglalja magába.

	1. Példa	*2. Példa*	*3. Példa*
Légijármű típus	B-747	B-747	B-727
Az iránysáv adó antenna sugárzási szöge	Jellemzően 27 m (90 láb) (Irányított két-frekvenciás, 14-elemes)	Jellemzően 16 m (50 láb) (Fél-irányított, 8-elemes)	Jellemzően 16 m (50 láb) (Fél-irányított, 8-elemes)
Érzékenységi terület (X, Y)			
I. kategória X Y	600 m (2000 láb) 60 m (200 láb)	600 m (2000 láb) 110 m (350 láb)	300 m (1000 láb) 60 m (200 láb)

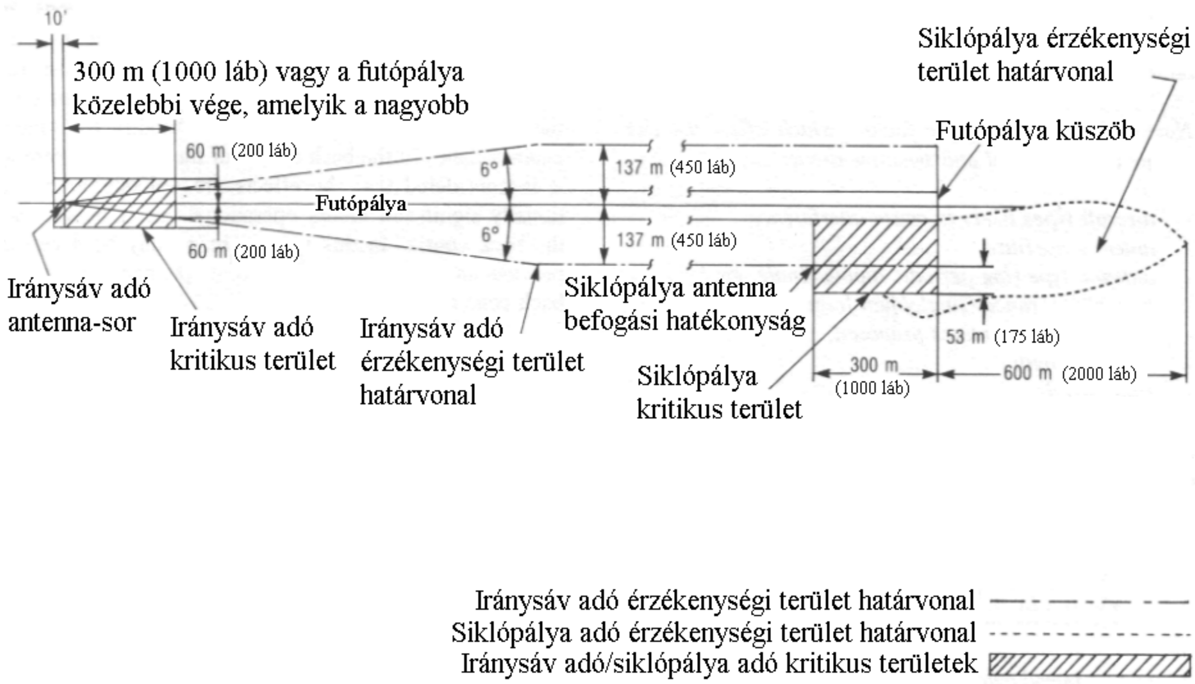
(Nem méretarányos)

C-4A. ábra: Példa a kritikus és érzékenységi területek alkalmazására speciális telepítési helyen B-747 típusú repülőgép által okozott interferenciánál

III. kategóriájú ILS iránysáv adó és siklópálya kritikus
és érzékenységi területek 24-elemes (50 m [164 láb])
iránysáv adó antennára (irányított).
Siklópálya antenna befogási hatékonyság.



C-4B. ábra: Példa a kritikus és érzékenységi területek alkalmazására speciális telepítési helyen B-747 típusú repülőgép által okozott interferenciánál

2.1.10.5 A kritikus területek ellenőrzése és az érzékenységi területek kijelölése lehetséges, hogy nem lesz elég az ILS-nek a nagy állandóhelyű földi szerkezetek által okozott többutas jelterjedés hatása elleni védelmére. Ez különösen akkor fontos, amikor az új, nagyobb légijárművek kiszolgálására szolgáló új épületek méreteit és egyéb célokat vesznek figyelembe. A repülőtér határain kívüli építmények is nehézségeket okozhatnak az ILS útirányok minőségénél még akkor is, ha azok megfelelnek az akadályok magasságára vonatkozó követelményeknek.

2.1.10.5.1 Ha a repülőtér környezetében olyan nagy állandóhelyű akadályok vannak, mint például magas épületek, amelyek azt idézik elő, hogy az iránysáv és / vagy a siklópálya irány felépítése közel van az üzemeltetési kategória tűréshatárához, akkor jóval nagyobb érzékenységi területek meghatározására lehet szükség. Ennek az az oka, hogy az ILS védelmére tervezett érzékenységi területeknél az állandóhelyű akadályok által okozott statikus sugárnyaláb elhajláshoz hozzá kell tenni a mozgó tárgyak hatását is. Azonban, a maximális elhajlási nagyság közvetlen hozzáadását nem lehet megfelelőnek tekinteni, és így a négyzetes középérték kombinációját tekintik jóval valósághűbbnek. A példák a következők:

a) az iránysáv irányvonal elhajlása statikus akadályok miatt plusz, vagy mínusz 1 ½ μA-el egyenlő. A tűréshatár plusz, vagy mínusz 5 μA. Ennek megfelelően a mozgó akadály miatt figyelembe vett tűrés az iránysáv adó érzékenységi területének meghatározásához:

$$\sqrt{5^2 - 1.5^2} = 4.77\mu A$$

b) az iránysáv irányvonal elhajlása a statikai akadályok miatt plusz, vagy mínusz 4 µA-el egyenlő. A tűréshatár plusz, vagy mínusz 5 µA. Ennek megfelelően a mozgó akadály miatt figyelembe vett tűrés az iránysáv adó érzékenységi területének meghatározásához:

$$\sqrt{5^2 - 4^2} = 3\mu A$$

A b) esetben az érzékenységi területnek nagyobbnak kell lenni, hogy ezáltal távolabb tartsa a zavart okozó tárgyakat a futópályától úgy, hogy azok az iránysáv sugárnyalábban 3 µA-es, vagy annál kisebb torzulást hozzanak létre. Ugyanezt az alapelvet kell alkalmazni a siklópálya érzékenységi területre.

2.1.11 *Útmutató anyag az ILS iránysáv elhajlási vonatkozású teljesítmény javításának üzemeltetési szempontjaihoz*

2.1.11.1 *Bevezetés.* Bizonyos helyeken a helyszínnek betudhatóan nem mindig lehetséges egyszerű szabványos ILS berendezéssel olyan iránysáv irányvonalat létrehozni, ami kielégítő mértékben mentes a zavaró elhajlásoktól, vagy rendellenességektől. Az ilyen berendezés telepítéseknél gyakran lehetséges lesz az, hogy az iránysáv irányvonal elhajlásait és rendellenességeit kielégítő mértékben csökkentsék olyan különféle módszerekkel, amelyek többsége az ebben az Annex-ben lefektetett előírásoktól bizonyos eltérések elfogadását kívánja meg, üzemeltetési szempontú esetleges hátrányokkal együtt.

2.1.11.2 *A javulást létrehozó módszerek.* Általában véve az iránysáv irányvonalának az elhajlások, vagy rendellenességek szempontjából történő javítását a sugárzásnak bizonyos irányokba való korlátozásával lehet létrehozni úgy, hogy elkerüljék, vagy minimálisra csökkentsék azokat az akadályok általi sugárzás visszaveréseket, amelyek az elhajlásokat növelik. Az olyan esetek többségében, ahol különleges kezelés szükséges, azt az akadályok irányába elhelyezett és telepített árnyékolások alkalmazásával lehet elérni. Ahol a sugárzást visszaverő akadályok száma nagy, vagy nagyméretűek, ott azonban az lehet szükséges, hogy az iránysáv adó majdnem teljes sugárzását egy, az iránysáv vonalra központosított keskeny szektorra korlátozzák. Az egyes módszerek bizonyos hátrányokkal járhatnak, amelyeket mérlegelni kell az egyedi berendezések esetében, a berendezésre épített különleges üzemeltetési alkalmazások és a következő megfontolások figyelembevételével.

2.1.11.3 *Az előzőekben említett javításokat létrehozó módszerek hátrányai*

2.1.11.3.1 A sugárzást a kiválasztott irányokban korlátozó árnyékolások alkalmazása általában az ILS két moduláló jele közötti különbséget csökkenti valamilyen más irányban avval a következménnyel, hogy az ILS kijelző műszer mutatója a közép fele mozdulhat el akkor, amikor a légijármű az ebben az irányban lévő területen áthalad. Azonban általában ez úgy tekinthető, hogy az ilyen kitérések üzemeltetési szempontból nem jelentősek, vagy megfelelő eljárások kidolgozásával áthidalhatók. Bizonyos alkalmazásoknál a jeleknek az irányszektorban, -ahol a jeleknek az árnyékoló rácsokkal, vagy reflektorokkal történő felerősítését alkalmazzák -, az árnyékoló rácsok, vagy reflektorok módosítani fogják az iránysáv adó hatótávolságot és az iránysáv hátsó irányszektorának jellemzőit. Itt azonban ismét úgy lehet tekinteni, hogy a hatások üzemeltetési szempontból valószínűleg nem jelentősek, kivéve azt, ha a hátsó irányszektor üzemeltetési felhasználását alkalmazzák. Ebben az utóbbi esetben szükséges lehet egy olyan további berendezés biztosítása, ami a hátsó irányszektort kiegészíti, vagy helyettesíti.

2.1.11.3.2 Ahol az szükséges, hogy az iránysáv adó sugárzását egy széles szektorban korlátozzák, és annak nagyobb részét az iránysáv adó első sugárnyalábjára összpontosítottan kell leszűkíteni, abból a célból, hogy az elhajlásokat kielégítő mértékben lecsökkentsék, ott a hátrányok általában a következők lesznek:

1) Az iránysáv adó tájékozódási információja abban a szektorban, amelyben a sugárzás le van szűkítve, vagy többé nem áll rendelkezésre, vagy nem lesz megbízható.

2) Gyakorlatilag megvalósíthatatlan lesz a fedélzeti vevő-rendszernek a jelölő rendszer általi előzetes ellenőrzése addig, míg a légijármű az iránysáv vonal középpontú szektoron belül van.

3) Az iránysáv vonal középpontú szektoron kívül eső területen bizonyos irányokban kielégítő sugárzás fordulhat elő ahhoz, hogy a légijármű fedélzeti ILS kijelzőt egy olyan bizonytalan módon működtesse, ami hamis kijelzésig történő növekedést adhat.

4) A hátsó irányszektor elvesztése.

2.1.11.3.3 Az 1) pontra vonatkozólag az a vélemény, hogy a tájékozódási információ szükséges, de a gyakorlat azt mutatja, hogy az ilyen információ minden esetben lehetőleg megszerezhető egy olyan kiegészítő berendezéstől, mint például egy helyjeladó. Egy ilyen kiegészítő berendezésre akkor lesz szükség, amikor az iránysáv adó sugárzása az iránysáv vonalra központosuló szűk szektorra korlátozódik. A 2) pontra vonatkozólag az a vélemény, hogy a vevő ellenőrzésének az iránysáv vonalra központosuló szektorba történő belépés előtti elvesztése üzemeltetési szempontból elfogadható.

2.1.11.3.4 A 3) pontban jelzett hátrány bizonyos esetekben komoly akadály lehet. Általában az a vélemény, hogy ennek a hátránynak az elfogadhatósága azon múlik, hogy milyen mértékű hamis kijelzés fog jelentkezni egy adott helyen, valamint az ILS berendezés felhasználásához létrehozott, vagy előírt eljárásoktól. Gyakorlatilag lehetséges olyan eljárások kidolgozása, amelyeknél az iránysáv adó jeleit mindaddig nem használják fel, amíg a légijármű nem képes ellenőrizni azt, hogy a felhasználható szektoron belül van. A tapasztalatok azt mutatják, hogy egy üzemeltetési használatban lévő berendezés esetében - eljárási szempontból - nem merül fel nehézség az irányszektoron kívüli bizonytalan műszer jelzések miatt. Az a vélemény, hogy az a kérdés, vajon üzemeltetési szempontból elfogadható-e, vagy sem a sugárzásnak az egy keskeny szektorban való összeszűkülése miatti irányszektoron kívüli jel karakterisztika, az adott érintett helyen történő egyedi kiértékelés tárgya.

2.1.11.3.5 A 4) pontban jelzett hátsó irányszektor elvesztésének több hátránya lehet. Bizonyos helyeken, a hátsó irányszektor hasznos funkcióként szolgál a más berendezésekkel való metszéspontjai által az érintett területre meghatározott eljárások elősegítésére. Azonkívül a hátsó irányszektor gyakran hasznos segítséget biztosít a megszakított megközelítési eljárásokhoz is, és gyakran fel lehet használni azoknak a leszállásokhoz történő megközelítéseknek az egyszerűbbé tételénél, amelyeket olyan körülmények tesznek szükségessé, hogy a leszállási irány ellentétes azzal az iránnyal, amit az ILS elsődlegesen kiszolgál. A hátsó irányszektor elvesztése általában megfelelő eszköz, vagy eszközök biztosítását teszi szükségessé, és a hátsó irányszektor elnyomásának elsődleges hátrányát a helyettesítő berendezés, vagy berendezések kiegészítő költségében kifejezve is figyelembe vehető.

2.1.11.4 *Az iránysáv vonalon központosuló szektor szűkítési lehetőségének mértéke.* Az a vélemény, hogy az iránysáv vonal mindkét oldalán minimálisan 10 fokos sugárzási szektor lehet az, ami még üzemeltetési szempontból elfogadható. Az a kívánatos, hogy az iránysáv adótól származó jelek karakterisztikája megegyezzen azzal, ami a 3. Fejezetben előírásra került arra a körzetre, ami az iránysáv vonal közvetlen szomszédságában van (a 0,155-től a nulláig terjedő modulációs mélység különbség), illetve a 10 fokon kívüli érték közvetlen közelében van, úgy, hogy az ILS jelző műszer kijelzései és a csatoló egységbe betáplált jelek - ha ilyen használatos - feleljenek meg a szabványos ILS-nek minden olyan szükséges manőver esetében, ami az iránysávhoz való közelítéstől az iránysáv vonalra történő ráálláshoz szükséges.

Azonban tudatában kell lenni annak, hogy egy megnövelt futópálya hosszúságnál az iránysáv irányszektorának az a része, amelyen belül az arányos útirányvezetést biztosítani kell, szűkebb lesz, annak eredményeként, hogy az iránysáv adót a 3. Fejezet 3.1.3.7.1 pontjában előírt érzékenységre szabályozzák be. Jóllehet, az arányos útirány-vezetési jel biztosításra kerül az iránysáv vonal mindkét oldalán a 0,180 modulációs mélység különbség (DDM) szintig, mégis, a 0,150 modulációs mélység különbség (DDM) feletti szint lehet, hogy nem lesz használható az automatikus repülési rendszerek részére a ráállási manőver során anélkül, hogy a rendszert felszerelnék az olyan szektorban való működésre, amelyben minimálisan 0,180 modulációs mélység különbség van biztosítva (azaz plusz, vagy mínusz 10 fok). Előnyös, ha lehetővé teszik azt, hogy az automatikus fedélzeti rendszer fel legyen szerelve úgy, hogy a 10 foknál nagyobb irányszektoron kívüli szögnél is lehetővé tegye a befogási módot; ennek megfelelően az a kívánatos, hogy megtartsuk a minimális 0,180 értékű modulációs mélység különbséget a plusz, vagy mínusz 10 foknál szélesebb szektoron, ahol az gyakorlatilag megvalósítható.

2.1.11.5 *További lehetőségek.* Ha a fenti 2.1.11.3 pontban tárgyalt korlátozott fedésterületből és módosított jel jellemzők alkalmazásából eredő hátrányok elfogadhatatlanok, akkor lehetőségek vannak két rádió viviőfrekvencia alkalmazásával az olyan fedésterület és jel jellemzők biztosítására, amelyek fenntartják az elnyomott szektorban a szabvány ILS által nyújtott alapvető információkat, és ugyanakkor az iránysáv szaktor körüli körzetben megtartják a korlátozott fedésterületi rendszer céljait. Ennek a jóval bonyolultabb rendszernek az alkalmazására a magas többutas terjedési környezetű repülőtereken lehet szükség. A két rádió vivőfrekvenciás fedésterületről szóló kiegészítő útmutató anyag az alábbi 2.7 pontban került megadásra.

2.2 Az ILS légijármű fedélzeti vevő berendezése

Megjegyzés. - Az előírt tűréshatárok azok, amelyeket szükségesnek tartanak az üzemeltetési cél eléréséhez, és ahol megfelelő, a következő megengedett eltéréseket foglalják magukba:

a) a vonatkozó földi rendszerek azon határértékeken belüli eltéréseit, ami a 3. Fejezet 3.1 pontjában meghatározásra került;

b) a légijármű környezet változásait;

c) a mérési hibákat; és

d) a szolgáltatásnak a karbantartási periódusok közötti lecsökkenését.
Az ebben a részben használt "vevő berendezés" szó magát a vevőt, az antenná(ka)t és a légijárművön belüli csatolásokat foglalja magába.

2.2.1 *Általános rész*

2.2.1.1 Abból a célból, hogy a megfelelő és megbízható működés biztosítva legyen, a vevőnek az iránysáv vonalra (központosítás) és az iránysáv szélességre (eltérés) vonatkozó kimeneti jellemzőit olyan pontossági fokon kell tartani, ami az üzemeltetési célnak megfelel. Felhívjuk a figyelmet arra, hogy számításba kell venni azokat a változó feltételeket, amelyek befolyásolhatják ezt a pontosságot.

2.2.1.2 Továbbá, annak biztosítása céljából, hogy az ILS rendszer valamennyi felhasználója egy állandó iránysáv szélességet "kapjon", szabványosítani kell az iránysáv vevő teljes erősítési tényezőjét. Hasonlók figyelembevételét kell alkalmazni a siklópálya vevő esetében.

2.2.2 *Az iránysáv adó vevő hangfrekvenciás erősítésének beállítása*

2.2.2.1 A vevő hangfrekvenciás erősítésének olyannak kell lenni, hogy egy 1 000 mikrovoltos 20 százalékban a 90 Hz-es hanggal és 20 százalékban a 150 Hz-es hanggal modulált rádiófrekvenciás bemenő jel nulla kijelzést adjon, és egyidejűleg az egyik összetevőt 4,65 százalékkal (azaz 24,65 százalékra) növelve, és a másik összetevőt 4,65 százalékkal csökkentve (azaz 15,35 százalékra) egy 3/5 értékű arányos eltérés jöjjön létre a teljes iránysáv szélesség kijelzésnél, de 9,5 mm-nél nem kisebb a skálán mérve. Ezt az erősítés beállítást azzal a szabályos tápfeszültséggel kell elvégezni, ami a fedélzeti üzemeltetési körülmények esetén fennáll.

2.2.3 *Az iránysáv vevő berendezés központosítási tűrése*

2.2.3.1 Az I., II. és III. ILS Teljesítmény Kategóriához kapcsolódó üzemeltetési célok elérése és a légijárműveknek az akadálymentességi felületeken belüli biztonságos üzemeltetésének biztosításához a vevő berendezés központosítási hibája - az összes valószínűleg előforduló légijármű üzemeltetési környezeti feltételek mellett működve és a nulla jelet (modulációs mélység különbség) véve a földi berendezés rádiófrekvenciás modulációs jellemzői és meghatározott jellemző értékeinek tűréshatárain belül, ahogy azok a 3. Fejezet 3.1.3 pontjában előírásra kerültek, egy 90 mikrovolt/méter (mínusz 107 dBW/m^2) rádiófrekvenciás térerősségnél - 68 százalékos valószínűséggel nem haladhatja meg a következő határértékeket:

I. Kategória: a teljes iránysáv szélesség kijelzés 4,66 százaléka (0,0072 DDM);

II. Kategória: a teljes iránysáv szélesség kijelzés 2,33 százaléka (0,0036 DDM);

III. Kategória: a teljes iránysáv szélesség kijelzés 1,66 százaléka (0,00258 DDM).

Megjegyzés. - Ezeket a követelményeket nagyobb, az üzemeltetési gyakorlatban valószínűleg előforduló maximális térerősség mellett is teljesíteni kell.

2.2.4 *Iránysáv vevő iránysáv vonal eltolódás iránti érzékenységi (eltérés) tűréshatár*

2.2.4.1 Amikor a vevő hangfrekvenciás erősítése a fenti 2.2.2 pontban leírtaknak megfelelően van beállítva, és a hangfrekvenciás bemenő jel egyik modulációs hangja 4,65 százalékkal meg van növelve a névleges értékéhez viszonyítva (azaz 24,65 százalék), és egyidejűleg a másik összetevő 4,65 százalékkal van lecsökkentve (azaz 15,35 százalék) a névleges értékhez viszonyítva, akkor a kijelzett eltérési jel nem térhet el plusz, vagy mínusz 0,019 modulációs mélység különbségnél nagyobb értékkel a 90 mikrovolt/méter (mínusz 107 dBW/m^2) térerősség névleges értéktől egészen addig a maximális térerősségig, ami az üzemeltetési gyakorlatban valószínűleg előfordulhat.

Megjegyzés. - Lásd az alábbi 2.2.5 pontot a jelszintekre vonatkozóan.

2.2.5 *Az iránysáv vevő rendszer minimális jelszint érzékenysége*

2.2.5.1 Az iránysáv vevő berendezés érzékenységének olyannak kell lenni, hogy az érték nagy százalékában a vevőnek használható jelet kell kijelezni, és egy tartós állandó kijelzést kell adni a 3. Fejezet 3.1.3.3.2 pontjában meghatározott minimális térerősség (40 mikrovolt/méter, vagy mínusz 114 dBW/m^2) jelenlétében.

1. Megjegyzés. - Az a maximális jelszint, ami valószínűleg előfordul a fenti 2.2.3 és 2.2.4 pontok szerint, 500 mikrovolt. Az 5 000 mikrovolt nagyságrendű jelszintek az adó berendezés közvetlen szomszédságában fordulhatnak elő (azaz akkor, amikor a légijármű átrepüli az iránysáv adót a megszakított megközelítés során, vagy akkor, amikor az iránysáv a leszállás utáni kifutási, vagy felszállási irány-vezetésre kerül felhasználásra.)

2. Megjegyzés. - A fenti 2.2.4 és 2.2.5 pontban előadott két érzékenységi szint biztosítja:

a) azt a jóminőségű kimenő jelet, ami a megközelítés céljaira szükséges; és

b) a fedésterületi tér egyéb részeiben a berendezés üzemeltetési felhasználhatósága szempontjából is kielégítő gyengébb minőségű kimenő jelet.

3. Megjegyzés. - Az iránysáv vevő rendszernek szabályszerűen működni kell az előírt minimális térerő jelenlétében a légijármű hossztengelyének a vízszintes síkban elfoglalt irányától függetlenül akkor, amikor a légijármű 20 fokos bedöntési és 10 fokos bólintási szöggel repül.

2.2.6 *Az iránysáv irányvonal eltolódásának linearitása*

2.2.6.1 A vevő kimeneti irányvonal eltolódási jelének lényegében lineáris funkciót kell képezni a vevő bemenő jel modulációs mélység különbségével. Bármely bemeneti jelnek, ami a plusz, vagy mínusz 0,155 modulációs mélység különbség értékű tartományon felül és minden olyan rádiófrekvenciás jelszint esetében, ami az üzemeltetési gyakorlatban valószínűleg előfordulhat, az eltolódás iránti érzékenységnek nem szabad a fenti 2.2.2 pontban meghatározott névleges modulációs mélység különbség/ /eltérés aránytól plusz, vagy mínusz 20 százaléknál többel eltérni. Szintén, a plusz, vagy mínusz 0,165 modulációs mélység különbség, vagy ennél nagyobb értékű bemeneti jelnél, a kimenetnek nagyobbnak kell lenni, mint a teljes irányvonal eltolódás.

Megjegyzés. - Lásd a fenti 2.2.5 pontot a jelszintekre vonatkozóan.

2.2.7 *Az iránysáv vevő sávszélessége*

2.2.7.1 A vevő sávszélességének olyannak kell lenni, hogy a 3. Fejezet 3.1.3.2.1 pontjában meghatározott jellemzőkkel bíró csatornák vételét a megfelelő vevő tűréshatárának illeszkedő számításbavételével biztosítsa.

2.2.8 *Az iránysáv vevőnek a VOR és az iránysáv jelek iránti érzékenysége*

2.2.8.1 *A vevő felépítésének a következő környezetben kell pontos működést biztosítani*:

a) a kívánt jel a nem-kívánt azonos csatorna jelet 20 dB-el, vagy többel haladja meg;

b) egy nem-kívánt jel 50 kHz-re a kívánt jeltől 34 dB-el haladja meg a kívánt jelet. (A vevőnek a próbapadon történő ellenőrzése során ebben az első szomszédos csatorna esetben a nem-kívánt jel a kombinált földi állomás (plusz, vagy mínusz 9 kHz) és a vevő frekvencia tűrés frekvencia-tartománya fölött változó.);

c) egy nem-kívánt jel 100 kHz-re a kívánt jeltől 46 dB-el haladja meg a kívánt jelet;

d) egy nem-kívánt jel 150 kHz-re, vagy annál távolabb, 46 dB-el haladja meg a kívánt jelet.

1. Megjegyzés. - Elfogadott az, hogy nem az összes jelenlegi vevő felel meg a b) követelménynek, azonban az összes, jövőben elkészülő berendezést úgy kell tervezni, hogy kielégítse ezt a követelményt.

2. Megjegyzés. - Néhány Államban kisebb földi állomás tűréseket alkalmaznak.

2.2.9 *Az ILS vevő rendszer érzéketlenségi teljesítménye a VHF FM adások jeleinek zavaró hatásával szemben*

2.2.9.1 A 3. Fejezet 3.1.4.2 pontjának 2. megjegyzésére vonatkozóan, az ott meghatározott érzéketlenségi teljesítményt a vevő rendszer szabályos teljesítményéhez viszonyított egyezményes csökkenési mértékhez kell venni a bemenő megkívánt jel szabvány körülményei mellett és jelenlétében. Ez annak biztosításához szükséges, hogy a vevő berendezésnek a próbapadi ellenőrzését egy ismételhető feltétel-rendszer és eredmények mellett lehessen elvégezni, ami elősegítse az azt követő hitelesítési jóváhagyásukat. Vizsgálatok kimutatták azt, hogy az FM interferencia jelek hatással lehetnek mind az iránysáv irányvezetési, mind a jelölő áramra, és hatásuk annak a megkívánt jelnek a modulációs mélység különbségétől függ, amit alkalmaznak. Kiegészítő tájékoztatások találhatók a Nemzetközi Távközlési Unió /ITU/ ITU-R IS.1140 számú *A 87 - 108 MHz-es műsorszóró* *szolgáltatási sáv és a 108 - 118 MHz-es légiforgalmi szolgálati sáv közötti kompatibilitás meghatározására használatos vevők jellemzőinek ellenőrzési eljárásai* című Ajánlásában.

2.2.9.2 Általánosan elfogadott módszereket és képleteket kell alkalmazni azoknak a vevőknek a lehetséges összeférhetetlenségének megállapításához, amelyek megfelelnek a 3. Fejezet 3.1.4 pontjában meghatározott általános interferencia érzéketlenségi követelményeknek. A képleteknek tisztázniuk kell a parazita sugárzással (A1 típusú) szembeni interferencia érzéketlenségi teljesítményt, a csatorna sávon kívüli (A2 típusú) interferenciával szembeni, a két-jel és három-jel harmadrendű (B1 típusú) interferenciával szembeni és a túlterhelés / érzéketlenítés (B2 típusú) interferenciával szembeni interferencia érzéketlenségi teljesítményt. Kiegészítő tájékoztatások találhatók az ITU-R IS.1009-1 sz. *Kompatibilitás a 87 - 108 MHz-es műsorszóró szolgáltatási sáv és a 108 - 137 MHz-es légiforgalmi szolgálati sáv között* Ajánlásában.

2.2.9.3 A Nemzetközi Távközlési Unió /ITU/ ITU-R IS.1009-1 Ajánlásában megadott frekvencia tervezési követelmények nem veszik számításba a lehetséges két-jel és három-jel ötödrendű (B1 típusú) intermodulációs termékeket. Mérésekkel határozták meg azt, hogy az FM állomások által a vevőkben létrehozott ötödrendű intermodulációs termékek úgy lecsökkenthetik az ILS vevők teljesítményét, hogy az a 3. Fejezet 3.1.4 pontjában leírt meghatározásoknak felel meg. Az ötödrendű intermodulációs termékek előfordulhatnak anélkül, hogy egy harmadrendű intermodulációs termék fordulna elő ugyanazon az ILS frekvencián. A frekvenciák tervezésében és az FM műsorszóró interferenciája elleni védelem felbecsülésénél szükség van arra, hogy figyelembe vegyék a két-jel és három-jel által létrehozott ötödrendű intermodulációs termékeknek az ILS vevőkön belül létrehozott termékeit.

2.2.10 *A siklópálya vevő hangfrekvenciás erősítésének beállítása*

2.2.10.1 A vevő hangfrekvenciás erősítésének olyannak kell lenni, hogy egy 600 mikrovoltos 40 százalékban a 90 Hz-es hanggal és 40 százalékban a 150 Hz-es hanggal modulált rádiófrekvenciás bemenő jel nulla kijelzést adjon, és egyidejűleg az egyik összetevőt 5,25 százalékkal (azaz 45,25 százalékra) növelve, és a másik összetevőt 5,25 százalékkal csökkentve (azaz 34,75 százalékra) egy 3/5 értékű arányos eltérés jöjjön létre a teljes irányvonal kijelzésnél, de 9,5 mm-nél nem kisebb a skálán mérve. Ezt az erősítés beállítást azzal a szabályos tápfeszültséggel kell elvégezni, ami a fedélzeti üzemeltetési körülmények esetén fennáll.

2.2.11 *A siklópálya vevő berendezés központosítási tűrése*

2.2.11.1 Az I., II. és III. ILS-Teljesítmény Kategóriához kapcsolódó üzemeltetési célok elérése és a légijárműveknek az akadálymentességi felületeken belüli biztonságos üzemeltetésének biztosításához, a vevő berendezés központosítási hibája az összes valószínűleg előforduló légijármű üzemeltetési környezeti feltételek mellett működve, és a nulla jelet (modulációs mélység különbség) véve, a földi berendezés rádiófrekvenciás modulációs jellemzői és meghatározott jellemző értékeinek tűréshatárain belül, ahogy azok a 3. Fejezet 3.1.5 pontjában előírásra kerültek, és egy 400 mikrovolt/méter (mínusz 95 dBW/m^2) rádiófrekvenciás térerősséget egy 68 százalékos valószínűséggel nem haladhatja meg a következő határértékeket:

I. kategória: a teljes irányvonal szélesség kijelzés 5,33 százaléka (0,0093 DDM);

II. kategória: a teljes irányvonal szélesség kijelzés 3,33 százaléka (0,0058 DDM);

III. kategória: a teljes irányvonal szélesség kijelzés 3,33 százaléka (0,0058 DDM).

Megjegyzés. - Ezeket a követelményeket nagyobb, az üzemeltetési gyakorlatban valószínűleg előforduló maximális térerősség mellett is teljesíteni kell.

2.2.12 *Siklópálya irányvonal eltolódás iránti érzékenységi (eltérés) tűréshatár*

2.2.12.1 Amikor a vevő hangfrekvenciás erősítése a fenti 2.2.9 pontban leírtaknak megfelelően van beállítva, és a hangfrekvenciás bemenő jel egyik modulációs hangja 5,25 százalékkal meg van növelve a névleges értékhez viszonyítva (azaz 45,25 százalék), és egyidejűleg a másik összetevő 5,25 százalékkal van lecsökkentve (azaz 34,75 százalék) a névleges értékhez viszonyítva, akkor a kijelzett eltérési jel nem térhet el plusz, vagy mínusz 0,016 modulációs mélység különbségnél nagyobb értékkel a 400 mikrovolt/méter (mínusz 95 dBW/m^2) térerősség névleges értékhez viszonyítva, egészen addig a maximális térerősségig, ami az üzemeltetési gyakorlatban valószínűleg előfordulhat.

Megjegyzés. - Lásd az alábbi 2.2.13 pontot a jelszintekre vonatkozóan.

2.2.13 *A siklópálya vevő rendszer minimális jelszint érzékenysége*

2.2.13.1 A siklópálya vevő berendezés érzékenységének olyannak kell lenni, hogy az érték nagy százalékában a vevőnek használható jelet kell kijelezni, és egy tartós állandó kijelzést kell adni a 3. Fejezet 3.1.5.3.2 pontjában meghatározott minimális térerősség (400 mikrovolt/méter, vagy mínusz 95 dBW/m^2) jelenlétében.

1. Megjegyzés. - Az a maximális jelszint, ami valószínűleg előfordul a fenti 2.2.11 és 2.2.12 pontok szerint, 2 500 mikrovolt. Ez a jelszint akkor fordul elő, amikor a légijármű a futópálya küszöbe fölött van.

2. Megjegyzés. - A fenti 2.2.12 és 2.2.13 pontban előadott két érzékenységi szint biztosítja:

a) azt a jóminőségű kimenő jelet, ami a megközelítés céljaira szükséges; és

b) a fedésterületi tér egyéb részeiben a berendezés üzemeltetési felhasználhatósága szempontjából is kielégítő gyengébb minőségű kimenő jelet.

3. Megjegyzés. - A siklópálya vevő rendszernek szabályszerűen működni kell az előírt minimális térerő jelenlétében akkor is, ha a légijármű hossztengelye a vízszintes síkban plusz, vagy mínusz 10 fokkal eltér, és ugyanakkor a bedöntése 20 fokos az iránysáv adó iránysáv vonala síkjában és a bólintása is plusz, vagy mínusz 10 fokos a vízszintes síkhoz viszonyított függőleges síkban.

2.2.14 *A siklópálya eltolódásának linearitása*

2.2.14.1 A vevő kimeneti siklópálya eltolódási jelének lényegében lineáris funkciót kell képezni a vevő bemenő jel modulációs mélység különbségével. Bármely bemeneti jelnek, ami a plusz, vagy mínusz 0,175 modulációs mélység különbség értékű tartományon felül és minden olyan rádiófrekvenciás jelszint esetében, ami az üzemeltetési gyakorlatban valószínűleg előfordulhat, az eltolódás iránti érzékenységnek nem szabad a fenti 2.2.10 pontban meghatározott névleges modulációs mélység különbség / eltérés aránytól plusz, vagy mínusz 20 százaléknál többel eltérni.
Egy 0,185, vagy annál nagyobb modulációs mélység különbségű bemenő jel esetén a kimenetnek nagyobbnak kell lenni, mint a teljes teljes irányvonal eltolódás.

Megjegyzés. - Lásd a fenti 2.2.13 pontot a jelszintekre vonatkozóan.

2.2.15 *A siklópálya vevő sávszélessége*

2.2.15.1 A vevő sávszélességének olyannak kell lenni, hogy a 3. Fejezet 3.1.5.2.1 pontjában meghatározott jellemzőkkel bíró csatornák vételét a megfelelő vevő tűréshatárának illeszkedő számításbavételével biztosítsa.

2.2.16 *A siklópálya vevőnek a siklópálya jelek iránti érzékenysége*

2.2.16.1 A vevő felépítésének a következő környezetben kell pontos működést biztosítani:

a) a kívánt jel a nem-kívánt azonos csatorna jelet 20 dB-el, vagy többel haladja meg;

b) egy nem-kívánt siklópálya jel 150 kHz-re a kívánt jeltől 20 dB-el haladja meg a kívánt jelet. (A vevőnek a próbapadon történő ellenőrzése során ebben az első szomszédos csatorna esetben a nem-kívánt jel a kombinált földi állomás (plusz, vagy mínusz 17 kHz) és a vevő frekvencia tűrés frekvencia-tartománya fölött változó.);

c) egy nem-kívánt siklópálya jel a kívánt jeltől 300 kHz-re, vagy annál távolabb 40 dB-el haladja meg a kívánt jelet.

1. Megjegyzés. - Elfogadott az, hogy nem az összes jelenlegi vevő felel meg a b) követelménynek, azonban az összes, jövőben elkészülő berendezést úgy kell tervezni, hogy kielégítse ezt a követelményt.

2. Megjegyzés. - Néhány Államban kisebb földi állomás tűréseket alkalmaznak.

2.2.17 *A függőleges polarizáció hatása az iránysáv és siklópálya vevőre*

2.2.17.1 Az iránysáv és siklópálya frekvencia-tartományban, külön-külön az iránysáv és a siklópálya antennára vonatkozó előre ható irányú, függőlegesen polarizált jelek vétele legalább 10 dB-el alatta kell legyen az ugyanabból az irányból eredő vízszintesen polarizált jelek vételének.

2.2.18 *Az iránysáv és a siklópálya vevő téves jelvétele*

2.2.18.1 Az iránysáv vevőnek egy 150 Hz-es 30 százalékig modulált rádiófrekvenciás jelre a 110 MHz-nél történő reagálásának (kijelző műszer eltérés) nagyobbnak kell lenni azon rádiófrekvenciás jelre történő reagálásánál, mint amit az azonosan modulált, de 60 dB-el nagyobb amplitudójú és a 90 kHz-től a 107,8 MHz-ig, valamint a 112,2 MHz-től az 1 500 MHz-ig változtatott jelekre ad. A siklópálya vevőnek egy 150 Hz-es 30 százalékig modulált rádiófrekvenciás jelre a 332,0 MHz-nél történő reagálásának (kijelző műszer eltérés) nagyobbnak kell lenni azon rádiófrekvenciás jelre történő reagálásánál, mint amit az azonosan modulált, de 60 dB-el nagyobb amplitudójú és a 90 kHz-től a 329,0 MHz-ig, valamint a 335,3 MHz-től az 1 500 MHz-ig változtatott jelekre ad.

2.3 Működési hiba riasztás az ILS fedélzeti rendszerben

2.3.1 Ideálisan a vevő riasztó rendszerének egy olyan eszközzel, mint a vizuális mechanikus zászló, kell figyelmeztetnie a légijármű vezetőjét bármilyen olyan elfogadhatatlan működési hiba állapotra, amely mindkét, vagy a földi, vagy a fedélzeti berendezéseken belül keletkezhet. Annak a mértéke, hogy egy ilyen ideál meddig elégíthető ki, az alábbiakban kerül meghatározásra.

2.3.2 A riasztó rendszert a két modulációs mélység összege hozza működésbe, és ennek megfelelően az ILS iránysáv modulációs összetevőinek a kisugárzott vivőfrekvenciáról való kimaradása a riasztás működésbe léptetését eredményezi.

2.3.3 A riasztó rendszernek jelezni kell a légijárművezető és az összes többi olyan fedélzeti rendszer részére, amelyek az iránysáv és a siklópálya adatokat felhasználják, a következő helyzetek bármelyikének fennállását:

a) bármilyen rádiófrekvenciás jel hiányát, valamint az egyidejű 90 Hz-es és 150 Hz-es moduláció hiányát;

b) bármelyik, a 90 Hz-es, vagy a 150 Hz-es jel modulációs mélységének a nullára csökkenését, úgy, hogy a másik megtartja a szabályos 20 százalékos és 40 százalékos modulációját külön-külön az iránysávra és a siklópályára;

Megjegyzés. - Az az elvárt, hogy az iránysáv riasztás akkor történjen meg, amikor bármelyik, vagy a 90 Hz-es, vagy a 150 Hz-es moduláció 10 százalékra lecsökken úgy, hogy a másik megtartja a szabályos értéke 20 százalékát. Az az elvárt, hogy a siklópálya riasztás akkor történjen meg, amikor bármelyik, vagy a 90 Hz-es, vagy a 150 Hz-es moduláció 20 százalékra lecsökken úgy, hogy a másik megtartja a szabályos értéke 40 százalékát.

c) a vevő útiránytól való eltérés jelzése 50 százaléka, vagy annál kisebb értékű ahhoz viszonyítva, ami a vevő hangfrekvenciás erősítési beállításának (lásd a fenti 2.2.2 és 2.2.10 pontokat) a beállítására meghatározásra került.

2.2.3.1 A riasztási jelzésnek könnyen észrevehetőnek és jól láthatónak kell lenni minden szabályszerű pilótakabinon belüli körülmény esetén. Ha egy zászlót használnak, akkor annak a kijelző műszerhez mérten olyan nagynak kell lenni, amennyire csak lehetséges.

2.4 A siklópálya adó berendezés telepítésére, magasságára, beállítására és fedésterületére vonatkozó útmutatások

2.4.1 Az ILS vonatkozási alap és az ILS siklópálya szögének beállítása adják azokat az elsődleges tényezőket, amelyek az ILS siklópálya berendezésnek a futópálya küszöbéhez viszonyított hosszirányú elhelyezését befolyásolják.

2.4.2 A siklópálya antenna-rendszernek a futópálya középvonalához viszonyított oldalirányú elhelyezése általában nem lehet kevesebb 120 méternél (400 láb). A siklópálya antenna oldalirányú elhelyezésének az eldöntésénél számításba kell venni az Annex 14-nek az akadálymentességi felületekre és a futópálya sávokon elhelyezett akadályokra vonatkozó előírásait.

2.4.3 Az ILS siklópálya antenna elhelyezésének és a siklópálya szögének kiválasztásánál a célnak annak kell lennie, hogy az ILS vonatkozási pontot a megfelelő névleges értékhez olyan közel tegyék, amennyire az csak lehetséges. Az ILS siklópálya antenna helyének és a siklópálya szögének tényleges kiválasztását számos tényező befolyásolja, beleértve a(z):

a) adott repülőtéren tervezett üzemeltetési típusok elfogadható süllyedési mértékét és/vagy megközelítési sebességét;

b) repülőtér körzetében, a végső megközelítési területen és a megszakított megközelítési területen lévő akadályok helyzetét és az azokból eredő akadálymentességi korlátozásokat;

c) technikai telepítési problémákat.

2.4.4 Az antenna elhelyezése és a siklópálya szög kiválasztását, valamint a kialakuló ILS vonatkozási pont magasságot befolyásolni fogja még:

a) a rendelkezésre álló futópálya hosszúsága;

b) az előre látott üzemeltetési korlátok.

Ahol az előbb említett követelmények alkalmazása lehetővé teszi, ott az ILS siklópálya előnyben részesített szögének 3 foknak kell lenni.

2.4.5 Ezután az ILS vonatkozási pontot és a siklópályát kell megválasztani az alábbiakban említett követelmények figyelembevételével, majd a hely alkalmasságot kell megvizsgálni, hogy biztosítja-e a *Léginavigációs Szolgálatok Eljárásai - Légijármű Üzemeltetések* (PANS-OPS, Doc 8168) által megkövetelt akadálymentességet és a telepítési helyet számításokkal és - ahol lehetséges - légi ellenőrzéssel kell megerősíteni.

2.4.6 Ahol a kiválasztott ILS vonatkozási pont, az ILS siklópálya szöge és az egyéb vonatkozó berendezés jellemzők nem biztosítják a szükséges akadálymentességet, ott a következő alternatív megoldásokat kell megvizsgálni:

1) a zavaró akadály eltávolítása;

2) egy másik magasság kiválasztása az ILS vonatkozási pontra, figyelembe véve a fenti 2.4.3 és 2.4.5 pontokban jelzett követelményeket;

3) egy másik elfogadható ILS siklópálya szög kiválasztása;

4) az akadálymentességi határok módosítása úgy, hogy a zavaró akadálynak megfeleljenek.

2.4.7 A III. Kategóriájú ILS siklópályaadó telepítési helyének szomszédságában lévő terep jóval hatékonyabb felhasználása lehetővé tételének céljából és azért, hogy ezeken a helyeken a telepítési követelményeket és az érzékenységi területeket csökkentsék, az a kívánatos, hogy a III. Kategóriájú ILS siklópálya antenna rendszer vízszintes sugárzási karakterisztikáját kialakító jeleket olyan alacsony értékűre csökkentsék, amennyire az csak lehetséges, a 3. Fejezet 3.1.5.3 pontjában meghatározott oldalszög fedésterületi határértékeken kívül. Egy másik elfogadható módszer az, hogy oldalszögben elfordítsák a siklópálya antennákat a többutas terjedési forrásoktól és ezáltal meghatározott szögekben csökkentsék a kisugárzott jelek mennyiségét úgy, hogy körben fenntartják az oldalszögbeli fedésterület határvonalait.

2.4.8 *Az ILS siklópálya görbülete*. A legtöbb esetben az ILS siklópályát a siklópálya antenna-rendszerétől kiinduló kúpos felület alkotja. Ennek a kúpfelületnek a kiindulási pontjának a futópálya középvonalától való oldalirányú kihelyezése következtében, a siklópálya geometriai helye a futópálya középvonala mentén lévő függőleges síkban egy hiperbola. A siklópálya görbülete a küszöb körzetében jelenik meg, és fokozatosan növekszik a földetérési pontig.

2.4.9 A siklópálya antenna telepítési helye és a siklópálya irányvonalnak a küszöb feletti keresztezési magassága közötti összefüggés. A siklópálya antenna hosszirányú elhelyezését úgy kell kiválasztani, hogy az megfeleljen a 3. Fejezet 3.1.5.1.4 pontjában megadott ajánlásoknak, az ILS vonatkozási pontnak a futópálya küszöbe feletti magasságára vonatkozóan. Az ILS vonatkozási pontnak a futópálya küszöbe feletti magassága ezután a siklópálya antenna hosszirányú helyzetének, a siklópálya reflexiós síkja hosszirányú lejtésének és a futópálya küszöbének a siklópálya reflexiós síkjához viszonyított helyzetének a függvénye lesz. Ezt a helyzetet adja meg képi formában a C-5. számú ábra. A siklópálya antenna hosszirányú helyzete ezután a következők szerint számítható ki:

$$D = \frac{H + Y}{\tan(\theta + \alpha)}$$

ahol:
D = az O és P közötti vízszintes távolság;

H = a névleges küszöb keresztezési magasság;

Y = a futópálya küszöbnek a P' pont feletti függőleges magassága;

θ = a névleges ILS siklópálya szög;

α = a siklópálya reflexiós síkjának a hosszirányú lejtése.

Megjegyzés. - A fenti egyenletben az α-t pozitív értékűnek kell venni az antennától a küszöb felé való lejtés esetében. Az Y-t pozitívnak kell venni akkor, ha a küszöb a reflexiós sík keresztezési vonala felett van.

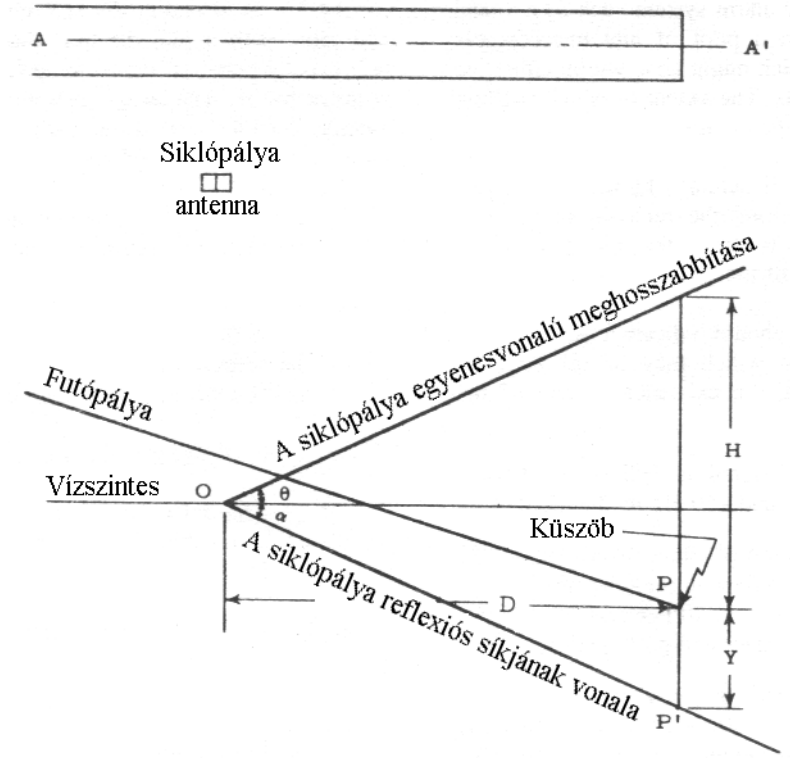
2.4.10 A siklópálya antennának a futópálya küszöbéhez viszonyított hosszirányú elhelyezésére vonatkozó, az előzőekben megadott útmutató anyag, ami figyelembe veszi azt a tényt, hogy a futópálya lehet, hogy nincs a siklópálya reflexiós síkjában, és azt, hogy a siklópálya reflexiós síkja lejtős lehet, geometriai absztrakción alapszik. Az anyag magától értetődően elfogadja azt, hogy a siklópálya elhelyezkedése a futópálya középvonalát magába foglaló függőleges síkban egy tökéletes hiperbola; következésképpen a siklópálya meghosszabbítása magától értetődően elfogadva ennek a hiperbolának a fő-érintője.
2.4.11 Valójában azonban, a siklópálya gyakran egészen szabálytalan. A közepes ILS siklópálya szög csak kalibráló repülésekkel állapítható meg; a siklópálya A- és B-pontja közötti azon rész átlagos észlelt helyzetet egy egyenes vonalként ábrázolják, és az ILS siklópálya szöge az a szög, amit az egyenes vonal és annak a vízszintes síkra való függőleges vetülete között mérnek.

2.4.12 Fontos annak elismerése, hogy a siklópálya egyenetlenségeinek hatását, ha a középső helyjeladó és a küszöb közötti körzeten belül átlagolják, akkor az valószínűleg egy olyan vonatkozási pontot vetít ki, amely ténylegesen különbözik az ILS vonatkozási ponttól. Ezt a vonatkozási pontot, amelyet itt, mint elért ILS vonatkozási pontot határoztunk meg, fontos üzemeltetési jellegűnek kell tekinteni, és el kell fogadni. Az elért ILS vonatkozási pontot csak légi ellenőrzéssel lehet megállapítani, azaz a siklópálya azon részének átlagos észlelt helyzetét, ami jellemzően a futópálya küszöbétől az 1 830 méteres (6 000 láb) és a 300 méteres (1 000 láb) távolságú pontok között van, egy egyenes vonalként tűntetik fel, és meghosszabbítják a földetérési pontig. Az a pont, ahol ez a meghosszabbított egyenes vonal "találkozik" a futópálya középvonalának a küszöbön keresztül megrajzolt függőleges vonalával, az elért ILS vonatkozási pont.

Megjegyzés. - A siklópálya szög és az elért ILS vonatkozási pont mérésére vonatkozó további útmutató anyagot a Doc 8071 adja meg.

2.4.13 A 3. Fejezet 3.1.5.3.1 pontja az egy jellemző légijármű fedélzeti berendezés kielégítő működését biztosító siklópálya fedésterületet mutatja be. Az egy berendezésre közzétett üzemeltetési eljárásoknak összeegyeztethetőknek kell lenniük a fedésterület alsó határával. Ez rendszerint a befogási magasságra végrehajtott süllyedéseket és az ezen a magasságon folytatott megközelítést jelenti addig, amíg a "süllyedj" jelzés vételre nem kerül. Bizonyos körülmények között a helyzet kereszt-ellenőrzése ennél a pontnál nem állhat rendelkezésre. Az automatikus repülés vezérlő rendszerek általában akkor kezdik meg a süllyedést, amikor az "emelkedj" jel 10 mikroampernél kisebb értékűre csökken.

2.4.14 Ennek megfelelően a cél az, hogy egy emelkedj jelzést biztosítsanak a siklópályára történő ráállást megelőzően. Jóllehet, szabvány körülmények esetén a megközelítési eljárások úgy kerülnek végrehajtásra, hogy a siklópálya jeleket nem használják fel a 0,45 θ alatt, vagy a futópályától 18,5 km-en (10 tengeri mérföld) kívül, az a kívánatos, hogy félrevezető irányvezetési tájékoztatás ne kerüljön erre a területre kisugárzásra. Ahol az eljárások olyanok, hogy a siklópálya irányvezetést lehet, hogy a 0,45 θ alatt is felhasználják, ott kielégítő óvintézkedéseket kell tenni a 0,45 θ alatti félrevezető irányvezetési információk kisugárzása elkerülésére, mind a szabályos körülmények, mind a működési hiba során, hogy ezáltal megakadályozzák azt, hogy a végső megközelítési süllyedés a megközelítésnek egy pontatlan pontján kezdődjön meg. A félrevezető irányvezetés kisugárzása ellen alkalmazható ilyen óvintézkedések magukba foglalhatják az olyan kiegészítő biztonsági-vezetési jelek kisugárzását, mint ami a 3. Fejezet 3.1.5.2.1 pontjában megadásra került, egy különálló kiegészítő biztonsági jel, felügyelő rendszer és a megfelelő földi ellenőrzés, valamint a beállítási eljárások ellenőrzésének biztosításával.



AA' METSZET NÉZET

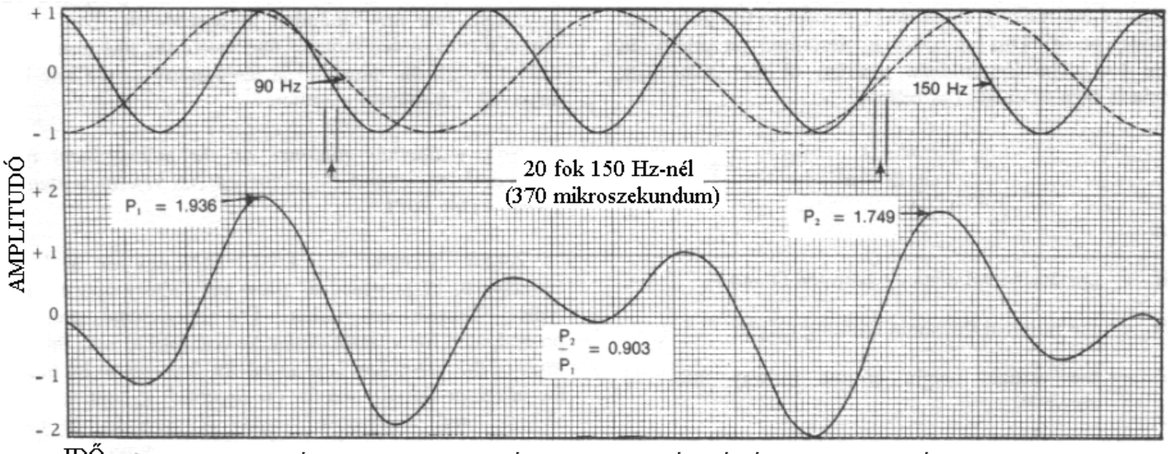
Megjegyzés. - Az OP' egyenes a siklópálya reflexiós síkjának és az AA' vonalon átmenő függőleges síknak a metszését jelenti.

C-5. ábra: A siklópálya elhelyezése lejtős futópálya esetében

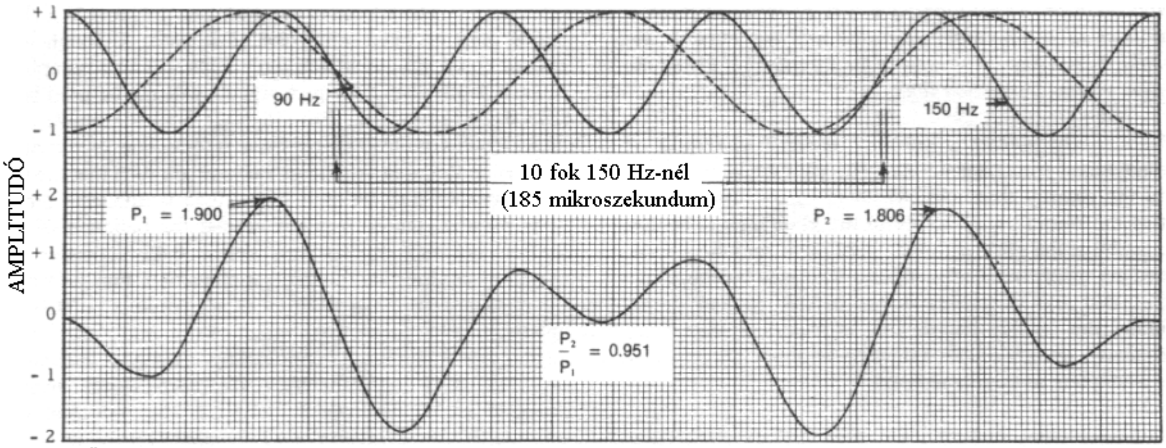
2.4.15 Ahhoz, hogy kielégítő felügyelő rendszer védelmet érjenek el, a siklópálya alatti tűréshatáron kívüli modulációs mélység különbség ellen, az alkalmazott antenna-rendszertől függően a 3. Fejezet 3.1.5.7.1 e) pontjában előírtaknak megfelelő eltolódás érzékenységi felügyelő rendszer lehet, hogy nem lesz kielégítő ahhoz, hogy a kiegészítő biztonsági-vezetés ellenőrzésére is szolgáljon. Bizonyos rendszerekben, például azoknál, amelyek többelemes antennát alkalmaznak kiegészítő biztonsági-vezetés nélkül, bizonyos antenna jelek kismértékű csökkenése komoly csökkenést tud előidézni a biztonsági-vezetési jelnél anélkül, hogy változás történne, vagy úgy, hogy csak jelentéktelen változást érzékel a siklópálya szektoron belül az eltérés érzékelő felügyelő rendszer. Ezért fontos annak biztosítása, hogy a felügyelő rendszer riasztását bármilyen, vagy az összes lehetséges olyan rosszabbodó antenna és kisugárzott jel körülménye esetére valósítsák meg, ami a biztonsági-vezetési jelnek a 0,175, vagy annál kisebb értékű modulációs mélység különbség csökkenéséhez vezet a siklópálya alatti biztonsági-vezetési jel fedésterületen.

2.5 Szemléltető ábrák

(A C-6.-tól a C-12.-ig terjedő ábrák a 3. Fejezetben tárgyalt bizonyos szabványokat szemléltetik.)



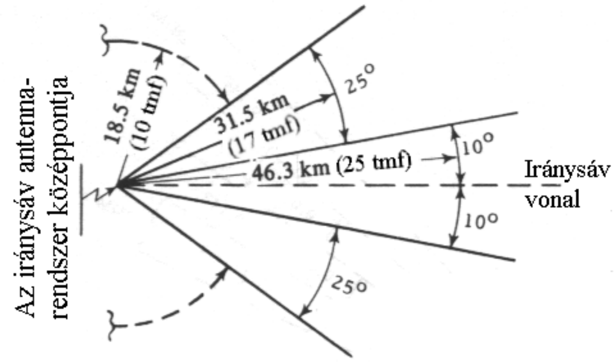
I. ÉS II. TELJESíTMÉNY KATEGÓRIÁJÚ BERENDEZÉS
IRÁNYSÁV ÉS SIKLÓPÁLYA



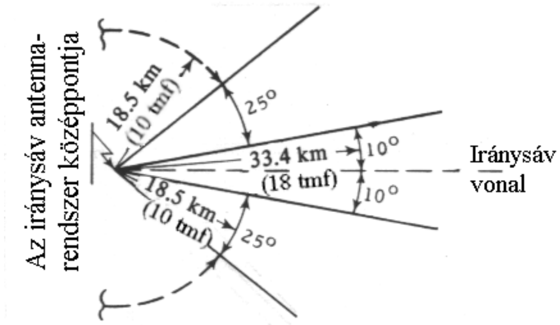
III. TELJESíTMÉNY KATEGÓRIÁJÚ BERENDEZÉS
IRÁNYSÁV ÉS SIKLÓPÁLYA

A mellékelt grafikonok azt a módszert mutatják be, amit fel lehet használni a 90 Hz-es és a 150 Hz-es hangok közötti relatív fázisszabály mérésére. Az egyes ábrák felső része az egyedi hullámokat és annak fázisszabályát mutatja be a 3. Fejezet 3.1.3.5.3.3 és 3.1.5.5.3 pontjaiban megengedett fáziskülönbségek határán. Az alsó rész azt az összetett hullámalakot mutatja be, amit egy oszcilloszkópon látni lehet. A P_1 és P_2 arányt véve, ami megadja az egységgel egyenlő, vagy annál kisebb értéket, meg lehet határozni azt, hogy a fázis a tűrésértéken belül van-e. Az ILS I. és II. Kategóriára az aránynak 0,903-nél nagyobbnak kell lenni, és a III. Kategóriára az arány 0,951-nél nagyobb kell, hogy legyen.

C-6. ábra: A 90 Hz-es és a 150 Hz-es hangok relatív hangfrekvenciás fázis helyzetét bemutató ILS hullámformák

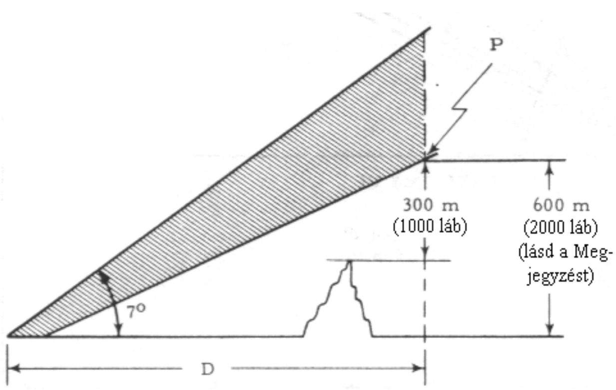


Amikor a terepviszonyok megkövetelik, vagy az üzemeltetési körülmények és az alternatív navigációs berendezések lehetővé teszik, akkor a következő fedésterületet lehet biztosítani:



Megjegyzés. - Ha a fedésterület a 3. Fejezet 3.1.3.3.1 pontjában leírtaknak megfelelően a plusz, vagy mínusz 35 fokos szektoron kívül is szükséges, akkor ez 18,5 km-ig (10 tengeri mérföld) kerül biztosításra, úgy, ahogy azt a fenti szaggatott vonalú körív jelzi.

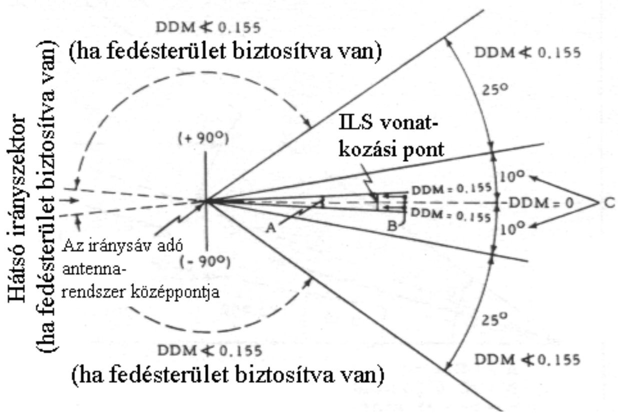
C-7. ábra: Az iránysáv oldalszögre vonatkozó fedésterülete



D = A távolságok és oldalszögek a 3.1.3.3.1 pontban kerültek meghatározásra.

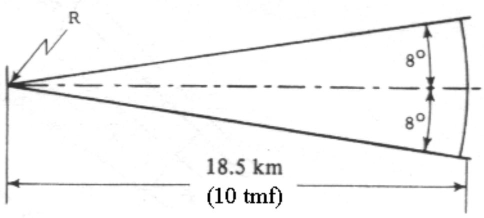
Megjegyzés. - A P-pont vagy 600 méterrel (2 000 láb) van a küszöb tengerszinthez viszonyított magassága felett, vagy 300 méterrel (1 000 láb) a közbenső, vagy a végső megközelítési területen belül lévő legmagasabb pont tengerszinthez viszonyított magassága felett, amelyik a magasabb.

C-8. ábra: Az iránysávnak a magassági szögre vonatkozó fedésterülete

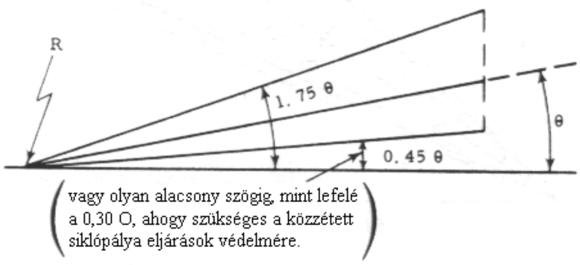


A - Iránysáv szektor > 6 fok
B - Eltolódási érzékenység = 0,00145 DDM/m (0,00044 DDM/láb) az ILS vonatkozási pontnál.
C - A modulációs mélység különbség lineáris a nullától a 0,180 értékig és azután < 0,180

C-9. ábra: A modulációs mélység különbség és az eltolódási érzékenység



(a) Oldalszögbeli fedés

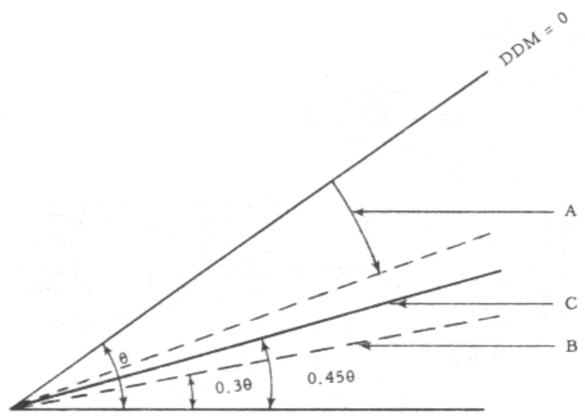


(b) Magassági szög fedés

R = Az a pont, amelynél az ILS siklópálya lefelé meghosszabbított egyenes része metszi a futópálya középvonalát.

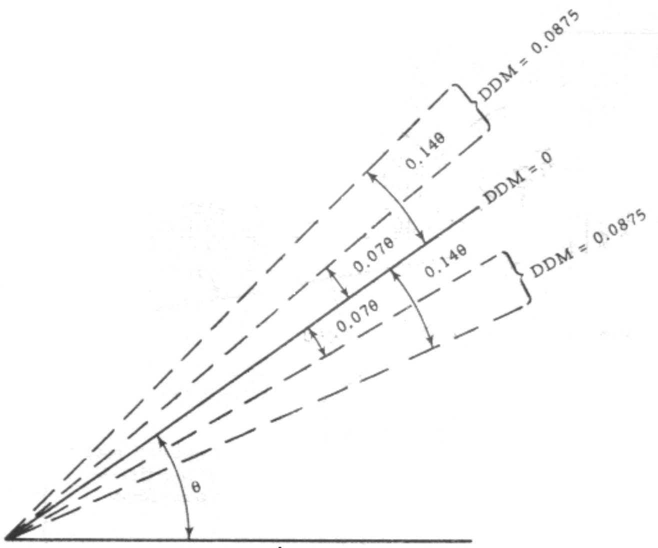
θ = az (ILS) siklópálya szög 2° és 4° között állítható be.

C-10. ábra: Siklópálya fedésterület



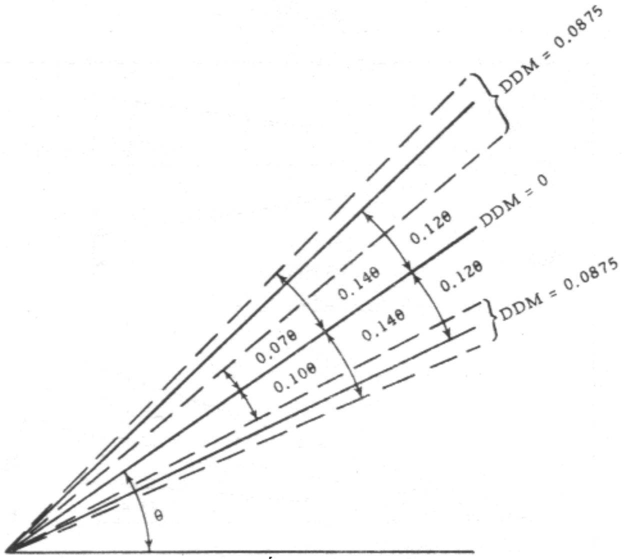
A - a DDM egyenletesen növekszik 0,22 DDM-ig
B - < 0,22 DDM lefelé a 0,3 θ-ig
C - Ha a DDM-et elérik bármilyen, a 0,45 θ feletti szögnél, akkor a DDM értéke nem lehet kevesebb 0,22-nél lefelé, legalább a 0,45 θ -ig, vagy olyan alacsony szögig, mint lefelé a 0,30 θ, ahogy szükséges a közzétett siklópálya befogási eljárás védelmére.

DDM jellemzők a siklópálya alatt
(Minden kategóriára)

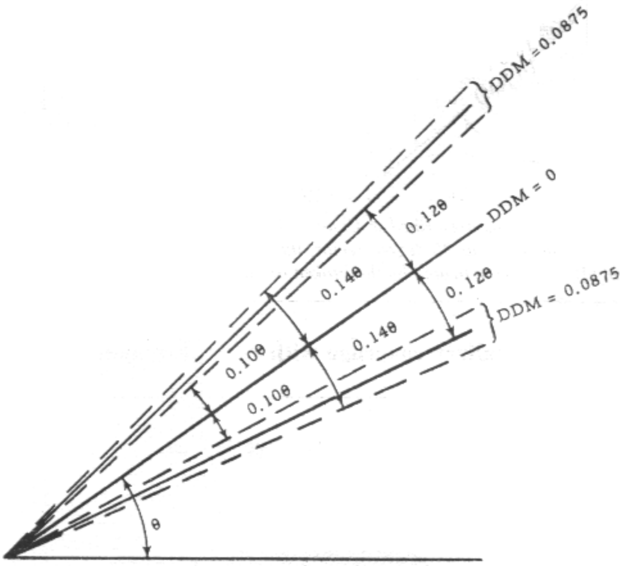


I. KATEGÓRIA

C-11. ábra: Siklópálya - modulációs mélység különbség (1. rész)



II. KATEGÓRIA

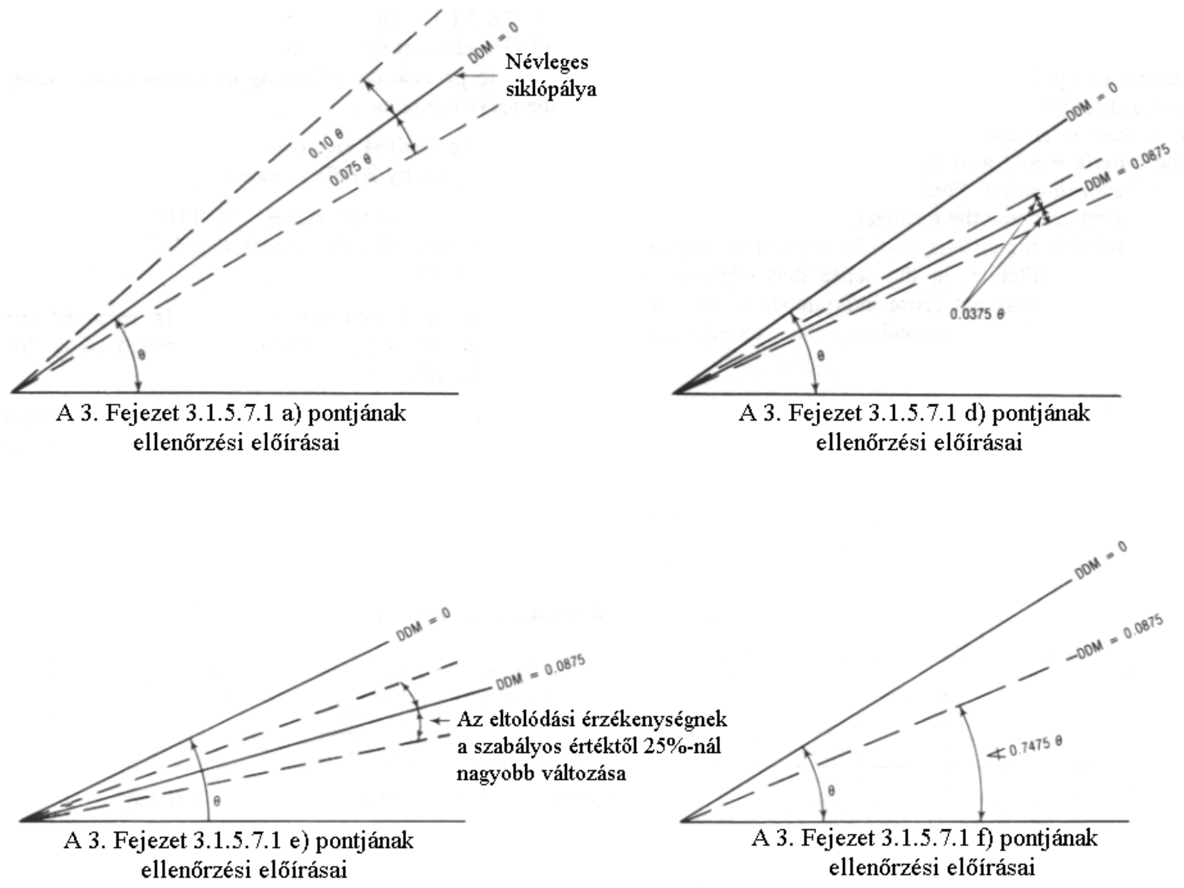


III. KATEGÓRIA

θ = Névleges siklópálya magassági szög - 2^{o} és 4^{o} között állítható be.
(A szaggatott vonal azokat a határértékeket mutatja, amelyek között a 0,0875 modulációs mélység különbséget az I., II. és III. Kategóriánál meg kell választani.)

Megjegyzés. - A C-11. ábra azokat a tűréshatárokat tűnteti fel a kisugárzott térbeli karakterisztikára, amelyek a 3. Fejezet 3.1.5.6 pontjában előírásra kerültek, azonban ezt a térberli karakterisztikát nem szabad úgy értelmezni, mint bármely meghatározott földi berendezésre jellemzőt. Ebben az összefüggésben meg kell jegyezni azt, hogy több olyan ismert típusú ILS siklópálya földi berendezés van, amelynek eltérőek a jellemzői, de amely ki tudja elégíteni a 3. Fejezet 3.1.5.6 pontjának követelményeit. Ennek megfelelően mindenütt, ahol fennáll az a követelmény, hogy ismeni kell az egy adott berendezésre vonatkozó alkalmazható tűréshatárokat, ott a referenciát a gyártó cég technikai adataiból kell megszerezni, és nem az ICAO rendszer előírásaiból.

C-11. ábra: Siklópálya - modulációs mélység különbség (2. rész)



Megjegyzés. - A szaggatott vonalak az eltolódásnak azt a megengedhető határértékét jelentik, amely előtt a felügyelő rendszer riasztási tevékenységére szükség van.

C-12. ábra: Siklópálya ellenőrzési előírások

2.6 Az ILS frekvenciák telepítési elosztása

2.6.1 A C-1. táblázatban felsorolt számok alkalmazásánál meg kell jegyezni azt, hogy ezek a zavarmentesség biztosítására vonatkoznak, a védett magasság egy pontjára és az ILS első sugárnyalábjának az irányában a szolgáltatási távolság határára. Ha fennáll a hátsó irány-szektor alkalmazásának üzemeltetési követelménye, akkor a követelményt a hátsó irányszektor megegyező pontjáig is alkalmazni kell. Ennek megfelelően az iránysáv oldalszögbeli irányítottságának figyelembevételével frekvencia tervezésre lesz szükség. Meg kell jegyezni azt, hogy a követelményt minden egyes iránysáv adó telepítésre vonatkozóan alkalmazni kell, olyan értelemben, hogy ahol két iránysáv adó van, ott lehetséges az, hogy az első nem zavarja a második használatát, és ennek ellenére a második zavart okozhat az első felhasználásában.

2.6.2 A C-1. táblázatban felsorolt számok egy olyan környezet biztosításán alapulnak, amelyen belül a fedélzeti vevő berendezések pontosan működhetnek.

C-1. táblázat: A szükséges távolsági elkülönítés

	Frekvencia távolság	A második berendezés és az első berendezés védettségi pontja közötti minimális elkülönítés km (tmf)		
		A-jegyzék	B-jegyzék	C-jegyzék
Iránysáv	Közös csatorna	148 (80)	148 (80)	148 (80)
	50 kHz	-	37 (20)	9 (5)
	100 kHz	65 (35)	9 (5)	0
	150 kHz	-	0	0
	200 kHz	11 (6)	0	0
Siklópálya	Közös csatorna	93 (50)	93 (50)	93 (50)
	150 kHz	-	20 (11)	2 (1)
	300 kHz	46 (25)	2 (1)	0
	450 kHz	-	0	0
	600 kHz	9 (5)	0	0

Az A-jegyzék olyan iránysáv vevők alkalmazására vonatkozik, amelyek 200 kHz-es csatorna elosztással és csatoltan 600 kHz-es csatorna elosztású siklópálya vevőkkel való működésre tervezettek, és csak olyan körzetekben alkalmazhatók, ahol a telepített berendezések "sűrűsége" kicsi.
A B-jegyzék olyan iránysáv vevők alkalmazására vonatkozik, amelyek 100 kHz-es csatorna elosztással és csatoltan 300 kHz-es csatorna elosztású siklópálya vevőkkel való működésre tervezettek.
A C-jegyzék olyan iránysáv vevők alkalmazására vonatkozik, amelyek 50 kHz-es csatorna elosztással és csatoltan 150 kHz-es csatorna elosztású siklópálya vevőkkel való működésre tervezettek.

1. Megjegyzés. - A fenti számjegyek a következő védettségi pontok alapfeltételként való elfogadására alapozottak: az iránysávra a 46 km-es (25 tengeri mérföld) távolságnál és 1900 m-es (6 250 láb) magasságnál, az ILS siklópályára pedig a 18,5 km-es (10 tengeri mérföld) távolságnál és 760 m-es (2 500 láb) magasságnál.

2. Megjegyzés. - Azoknak az Államoknak, amelyek a táblázatban bemutatott elkülönítéseket alkalmazzák, el kell fogadniuk annak szükségességét, hogy az ILS és VOR berendezéseket olymódon telepítik, ami eleve kizárja a légijármű fedélzeti vevőknek a nagy nem-kívánt jel szintek miatti túlterhelődési hibáját akkor, amikor a légijárművek a kezdeti és végső megközelítési szakaszokban repülnek.

3. Megjegyzés. - Azoknak az Államoknak, amelyek a táblázatban bemutatott elkülönítéseket alkalmazzák, el kell fogadniuk annak szükségességét, hogy az ILS siklópálya berendezéseket olyan módon telepítik, ami eleve kizárja a téves siklópálya kijelzéseknek a szomszédos csatorna jelek vétele miatti lehetőséget akkor, amikor a kívánt jelek sugárzása bármilyen okból megszűnik akkor, amikor a légijármű a végső megközelítési szakaszban van.

2.6.2.1 *ILS iránysáv vevők*

2.6.2.1.1 Abból a célból, hogy az 50 kHz-es csatorna elosztásra tervezett vevőknek védelmet biztosítsanak, megválasztásra kerültek azok a minimális elkülönítések, amelyek a következő minimális jel arányokat a szolgáltatási térben biztosítják:

a) a megkívánt jel az egy nem-kívánt közös csatorna jelet 20 dB-el, vagy többel haladja meg;

b) a nem-kívánt jel a megkívánt jeltől 50 kHz távolságban a megkívánt jelet 34 dB-el haladja meg;

c) a nem-kívánt jel a megkívánt jeltől 100 kHz távolságban a megkívánt jelet 46 dB-el haladja meg;

d) a nem-kívánt jel a megkívánt jeltől 150 kHz, vagy annál nagyobb távolságban a megkívánt jelet 50 dB-el haladja meg.

2.6.2.1.2 Abból a célból, hogy a 100 kHz-es csatorna elosztásra tervezett vevőknek védelmet biztosítsanak, megválasztásra kerültek azok a minimális elkülönítések, amelyek a következő minimális jel arányokat a szolgáltatási térben biztosítják:

a) a megkívánt jel az egy nem-kívánt közös csatorna jelet 20 dB-el, vagy többel haladja meg;

b) a nem-kívánt jel a megkívánt jeltől 50 kHz távolságban a megkívánt jelet 7 dB-el haladja meg;

c) a nem-kívánt jel a megkívánt jeltől 100 kHz távolságban a megkívánt jelet 46 dB-el haladja meg;

d) a nem-kívánt jel a megkívánt jeltől 150 kHz, vagy annál nagyobb távolságban a megkívánt jelet 50 dB-el haladja meg.

2.6.2.2 *ILS siklópálya vevők*

2.6.2.2.1 Abból a célból, hogy a 150 kHz-es csatorna elosztásra tervezett vevőknek védelmet biztosítsanak, megválasztásra kerültek azok a minimális elkülönítések, amelyek a következő minimális jel arányokat a szolgáltatási térben biztosítják:

a) a megkívánt jel az egy nem-kívánt közös csatorna jelet 20 dB-el, vagy többel haladja meg;

b) a nem-kívánt siklópálya jel a megkívánt jeltől 150 kHz távolságban a megkívánt jelet 20 dB-el haladja meg;

c) a nem-kívánt siklópálya jel a megkívánt jeltől 300 kHz távolságban a megkívánt jelet 40 dB-el haladja meg.

2.6.2.2.2 Abból a célból, hogy a 300 kHz-es csatorna elosztásra tervezett vevőknek védelmet biztosítsanak, megválasztásra kerültek azok a minimális elkülönítések, amelyek a következő minimális jel arányokat a szolgáltatási térben biztosítják:

a) a megkívánt jel az egy nem-kívánt közös csatorna jelet 20 dB-el, vagy többel haladja meg;

b) a nem-kívánt siklópálya jel a megkívánt jeltől 150 kHz távolságban ne haladja meg a megkívánt jelet (0 dB jel arány);

c) a nem-kívánt siklópálya jel a megkívánt jeltől 300 kHz távolságban a megkívánt jelet 20 dB-el haladja meg;

d) a nem-kívánt siklópálya jel a megkívánt jeltől 450 kHz, vagy nagyobb távolságban a megkívánt jelet 40 dB-el haladja meg.

2.6.3 A számítások azon az alapfeltételen alapulnak, hogy a megkívánt jelnek biztosított védelem a nem-kívánt jel zavaró hatásával szemben 20 dB legyen. Ez az ILS szolgáltatási hatótávolsága határánál 15 mikroampernél nem nagyobb zavarásnak felel meg.

2.6.4 Amennyiben a megkívánt és a nem-kívánt vivőfrekvenciák egy interferencia hangot hoznak létre, ez a védelmi arány biztosítja azt, hogy az a műszereket nem befolyásolja. Azonban azoknál az eseteknél, ahol egy beszédüzemű berendezés használatos, ott az interferencia hang azt a berendezést zavarhatja.

2.6.5 Általában az ILS rendszereknek a nemzetközi használatát a 3. Fejezet 3.1.6.1.1 pontjában felsorolt frekvencia-párosítás korlátozza, ennek követelménye az, - feltéve, hogy azok az iránysáv egységre is megfelelnek - hogy a siklópálya elemeket automatikusan magukba foglalják. Bizonyos zsúfolt helyeken, ahol a frekvenciákat mind az első tizes, mind a második tizes frekvencia-pár sorozatból kell kijelölni, szükséges lehet az, hogy a sorozatból bizonyos párokat kiválogassanak, abból a célból, hogy az alábbi 2.6.6 pontban megadott minimális földrajzi elkülönítést kielégítsék.

Példa: A 3. Fejezet 3.1.6.1.1 pontjára utalva meg kell jegyezni azt, hogy az ILS 2. sorszám-párnál az iránysáv frekvenciája 109,9 MHz. A 12-es és 19-es sorszámú párok azonban, jóllehet, széles frekvencia elkülönítést biztosítanak a 2-es sorszámú ponttól, az iránysáv viszonyában a 334,1 MHz-es és a 333,5 MHz-es kijelölt frekvenciájúak a siklópályákra, és mindkettő az első szomszédos csatorna (300 kHz-es frekvencia elkülönítés) a 2-es sorszámú siklópálya csatornához viszonyítva. Ha az ILS csatornák kiválasztása vagy az első tíz, vagy a második tíz párosításra kerül korlátozásra, akkor a minimális siklópálya frekvencia elkülönítés 600 kHz lesz.

2.6.6 *A szükséges távolsági elkülönítés táblázata* [lásd a C-1. táblázatot]

2.6.7 A C-1. táblázatban megadott számok alkalmazása csak az azon alapfeltételek által meghatározott korlátozásokon belül lesz kifogástalan, amelyek magukba foglalják azt, hogy a berendezések lényegében körsugárzó jellegűek, megegyező a kisugárzott teljesítményük, és a térerő hozzávetőlegesen egyenesen arányos a magassági szög szögértékével a 10 fokig terjedő szögekre, valamint azt, hogy a légijármű antennája alapvetően irányítatlan (körkörös) jellegű.

Ha az elkülönítési távolságok jóval pontosabb meghatározására van szükség a frekvencia-zsúfolt körzetekben, ott azt a minden egyes berendezésre vonatkozó megfelelő terjedési görbékkel lehet meghatározni, figyelembe véve a meghatározott irányítottsági tényezőket, a kisugárzott teljesítmény jellemzőket és az olyan üzemeltetési követelményeket, mint a fedésterület. Ahol lecsökkentett elkülönítési távolságokat határoznak meg az irányítottságot stb. figyelembe véve, ott - amikor csak lehetséges - légi ellenőrzésekkel méréseket kell végezni az ILS védettségi pontjánál, és a megközelítési útirány minden pontján "bizonyítani" kell, hogy lehetséges-e a legkevesebb 20 dB-es védettség biztosításának a gyakorlati elérése.

2.7 Az iránysáv és siklópálya fedések létrehozása két rádiófrekvenciás vivőhullámmal

2.7.1 Az iránysáv fedés létrehozható két, az iránysáv frekvencia csatornán belül egymástól elválasztott különböző vivőhullámon kisugárzott összetett térerősség elosztás segítségével. Az egyik térerősség elosztás megadja a pontos iránysáv és eltolódási jelzéseket az első iránysáv szektorban, a másik pedig biztosítja az ILS jelzéseket az első iránysáv szektoron kívül azért, hogy a 3. Fejezet 3.1.3.3 és 3.1.3.7 pontjában leírt fedésterületi követelményeket kielégítse.
A jelek közötti megkülönböztetés a fedélzeti vevőkészülékben az erősebb jelnek a vevőberendezés általi befogásával történik. A befogás hatásossága az alkalmazott detektor típusától függ, általában azonban, ha a két jel közötti arány 10 dB, vagy annál nagyobb nagyságrendű, akkor a gyengébb jel nem idéz elő lényegesen nagy hibákat a demodulált kimenő jelben. Az első irányszektoron belüli legelőnyösebb teljesítmény elérése érdekében a következő útmutató anyagot kell alkalmazni a két vivőhullámú iránysáv adó rendszerek üzemeltetésénél.

2.7.2 Az iránysáv adót úgy kell megtervezni és karbantartani, hogy a két kisugárzott térbeli jel aránya az első irányszektoron ne csökkenjen 10 dB alá. Különös figyelmet kell fordítani a két antenna-rendszer által létrehozott függőleges szirom szerkezetére, ami magasságban különböző és távolságban elválasztott lehet, és ezáltal változásokat hozhat létre a jel erősségek arányában a megközelítés során.

2.7.3 A vevő átviteli sávszűrőjének hullámosságára megengedett 6 dB miatt az iránysáv vevőnél érzékenységi eltérés fordulhat elő akkor, amikor a biztonsági vezetési frekvenciát eltávolítják az irányvezetési frekvenciáról. Ennek a hatásnak a csökkentésére - különösen a III. Kategóriájú üzemeltetéseknél - az irányvezetési-biztonsági vezetési jel arányát 10 dB-ről 16 dB-re kell növelni.

2.7.4 A hibák kockázatát tovább csökkenti az, ha a két kisugárzott jel aránya a 10 dB alá csökken, és a két jelből eredő névleges iránysáv vonal irányítottsági különbségét olyan alacsonyan kell tartani, amennyire az csak lehetséges.

2.7.5 Azoknál a siklópályáknál, amelyeknél alkalmazzák a két vivőhullámot, az összetett térerősség eloszlás létrehozására ugyanazon a rádiófrekvenciás csatornán használják fel. Az antennák különleges kialakításai és az antenna áramok elosztása és fázisolása lehetővé teheti a siklópályaadó berendezések olyan különleges terepviszonyú helyszíneken történő telepítését is, ahol egyébként nehézséget okozna az egy-frekvenciás rendszer elhelyezése. Az ilyen helyszíneken javulás érhető el az alacsony szögű sugárzás csökkentésével. A második vivőhullámot a siklópálya alatti körzet fedésének biztosítására használják.

2.8 Integritás és a szolgáltatás folyamatossága - ILS földi berendezés

2.8.1 Bevezetés

2.8.1.1 Ennek az anyagnak az a célja, hogy tisztázza az ILS iránysáv és siklópálya földi berendezés szolgáltatási céljainak integritását és folyamatosságát, illetve útmutatóul szolgáljon a mérnöki tervezéshez és a berendezés rendszer-jellemzőihez. A szolgáltatás integritását és folyamatosságát üzemeltetési nézőpontból szükségszerűen ismerni kell annak érdekében, hogy döntés szülessen arról az üzemeltetési alkalmazásról, amelyet az ILS alá tud támasztani.

2.8.1.2 Általánosan elfogadott az, hogy az üzemeltetési céltól függetlenül, a leszállás során a végzetes baleset bekövetkezésének átlagos mértéke az egész rendszer - amelyet a földi berendezés, a légijármű és a légijárművezető képez - hibái, vagy hiányosságai miatt nem haladhatják meg az 1×10^{-7} valószínűséget. Erre a követelményre gyakran általános kockázati tényezőként utalnak.

2.8.1.3 Egy I. Kategóriájú üzemeltetés esetén, annak a felelőssége, hogy a fenti célok biztosításra kerülnek, a légijármű vezetőjére van ráruházva. A III. Kategóriájú üzemeltetéseknél a fenti cél a szükséges, de most ahhoz hozzátartozik az egész rendszer. Ebben az összefüggésben az a legfontosabb, hogy törekedjenek a földi berendezés szolgáltatása legmagasabb szintű integritásának és folyamatosságának elérésére. Az integritás annak biztosításához szükséges, hogy a megközelítésben lévő légijármű részére alacsony legyen a hamis útirány-vezetés vételének valószínűsége; a szolgáltatás folyamatossága annak biztosításához szükséges, hogy a légijármű részére a megközelítés végső szakaszaiban kicsi legyen annak valószínűsége, hogy az útirány-vezetési jel 'elveszik'.

2.8.1.4 Úgy látszik, hogy a különféle üzemeltetési követelményeknek a szolgáltatás különféle integritási és folyamatossági céljai felelnek meg. Az alábbi 2.14 pont a szolgáltatás integritásának és folyamatosságának négy szintjét állapítja meg, és írja le.

2.8.2 A szolgáltatási szintek integritásának és folyamatosságának megvalósítására és megőrzésére vonatkozó útmutató anyag

2.8.2.1 Egy integritás hiba akkor fordulhat elő, amikor egy olyan jel kerül kisugárzásra, amely a meghatározott tűréshatárokon "kívül van", vagy azért, mert a felügyelő egység nem ismeri fel, vagy azért, mert az ellenőrző áramkörök elmulasztják a hibás jel eltávolítását. Az ilyen hiba egy veszélyhelyzet részét képezheti, ha nagy hibát eredményez.

2.8.2.2 Nyilvánvalóan nem az összes integritás hiba veszélyes a megközelítés valamennyi szakaszában. Például a megközelítés kritikus szakaszai során az iránysáv szélességben nagy hibát, vagy irányvonal eltolódást létrehozó észrevétlen hibának különleges jelentősége van, ellenben egy, a modulációs mélység, az iránysáv, vagy a siklópálya biztonsági-vezetési jelekben és az iránysáv azonosítóban előforduló észre nem vett jel elvesztés nem fog szükségszerűen veszélyes helyzetet létrehozni. Azok a meghatározási ismérvek azonban, hogy melyik hiba mód lényeges, magukba foglalják az összes olyan veszedelmes hiba körülményt, ami nem kétségbevonhatatlanul nyilvánvaló az automatikus repülési rendszer, vagy a légijármű vezetője részére.

2.8.2.3 Különösen fontos az, hogy olyan felügyelő rendszerek tervezésre kerüljenek, amelyek biztosítják a hibamentes üzemeltetést a 3. Fejezet 3.1.3.11.4 és 3.1.5.7.4 pontjában leírt Szabványoknak való megfeleléssel. Ez gyakran szigorú tervezési elemzést igényel. A felügyelő rendszer hibái különben lehetővé tehetik a hibás jelek kisugárzását. Néhány olyan lehetséges körülmény, ami a veszély részét képezheti, a II. és III. Kategóriájú üzemeltetési teljesítményeknél:

a) egy nem észlelt, jelentősen az iránysáv, vagy a siklópálya felügyelő rendszere ellenőrzési határain kívülre történő irányvonal eltolódás;

b) egy nem észlelt olyan hiba, ami jelentősen megváltoztatja az iránysáv szélességet és a siklópálya érzékenységet;

c) egy nem észlelt olyan hiba, ami az iránysáv lassú ciklikus elmozdulását idézi elő, olyan, a megközelítést végrehajtó légijármű által szemmel látható hibákat létrehozóan, ami amplitúdóban jelentős mértékben meghaladja a 3. Fejezet 3.1.3.4.2 pontjában az iránysávadóra és a 3. Fejezet 3.1.5.4.2 pontjában a siklópályaadóra az ILS "B"- és "T"-pontja közötti értékre előírtakat.

2.8.2.4 A védelem legmagasabb szintje a felügyelő egység és a hozzá kapcsolódó vezérlő rendszer észre nem vett hibájának kockázata ellen szükséges. Ezt úgy lehet elérni, hogy gondosan megtervezik az ilyen előfordulások lehetőségének az alacsony szintre való csökkentését, és elvégzik a felügyelő rendszer teljesítményének karbantartási ellenőrzését olyan időközönként, amelyet a tervezési elemzés határozott meg. Egy ilyen elemzést fel lehet használni a rendszer integritás szintjének a minden egyes leszállásra vonatkozó kiszámítására. A következő képletet meghatározott típusú ILS berendezésekre lehet alkalmazni, és egy példát ad a rendszer integritás, *I*, meghatározására - az észre nem vett hibás kisugárzású adások valószínűségének, *P*, kiszámításából.

(1) $I = 1 - P$

$$P = \frac{T_1 T_2}{\alpha_1 \alpha_2 M_1 M_2} \quad \text{amikor } T_1 < T_2$$

ahol:

I = integritás;

P = az adó és a felügyelő rendszerben előforduló olyan egyidejű hibák valószínűsége, amelyek észre nem vett hibás sugárzást eredményeznek;

M_1 = adó meghibásodások közötti átlagos idő (MTBF);

M_2 = a felügyelő és a hozzá kapcsolódó vezérlő rendszer meghibásodásai közötti átlagos idő;

1
α_1 = az adóban bekövetkező olyan meghibásodások aránya, amely hibás jelek kisugárzását eredményezte az összes adó hiba gyakoriságához viszonyítva;
1
α_2 = a felügyelő és a hozzá kapcsolódó vezérlő rendszer olyan meghibásodási gyakoriságának aránya, amely egy hibás jel kimutatására való képtelenséget eredményezett az összes, a a felügyelő és a hozzá kapcsolódó vezérlő rendszer hiba gyakoriságához viszonyítva;

T_1 = az adó ellenőrzések közötti időtartam (órákban);

T_2 = a felügyelő és a hozzá kapcsolódó vezérlő rendszer ellenőrzései közötti időtartam (órákban).

Amikor a $T_1 \geq T_2$, akkor a felügyelő rendszer ellenőrzéseit adó ellenőrzésnek lehet tekinteni. Ebben az esetben ennek megfelelően a $T_1 = T_2$ és a képlet a következő lesz:

(2) $$P = \frac{T_2^2}{\alpha_1 \alpha_2 M_1 M_2}$$

2.8.2.5 Az integritást illetően, mivel a felügyelő, vagy vezérlő rendszeren belüli veszélyes meghibásodás előfordulásának valószínűsége rendkívüli módon távoli, azért az, hogy egy magasfokú bizonyossággal megállapítsák a szükséges integritás szintet, szükségessé tenne egy olyan többsávos kiértékelési időtartamot, ami a berendezés meghibásodások közötti átlagos idő /MTBF/ meghatározásához szükséges. Az ilyen elnyújtott időtartam elfogadhatatlan, és ennek megfelelően a megkívánt integritás szintet csak a berendezés szigorú tervezési elemzésével lehet előre 'megjósolni'.

2.8.2.6 A berendezés meghibásodások közötti átlag idejét /MTBF/ és a szolgáltatási folyamatosságát az alap felépítési jellemzők és az üzemeltetési környezet szabályozza. A berendezések felépítésénél a legmegfelelőbb mérnöki munkát, anyagokat és alkatrészeket kell alkalmazni, és szigorú ellenőrzéseket kell végrehajtani a gyártás során. Alapvetően biztosítani kell azt, hogy a berendezést olyan környezeti feltételek mellett üzemeltessék, amit a gyártó meghatározott. A gyártót fel kell kérni arra, hogy biztosítsa azokat a tervezési részleteket, ami lehetővé teszi a meghibásodások közötti átlagos időnek /MTBF/ és a szolgáltatás folyamatosságának a kiszámíthatóságát. Az az elvárás, hogy a berendezés meghibásodások közötti átlag idejét egy üzemeltetési körülmények melletti értékeléssel kell megerősíteni, az üzemeltetési tényezőket számításba véve, például a repülőtéri környezetet, a zord éghajlati körülményeket, az elektromos energiaellátás rendelkezésre állását és a karbantartás minőségét és gyakoriságát. A szolgáltatás 2., 3. vagy 4. szintű integritása és szolgáltatási folyamatossága kiértékelési időtartamának elegendő hosszúságúnak kell lenni ahhoz, hogy a megkívánt szint magasfokú bizonyossággal történő elérését meghatározzák. A következő mérlegelendő tényezőket kell alkalmazni:

a) a minimálisan elfogadható bizonyossági szint 60 százalék. Az ILS szolgáltatási szintjétől függően ez eltérő értékelési időtartamokat eredményezhet. A repülőtéri környezet hatásának értékelésénél jellemzően egy egy-éves időtartamú minimális kiértékelési időtartam szükséges egy meghatározott repülőtéren. Ennek az időtartamnak a lecsökkentése olyan esetekben lehetséges, ahol az üzemeltetési környezet jól ellenőrzött és egy másik, már „bizonyított” telepítéshez hasonló. Az azonos típusú és hasonló üzemeltetési és környezeti körülmények melletti üzemeltetésre később telepített berendezésnél azután eltérő berendezés értékelési időtartamok következhetnek.
Jellemzően ezekre a későbbi telepítésű berendezésekre a minimális időtartamok a 2. szolgáltatási szintre 1600 óra, a 3.szolgáltatási szintre 3200 óra és a 4.szolgáltatási szintre legkevesebb 6400 óra. Ahol több egyforma rendszert üzemeltetnek hasonló körülmények mellett, ott lehetséges az, hogy az értékelést az összes rendszer halmozott üzemeltetési óráira alapozzák. Ez egy lecsökkentett értékelési időtartamot eredményez; és

b) az értékelési időtartam alatt el kell dönteni azt, tervezési hiba okozta-e az egyes leállásokat, vagy egy olyan alkatrész hibája, amelynek ez a szabvány meghibásodási gyakorisága. A tervezési hibákhoz tartoznak például azok az üzemi alkatrészek, amelyek az előírásaikon túli tartományban működtek (túlmelegedés, túláram, túlfeszültség stb. körülmények). Ezeket a tervezési hibákat úgy lehet kezelni, hogy az üzemeltetési körülményeket visszaveszik az alkatrész szabvány üzemeltetési körülményeire, vagy úgy, hogy az alkatrészt kicserélik egy olyannal, ami az üzemeltetési körülményeknek jobban megfelel.
Ha a tervezési hibát ily módon kezelik, akkor az értékelést tovább lehet folytatni, és ezt a leállást nem kell számolni, alapfeltételként elfogadva azt, hogy ez a tervezési hiba - nagy valószínűséggel - nem fog megismétlődni. Ugyanez alkalmazható bármely olyan eset miatti leállásra, amelyet az üzemeltetési körülmények végleges változtatásával csökkenteni lehet.

2.8.2.7 A szolgáltatás működési folyamatosságát az üzemszünetek közötti átlagos idővel /MTBO/ lehet kimutatni, ahol az üzemszünetet a térbeli-jel bármilyen előre nem várt megszűnéseként lehet meghatározni. Ezt a teljes berendezésre vonatkozó működőképes állapotnak az üzemeltetési hibákkal történő elosztásával kell kiszámítani. A meghibásodások közötti átlagos idő /MTBF/ és az üzemszünetek közötti átlagos idő /MTBO/ nem mindig egyenlő, mivel nem minden berendezés hiba fog szükségszerűen egy üzemszünetet okozni, például egy olyan eset, amikor az adó hibája a készenléti adóra történő azonnali átállást hozza létre. Az alábbi 2.14 pontban megadott, a szolgáltatás folyamatosságára várható, üzemszünetek közötti /MTBO/ minimális átlagos idő értékek több rendszer többéves üzemeltetési tapasztalataiból kerültek levezetésre. Annak meghatározásához, hogy egy ILS berendezés működési jegyzőkönyvei beigazolják-e a 2., 3. vagy 4. szint kijelölését, a következő tényezők szakszerű megfontolásai szükségesek:

1) a működési jegyzőkönyvek és az egy megfelelő időtartamon keresztül megalapozott rendszer-felhasználási tapasztalatok (lásd a 2.8.2.6 pontot);

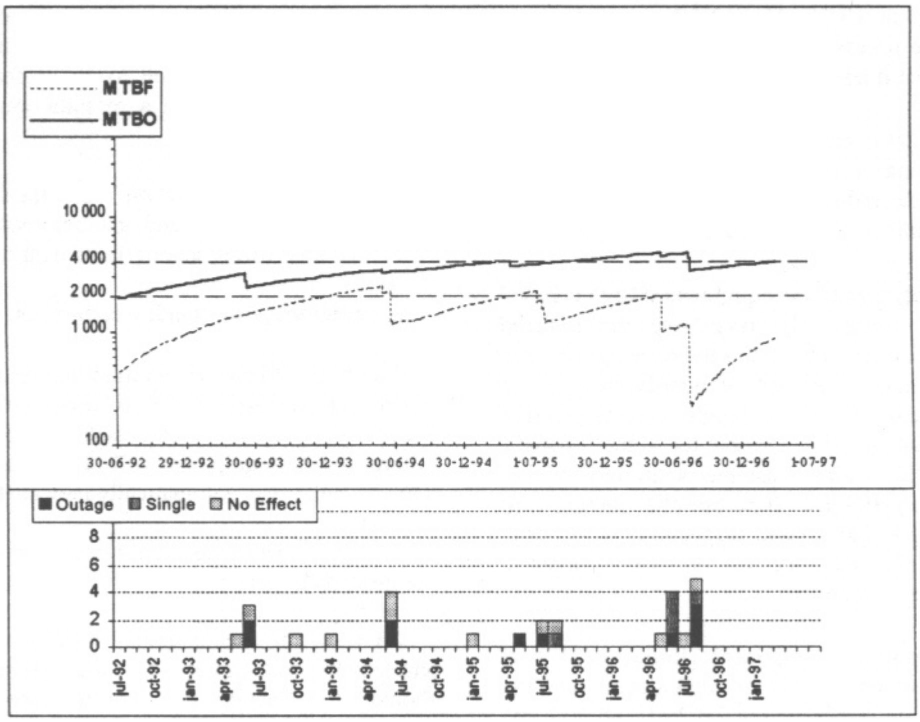
2) az ilyen típusú ILS berendezésre megállapított átlagosan elért üzemszünetek közötti átlagos idő /MBTO/; és

3) a meghibásodások gyakoriságának /irányzata/ trendje.

Egy kiosztott kijelölést nem lehet gyakran változtatgatni. Egy adott telepítésű berendezés működése kiértékelésének alkalmas módszere az, hogy rögzítik a hibákat, és kiszámítják a berendezés utolsó öt - nyolc hibájának üzemszünetek közötti átlagos idejét. Erre a módszerre egy jellemző rögzítési módot ad meg a C-12A és C-12B ábra.

2.8.2.8 A berendezés értékelése során és az üzemeltetési szolgálatba állítását követően folyamatosan jegyzőkönyvezni kell az összes berendezés hibát, vagy üzemszünetet azért, hogy megerősítsék a kívánt szolgáltatási folyamatosság fenntartását.

XX IRÁNYSÁVADÓ

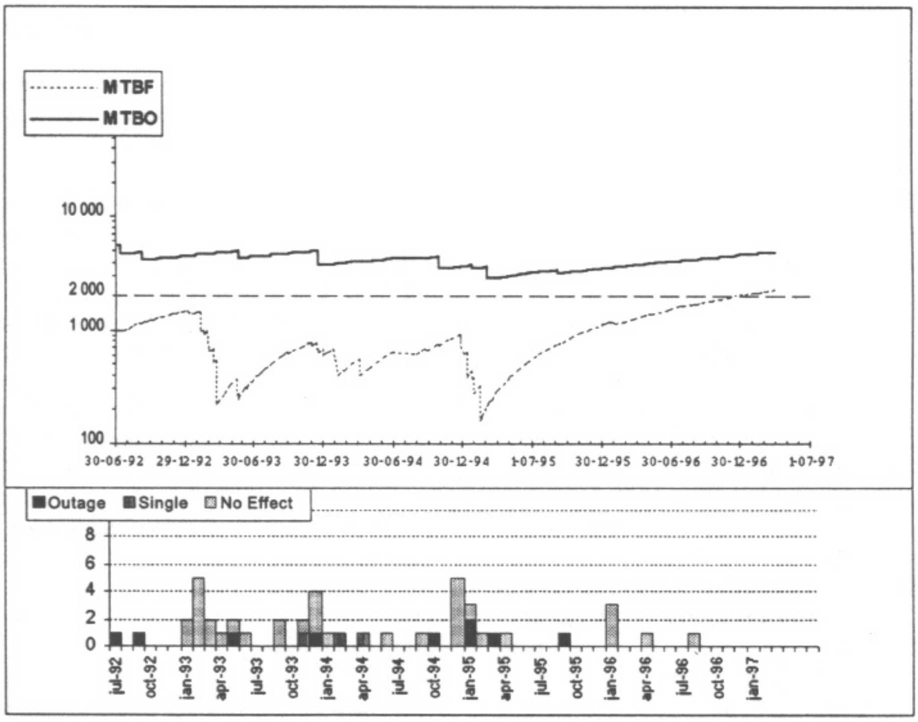


C-12A. ábra: Példa az iránysávadó üzemszünetek jegyzőkönyvi rögzítésére

Jelmagyarázat:

MTBF = Meghibásodások közötti átlagos idő
MTBO = Üzemszünetek közötti átlagos idő
Outage = Leállás
Single = Egyes
No Effect = Nincs hatás

XX SIKLÓPÁLYAADÓ



C-12B: Példa a siklópályaadó üzem szünetek jegyzőkönyvi rögzítésére

Jelmagyarázat:

MTBF = Meghibásodások közötti átlagos idő
MTBO = Üzemszünetek közötti átlagos idő
Outage = Leállás
Single = Egyes
No Effect = Nincs hatás

2.8.2.9 A következő kialakítás példát ad egy olyan tartalékolt berendezési elrendezésre, ami valószínűleg megfelel a 3. és 4. szintű integritási és szolgáltatás folyamatossági céloknak. Az iránysávadó berendezést két - folyamatosan működő - adó alkotja, az egyik az antennára kapcsolva és a készenléti pedig egy műterhelésre kötve. Ezekhez az adókhoz kapcsolódik a következő funkciókat ellátó működési felügyelő rendszer:

a) megfigyeli, hogy a fő adó és az antenna-rendszer üzeme az előírt határértékeken belül van-e a több felügyelő egység közötti többségi választás eszközével;

b) a készenléti berendezés felügyeletével.

2.8.2.9.1 Amikor a felügyelő rendszer a berendezések valamelyikét 'kiselejtezi', akkor a berendezés szolgáltatási szintjének folyamatossága le fog csökkenni azért, mert a többi berendezés hibájából bekövetkező jel megszűnés valószínűsége meg fog növekedni. Ezt a teljesítmény változást automatikusan ki kell jelezni a távvezérlő helyeken.

2.8.2.9.2 Egy, az iránysávadóhoz alkalmazott rendszerrel megegyező felügyelő rendszer kialakítást kell alkalmazni a siklópályaadó berendezésnél.

2.8.2.9.3 A fő és a készenléti adók közötti kölcsönös interferencia csökkentése érdekében, azaz az utóbbitól származó minden parazita sugárzás ellen annak a sugárzása legalább
50 dB-el a fő adó vivőhullám szintje alatt kell legyen az antenna rendszernél mérve.

2.8.2.9.4 A fenti példában a berendezésnek magába kell foglalni egy olyan felszerelést, ami lehetővé teszi a felügyelő rendszer ellenőrzéseit a gyártó által meghatározott, a gyártó tervezési elemzéséből következő időközönként, a szükséges integritási szint elérésének biztosítására. Az ilyen ellenőrzések, amelyek kézi, vagy automatikus ellenőrzések lehetnek, azt az eszközt biztosítják, amely megvizsgálja a felügyelő rendszer pontos működését, beleértve az ellenőrző áramköröket és az átváltó kapcsoló rendszert is. Az automatikus felügyelő rendszeri integritás ellenőrzések elfogadásának az az előnye, hogy az iránysáv és a siklópálya által biztosított szükséges üzemeltetési szolgáltatásban nem lesz megszakítás. Amikor ezt a technikát alkalmazzák, akkor fontos annak a biztosítása, hogy az ellenőrző ciklus teljes időtartama elég rövid legyen ahhoz, hogy ne haladja meg a 3. Fejezet 3.1.3.11.3 vagy 3.1.5.7.3 pontjában előírt teljes időtartamot.

2.8.2.9.5 A berendezés működésének az elsődleges áramellátás hibája miatti megszakadását egy megfelelő készenléti áramellátás biztosításával lehet elkerülni, például telepekkel, vagy "szünetmentes" generátorokkal. Ilyen feltételek mellett a berendezés képes lesz a folyamatos működésre azon időtartam alatt, amikor a légijármű a megközelítés kritikus szakaszaiban lehet.

2.8.2.9.6 A rendszer kritikus alkotó részeinek meghibásodására - mint például az elsődleges áramellátás hibájára - vonatkozóan figyelmeztetéseket kell adni a kijelölt ellenőrző pontokon.

2.8.2.10 Abból a célból, hogy az olyan berendezések hibáit csökkentsék, amelyek a felügyelő rendszer tűrési határértékeinek közelében üzemelnek, a felügyelő rendszer részére hasznos lehet az, hogy egy olyan rendszert iktassanak be, ami egy előzetes riasztó figyelmeztető jelet ad a kijelölt vezérlő pontokra akkor, amikor az ellenőrzött paraméterek elérik azt a határt, ami a felügyelő rendszer figyelmeztető jelzési határértékeinek a 75 százalékával egyenlő.

2.8.2.11 A térbeli-jel integritásának az olyan csökkenéssel szembeni védelmét is figyelembe kell venni, amit az ILS frekvenciasávra ható külső rádió interferencia okozhat, vagy az ILS jelek visszasugárzásából eredhet. Az utóbbira vonatkozóan a kritikus és az érzékenységi területek védelme érdekében végrehajtandó intézkedések a fenti 2.1.10 pontban az általános előírásoknál kerültek megadásra. A rádió interferenciára vonatkozóan szükséges lehet annak rendszeres időközönként történő felülvizsgálata, hogy az interferencia szintje nem jelent-e veszélyt.

2.8.2.12 Egy távolban elhelyezett felügyelő berendezés kiegészítő védelmet nyújthat azáltal, hogy figyelmeztető jelzést biztosít az ellen az egészen ritka valószínűségű - az iránysávadó berendezéstől eredő - hamis információ sugárzás ellen, amelyre a 2.8.5 pontban leírtak utalnak.

2.8.2.13 Általában véve az ellenőrző rendszerek berendezéseinek tervezése azon az alapelven alapszik, hogy folyamatosan megfigyeljék a kisugárzott térbeli-jelet a fedésterületi tér meghatározott pontjaiban azért, hogy biztosítva legyen a 3. Fejezet 3.1.3.11 és 3.1.5.7 pontjaiban meghatározott Szabványoknak való megfelelés.
Jóllehet, az ilyen felügyelet bizonyos mértékben jelzést biztosít arról, hogy a térbeli-jel a fedésterületi térben az összes többi ponton is hasonlóképpen a tűréshatáron belül van, ez mégis nagymértékben csak következtetés. Ennek megfelelően elengedhetetlen az, hogy szigorú légi és földi ellenőrzéseket hajtsanak végre rendszeres időközönként azért, hogy biztosítsák a térbeli-jel integritását a teljes fedésterületi téren belül.

2.8.2.14 Egy, a 2.8.2.9 pontban leírtakkal megegyező berendezés rendszer és a 2.8.2.11, 2.8.2.12 és 2.8.2.13 pontokban leírt útmutatások alkalmazását lehet szabályszerűen elvárni a 2. szintű integritás és szolgáltatás folyamatossági célok eléréséhez.

2.8.2.15 A különböző típusú üzemeltetésekkel együttjáró tényezők elemzése lehetővé teszi az integritás megkívánt szintjének meghatározását, a minden egyes leszállásra vonatkozó valószínűségben kifejezve a megengedett teljes kockázati tényező követelményből meghatározva. Lásd a 2.14.2 c) pontot.

2.8.3 A III. Kategóriájú üzemeltetésekhez elengedhetetlenül szükséges szigorú integritási és szolgáltatás folyamatossági követelmények szükségessé teszik az ILS III. Teljesítmény Kategóriájú berendezések alkalmazását, azokét, amelyek a meghibásodásokkal szemben kielégítő biztonságot nyújtanak. Hibaként az van meghatározva, hogy a teljesítmény kívül van a felügyelő rendszerre a 3. Fejezet 3.1.3.11 pontjában a III. Kategóriájú iránysávadókra és a 3.1.5.7 pontjában a III. Kategóriájú siklópályaadókra meghatározott tűréshatárokon. A földi berendezés üzembiztonságának nagyon nagynak kell lenni annak biztosításához, hogy a megközelítés és a leszállás kritikus szakasza során a biztonságot ne befolyásolja hátrányosan a földi berendezés hibája akkor, amikor a légijármű olyan magasságban vagy helyzetben van, ahol már nem képes a biztonságot javító tevékenység végrehajtására. A teljesítményt az előírt határértékek között nagy valószínűséggel biztosítani kell. A berendezés megbízhatóságát a meghibásodások közötti átlag időben /MTBF/ kifejezve egyértelműen arra a rendszer alapú hiba valószínűségre kell vonatkoztatni, ami a teljes térbeli-jel bármely jellemzőjére hatással lehet. A rendszernek biztosítani kell a felügyelő rendszerek meghibásodásával szembeni legmagasabb fokú védelmet a földi berendezés teljesítményében előforduló hiba észlelése érdekében. Az az ajánlott, hogy az Államok törekedjenek olyan nagyfokú megbízhatóság elérésére, amely a technikai és gazdaságossági határral csak megvalósítható.

2.8.3.1 A következő kialakítás példát ad egy olyan kettős tartalékolt berendezési elrendezésre, ami megfelel a III. Kategóriájú üzemeltetésekhez. Az iránysávadó berendezést két folyamatosan működő adó alkotja, az egyik egy antenna terhelésre kapcsolva. Ezekhez az adókhoz kapcsolódik - a következő funkciókat ellátó - működési felügyelő rendszer:

a) megfigyeli, hogy a fő adó és az antenna-rendszer üzeme az előírt határértékeken belül van-e a több felügyelő egység közötti többségi választás eszközével;

b) a készenléti berendezés felügyeletével.

2.8.3.1.1 Amikor a felügyelő rendszer a berendezések valamelyikét 'kiselejtezi', akkor a berendezés a továbbiakban nem fog megfelelni a III. Kategóriájú állapotnak, mert a többi berendezés hibájából bekövetkező jel megszűnés valószínűsége túl magas lesz. Ezt az alacsonyabb kategóriára való visszaállást automatikusan ki kell jelezni a távvezérlő helyekre.

2.8.3.1.2 Egy, a siklópályaadóhoz alkalmazottal megegyező felügyelő rendszer kialakítást kell alkalmazni.

2.8.3.1.3 A fő és a készenléti adók közötti kölcsönös interferencia csökkentésére, azaz az utóbbitól származó minden parazita sugárzás ellen annak a sugárzása legalább 50 dB-el a fő adó vivőhullám szintje alatt kell legyen az antenna rendszernél mérve.

2.8.3.2 A védelem legmagasabb szintje a felügyelő rendszer észre nem vett meghibásodás következménye ellen szükséges. Ezt úgy lehet elérni, hogy gondosan megtervezik az ilyen előfordulások lehetőségének alacsony szintre való csökkentését, és elvégzik a felügyelő rendszer teljesítményének karbantartási ellenőrzését olyan időközönként, amit a tervezési elemzés határozott meg.

2.8.4 A II. és III. Kategóriájú ILS iránysáv- és siklópályaadó földi berendezésekre alkalmazható kiegészítő útmutató anyagot az alábbiakban adjuk meg.

2.8.4.1 A berendezés megbízhatóságát az alap felépítési jellemzők és az üzemeltetési környezet 'szabályozza'. A berendezések felépítésénél a legmegfelelőbb tervezési munkát, anyagokat és alkatrészeket kell alkalmazni, és szigorú ellenőrzést kell alkalmazni a gyártás során. A berendezést azoknál a környezeti körülményeknél kell üzemeltetni, amelyek megfelelnek a gyártók tervezési követelményeinek. Az az elvárás, hogy a berendezés megbízhatóságát elemzéssel meg kell erősíteni a II. és III. Kategóriájú szolgáltatás bevezetése előtt. Tervezési elemzéssel kell felülvizsgálni a berendezés előre meghatározott teljesítményét.

2.8.5 Az iránysáv adó távolban telepített felügyelő berendezéseire vonatkozó útmutató anyagot az alábbiakban adjuk meg.

2.8.5.1 A távolban telepített felügyelő berendezéseket az iránysáv beállításának ellenőrzésére biztosítják, de fel lehet használni az iránysáv érzékenységének ellenőrzésére is. A távolban telepített felügyelő berendezés a beépített és a közelben telepített felügyelő berendezéstől függetlenül működik. Elsődleges célja az, hogy az iránysáv hibás beállításának veszélye ellen vagy a közelben telepített, illetve a beépített felügyelő berendezések meghibásodása ellen védelmet nyújtson. Azonkívül a távolban telepített felügyelő rendszer növelni fogja a kombinált felügyelő rendszernek azt a képességét, hogy reagáljon a sugárzó elemek fizikai változásaiból, vagy a földi reflexiós jellemzők eltéréséből eredő hatásokra. Ezenkívül még azokat a többutas terjedési hatásokat és futópálya körzeti zavaró tényezőket, - amelyeket a közelben telepített és a beépített felügyelő rendszerek nem látnak, - alapjában véve ellenőrizni lehet egy, a megközelítési útvonal alá elhelyezett megfelelő vevő(k) köré épített távolban telepített felügyelő rendszer alkalmazásával. A berendezést fel lehet használni passzív, vagy 'beavatkozó' felügyelő rendszerként.

2.8.5.2 A távolban telepített felügyelő berendezést általában nélkülözhetetlennek tartják a III. Kategóriájú üzemeltetésekhez, míg a II. Kategóriához általában kívánatosnak tartják. Ezenfelül az I. Kategóriájú telepítéseknél a távolban telepített felügyelő berendezés egy értékes eszközként szolgál a hagyományos felügyelő rendszer kiegészítéseként.

2.8.5.3 Távolban telepített felügyelő berendezés által vett jelre a futópályán, vagy annak a körzetében történő légijármű mozgások rövid idejű zavaró hatást fognak gyakorolni, és a tapasztalatok azt mutatják, hogy a távolban telepített felügyelő berendezést nem célszerű beavatkozó felügyelő rendszerként alkalmazni. Amikor passzív felügyelő rendszerként használják, akkor intézkedni kell arról, hogy a minimálisra csökkentsék az ilyen átmeneti zavaró hatásokat, és lecsökkentsék a zavaró leminősítő jelzések előfordulását; az ennek elérésére szolgáló módszereket az alábbi 2.8.5.4 pont ismerteti. A távolban telepített felügyelő berendezésnek az interferencia hatásokra adott válasza lehetőséget ad arra, hogy kijelezzék a légiforgalmi irányító munkahelyeken azt, amikor az iránysáv jelek átmeneti zavaró hatása fennáll. Azonban a tapasztalatok azt mutatták, hogy azok a légijárművek mozgásai miatti zavarások, amelyek a futópályán történő mozgásokból eredhetnek - a földetérési zónát is beleértve -, nem mindig észlelhetők a távolban telepített felügyelő berendezésekkel. Ezért nem szabad elfogadni azt, hogy a távolban telepített felügyelő berendezések a futópályán történő légijármű mozgások átfogó felderítését biztosítani tudják.

2.8.5.3.1 A távolban telepített felügyelő rendszer további lehetséges alkalmazásai:

a) hasznos karbantartási eszközként szolgál egy hordozható távolban telepített ellenőrző berendezés helyett az iránysáv és/vagy az iránysáv eltérési érzékenység ellenőrzése céljára;

b) felhasználható a távolról érkező jel teljesítmény folyamatos rögzítésének biztosítására a távolról érkező jel minőségének és a jel zavarás mértékének kimutatására.

2.8.5.4 A zavaró leminősítő jelzések előfordulása lecsökentésének lehetséges módszerei a következők:

a) egy, a rendszeren belül 30-tól 120 másodperc között beállítható időkésleltetés beépítése;

b) egy olyan 'helyesség-bizonyító' technika alkalmazása, amely biztosítja azt, hogy csak azok a jelzések kerüljenek a vezérlő rendszerhez továbbításra, amelyeket átmeneti zavarok nem érintettek;

c) az aluláteresztő szűrés alkalmazása.

2.8.5.5 Egy jellemző távolban telepített felügyelő rendszer egy antennából, az ultrarövidhullámú (VHF) vevőből és a hozzá kapcsolódó azon ellenőrző egységekből áll, amelyek a modulációs mélység különbség (DDM) kijelzést, a moduláció összeg és a rádiófrekvenciás jelszint jelzését biztosítják. A vevő antenna általában irányított típusú azért, hogy a nem-kívánt interferenciát a minimálisra csökkentse, és az akadálymentességi határértéknek megfelelően a lehető legnagyobb magasságúnak kell lennie. Az iránysáv vonal felügyelésére az antenna általában a futópálya meghosszabbított középvonalában kerül elhelyezésre. Ahol kívánatos az, hogy az eltolódási érzékenységet is ellenőrizze, ott egy kiegészítő vevő és felügyelő egység kerül elhelyezésre, az antennáját a futópálya meghosszabbított középvonalának egyik oldalán megfelelően elhelyezve. Néhány rendszernél több, térben összetartóan elhelyezett antennát alkalmaznak.

2.9 Az iránysáv és siklópálya eltolódási érzékenység

2.9.1 Jóllehet, bizonyos iránysáv és siklópálya beállítások és az eltolódási érzékenység az ILS vonatkozási pontjához kapcsolódóan előírásra került, azonban ez nem azt jelenti, hogy ezeknek a paramétereknek a mérését ebben a pontban kell elvégezni.

2.9.2 Az iránysávadó felügyelő rendszerének a 3. Fejezet 3.1.3.7 és 3.1.3.11 pontjában megadott értékei és beállítási, valamint karbantartási értékhatárai az eltolódási érzékenység százalékos változásaként kerültek meghatározásra. Ez az elmélet, amely a korábbi kiadványokban lévő szögszélességi előírásokat helyettesíti, azért került bevezetésre, mert a légijármű útirány-vezetési rendszereinek reagálása közvetlenül az eltolódási érzékenységhez kapcsolódik. Meg kell jegyezni azt, hogy a szögszélesség az eltolódási érzékenységgel fordítottan arányos.

2.10 Az ILS helyjeladók telepítése

2.10.1 A belső és a középső helyjeladók közötti interferencia szempontok, valamint az üzemeltetésileg elfogadható minimális időköz a belső és a középső helyjeladó fényjelzései között, korlátozni fogják azt a maximális magasságot, amit a belső helyjeladóval jelezni lehet az ILS siklópályán a futópálya küszöbe feletti 37 m-es (120 láb) magasságra azoknál a helyjeladóknál, amelyek az Annex 10 jelenlegi tűréshatárán belül telepítenek. Egy egyedi helyszín tanulmány fogja meghatározni azt a maximális magasságot, amelyet jelezni lehet, tudomásul véve azt a tényt, hogy egy jellemző fedélzeti helyjeladó vevő berendezéssel egy 140 csomós légijármű sebességnél a középső és a belső helyjeladó közötti fényjelzésre az üzemeltetésileg minimálisan elfogadható időköz 3 másodperc nagyságrendű.

2.10.2 Olyan telepítésű ILS berendezések esetében, amikor egymáshoz közel - például 500 méteres (1 650 láb) térközzel - elhelyezett párhuzamos futópályákat szolgálnak ki, különleges intézkedések szükségesek a helyjeladók kielégítő működésének biztosításához. Egyes Államok gyakorlatilag megfelelőnek találták azt, hogy egyetlen közös felhasználású külső helyjeladót használnak mindkét ILS berendezéshez. Azonban különleges intézkedések szükségesek - például módosított sugárzási iránykarakterisztika - a középső helyjeladók esetében azért, hogy a kölcsönös interferenciát elkerüljék, különösen azoknál az eseteknél, ahol a futópályák egymástól hosszirányban lépcsőzetesen eltoltak.

2.11 A DME berendezésnek az ILS helyjeladók helyetti alkalmazása

2.11.1 Amikor egy DME berendezést használnak az ILS helyjeladók helyett, akkor a DME-t a repülőtéren úgy kell elhelyezni, hogy a nulla távolsági kijelzés egy, a futópálya közelében lévő pontnál legyen. Amikor a DME együttműködik egy nulla távolságú eltolásos ILS-el, akkor ezt a képességet ki kell zárni az RNAV megoldások közül.

2.11.2 A háromszögelési hiba csökkentése céljából a DME-t úgy kell telepíteni, hogy kis értékű szöget (például, 20 foknál kisebbet) biztosítson a megközelítési útirány és a DME-hez tartó irány között annál a pontnál, ahol a távolság információ szükséges.

2.11.3 A DME berendezésnek a középső helyjeladó helyett történő alkalmazásánál alapfeltétel az, hogy a DME rendszer pontossága 0,37 km (0,2 tengeri mérföld), vagy annál jobb legyen, és a fedélzeti kijelzés felbontóképességének olyannak kell lenni, hogy lehetséges legyen ennek a pontosságnak az elérése.

2.11.4 Jóllehet, nem kimondottan szükségszerű az, hogy a DME frekvencia párosítva legyen az iránysávadóval akkor, amikor a külső helyjeladó helyett használják, de a frekvencia párosítás mindenkor előnyös, amikor a DME az ILS-el együtt kerül felhasználásra, mivel egyszerűsíti a légijárművezető munkáját, és lehetővé teszi azt, hogy a két ILS vevővel felszerelt légijármű mindkét vevőjét az ILS csatornán használja.

2.11.5 Amikor a DME frekvenciában párosítva van az iránysávadóval, akkor a DME válaszadó azonosító jelet a frekvenciában párosított iránysávadóból "társult" jelként kell adni.

2.12 Az ILS-hez társuló tájékozódási vezetést adó kiegészítő források alkalmazása

2.12.1 Egy ILS megközelítést megkezdő légijárművet egyéb földi telepítésű berendezések, mint például VOR-ok, légtérellenőrző radar, vagy - ahol ezeket a berendezéseket nem tudták biztosítani - helyzet-meghatározó jeladók által biztosított tájékozódási vezetéssel lehet segíteni.

2.12.2 Ahol azt a meglévő közelkörzeti, vagy útvonal berendezések nem biztosítják, egy megfelelően telepített VOR berendezés hatékony átmenetet tud biztosítani az ILS-re. Ennek a célnak az eléréséhez a VOR berendezést az iránysáv irányvonalon, vagy egy olyan helyzetben lehet telepíteni, ahol az iránysáv irányvonalától olyan távolságban van, hogy egy radiálja olyan szöggel keresztezi az iránysáv irányvonalát, ami lehetővé teszi a sima átmenetet az útvonalra rácsatlakozás esetén is. A VOR telepítési helyszíne és a kívánt pont közötti távolságot ismerni kell akkor, amikor a ráállás pontosságát és a követési hibákhoz biztosított rendelkezésre álló légteret meghatározzák.

2.12.3 Ahol egy megfelelően telepített VOR biztosítása gyakorlatilag nem lehetséges, ott egy bevezető helyzet-meghatározó jeladó, vagy egy NDB tud segítséget nyújtani az ILS-re történő ráálláshoz. A berendezést az iránysávadó irányvonalában kell elhelyezni a futópálya küszöbétől megfelelő távolságra ahhoz, hogy a legmegfelelőbb ráállást biztosítsa.

2.13 ILS - I. teljesítmény kategóriájú berendezések felhasználása az automatikus megközelítések és leszállások során olyan látási körülmények esetén, ami lehetővé teszi az üzemeltetésnek a légijárművezető általi látásos ellenőrzését

2.13.1 Az ILS - I. Teljesítmény Kategóriájú berendezések megfelelő minőségűek ahhoz, hogy - olyan típusú légijármű fedélzeti repülőgép vezérlő rendszerrel társítva, amelyek nem kizárólag az ILS érzékelőktől származó útirány-vezetési tájékoztatásokra támaszkodnak - felhasználhatók legyenek azokhoz az automatikus megközelítésekhez és leszállásokhoz, amelyeket olyan látási körülmények mellett hajtanak végre, ami lehetővé teszi a légijármű vezetője részére az üzemeltetés látás szerinti ellenőrzését.

2.13.2 Ahhoz, hogy a légijármű üzemeltető vállalatokat az egyedi ILS berendezéseknek az ilyen üzemeltetésekre való megfelelőségéről történő előzetes értékelésében segítsék, kérik az Államokat, hogy tegyék közzé:

a) a 3. Fejezet 3.1 pontjától való bármilyen vonatkozású eltérést;

b) a 3. Fejezet 3.1.3.4 és 3.1.5.4 pontjában foglalt előírások teljesítésének mértékét az iránysáv és a siklópálya sugárnyaláb szerkezetére vonatkozóan; és
c) az ILS vonatkozási pontjának a futópálya küszöbe feletti magasságát.

2.13.3 Az olyan zavarok elkerülése érdekében, amelyek megakadályozhatják egy automatikus megközelítés és leszállás végrehajtását, szükséges az, hogy helyi rendelkezésekkel biztosítsák - a gyakorlatilag lehetséges mértékben - az ILS kritikus és érzékenységi területének védelmét.

2.13.4 Ahol két önálló ILS berendezés szolgálja ki egy futópálya két ellentétes végét, ott egy kényszer-kapcsolóval kell biztosítani azt, hogy csak az egyik megközelítési irányt kiszolgáló iránysávadó sugározhasson.

2.14 ILS osztályba sorolás - kiegészítő ILS leírási módszer a berendezés üzemeltetési felhasználásának elősegítése céljából

2.14.1 Az alábbiakban megadott osztályba sorolási rendszer az érvényben lévő berendezés teljesítmény kategóriákkal együtt arra a célra szolgál, hogy az ILS leírásának egy jóval átfogóbb jellegű módszerét biztosítsa.

2.14.2 Az ILS osztályba sorolás három jelcsoport felhasználásával a következők szerint kerül meghatározásra:

a) I., II. vagy III.: ezek a jelek a 3. Fejezet 3.1.3 és 3.1.5 pontjában meghatározott berendezés teljesítmény kategóriának való megfelelést jelzik;

b) A, B, C, T, D, vagy E: ezek a jelek azokat az ILS pontokat határozzák meg, ameddig az iránysáv szerkezete megfelel a 3. Fejezet 3.1.3.4.2 pontjában megadott iránysáv szerkezetnek, a T betű kivételével, ami a futópálya küszöbét jelöli. A pontok a 3. Fejezet 3.1.1 pontjában kerültek meghatározásra.

c) 1., 2., 3. vagy 4.: ezek a számok a C-2. táblázatban megadott integritási és szolgáltatás folyamatossági szintet jelzik.

Megjegyzés. - A meghatározott ILS üzemeltetéshez kapcsolódóan az a cél, hogy az integritási és szolgáltatás folyamatossági szint jellemzően a következőkhöz kapcsolódjon:

1) A 2. szintű teljesítmény célja az, hogy az ILS berendezést az olyan alacsony látástávolságú üzemeltetések alátámasztására használják, ahol az ILS irányvezetést a leszállási szakasz helyzet tájékoztatásánál látásos segédeszközökkel egészítik ki. Ez a szint kívánatos célja az I. Kategóriájú üzemeltetéseket alátámasztó berendezéseknek;

2) A 3. szintű teljesítmény célja az, hogy az ILS berendezést olyan üzemeltetések alátámasztására használják fel, amelyek magasszintű bizalmat helyeznek az ILS által nyújtott irányvezetésre egészen a földetérési pontig. Ez a szint a II. és III.A. Kategóriájú üzemeltetéseket alátámasztó berendezések szükségletének jellemzője; és

3) A 4. szintű teljesítmény célja az, hogy az ILS berendezést az olyan üzemeltetések alátámasztására használják fel, amelyek magasszintű bizalmat helyeznek az ILS által nyújtott irányvezetésre egészen a földetérési pontig és a leszállás utáni kifutás-kigurulás során. Ez a szint alapjában a III. Kategóriájú üzemeltetések teljes sorának szükségleteire vonatkozik.

C-2. táblázat: Integritási és szolgáltatás folyamatossági célok

Szint	Iránysáv, vagy siklópálya		
	Integritás	Szolgáltatás folyamatosság	Meghibásodások közötti átlag idő (óra)
1	Nincs leírva, vagy kevesebb, mint ami a 2. szinthez szükséges.		
2	1 - 10^{-7} minden egyes leszálláshoz	1 - 4 x 10^{-6} minden 15 másodperces időtartamban	1 000
3	1 - 0,5 x 10^{-9} minden egyes leszálláshoz	1 - 2 x 10^{-6} minden 15 másodperces időtartamban	2 000
4	1 - 0,5 x 10^{-9} minden egyes leszálláshoz	1 - 2 x 10^{-6} minden 30 másodperces időtartamban (iránysáv) 15 másodperc (siklópálya)	4 000 (iránysáv) 2 000 (siklópálya)

Megjegyzés. - A jelenleg már telepített berendezésekre abban az esetben, ha a 2. szintű integritási érték nem áll rendelkezésre, vagy nem lehet azonnal kiszámítani, az szükséges, hogy legalább az integritás egy részletes elemzését végezzék el az ellenőrzött meghibásodás ellen biztosított üzemeltetés biztosításához.

2.14.3 Egy példaként, egy olyan ILS - II. Teljesítmény Kategóriájú berendezés, amely kielégíti az ILS - III. Teljesítmény Kategóriájú berendezés iránysáv irányvonal szerkezeti követelményeket egészen az ILS "D" pontjáig, és megfelel a 3. szintű integritási és szolgáltatási célok folyamatosságának, a leírás szerint II/D/3 osztályú lesz.

2.14.4 Az ILS osztályok csak a földi ILS egységekre kerülnek alkalmazásra. Az üzemeltetési kategóriák figyelembevételének magába kell foglalni az olyan további kiegészítő tényezőket is, mint az üzemeltető képességei, a kritikus és az érzékenységi terület védelme eljárási követelmények, valamint az olyan kiegészítő eszközök, mint a futópálya látástávolság-mérő, fénytechnika.

2. 15 Az ILS vivőfrekvencia és fázis-moduláció

2.15.1 Az ILS rádiófrekvenciás vivőfrekvenciáján a megkívánt 90 Hz-es és 150 Hz-es amplitúdó-moduláción (AM) kívül nem-kívánt frekvencia-moduláció (FM) és/vagy fázis-moduláció (PM) fordulhat elő. Ez a nem-kívánt moduláció a középfrekvenciás szűrő átviteli sávjának hullámossága meredekségének detektálása miatt központosítási hibát okozhat az ILS vevőknél.

2.15.2 Erre a lehetőségre a továbbított rádiófrekvenciás vivő-frekvenciának egy olyan középfrekvenciába kell esni, ahol az átviteli sávnak nagy a meredeksége. A meredekség a nem-kívánt 90 Hz-es és 150 Hz-es frekvencia változásokat ugyanolyan frekvenciájú amplitúdó-modulációra alakítja át. Hasonlóképpen, a nem-kívánt 90 Hz-es és 150 Hz-es összetevők közötti frekvencia-modulációs eltérések bármilyen különbségét modulációs mélység különbséggé alakítja át, ami azután eltolást hoz létre a vevőben. A mechanizmus a fázis-modulációra megegyezik a frekvencia-modulációval, mivel a fázis-moduláció olyan frekvencia változást okoz a frekvenciában, ami a fázisban való változásnak (radiáns) a moduláló frekvenciával való szorzatával egyenlő.

2.15.3 A nem-kívánt frekvencia-moduláció és/vagy fázis-moduláció hatását a kívánt amplitúdó-modulációhoz való vektor-összeadás összegzi. A detektált frekvencia vagy fázisban vagy ellenfázisban van az amplitúdó-modulációval, attól függően, hogy a vivő középfrekvencián az átviteli sáv meredekség pozitív, vagy negatív. A detektált fázis-moduláció az amplitúdó-modulációval kvadratúra-modulációban van, és ugyancsak pozitív, vagy negatív lehet az átviteli sáv meredekségétől függően.

2.15.4 Az olyan 90 Hz-től és a 150 Hz-től eltérő frekvenciájú nem-kívánt frekvencia-moduláció és/vagy fázis-moduláció, amelyek átjuthatnak a vevő 90 Hz-es és 150 Hz-es hangfrekvenciás szűrőjén, ugyancsak változásokat okozhatnak az ILS rádiófrekvenciás vivőfrekvenciájának megkívánt 90 Hz-es és 150 Hz-es amplútidó-modulációján, és ez a vevőben modulációs mélység különbség eltolási hibát eredményez. Ennek megfelelően elengedhetetlen az, hogy amikor a nem-kívánt frekvencia-modulációs és fázis-modulációs szinteket mérik, akkor a legalább olyan széles átviteli sávú hangfrekvenciás sávszűrőket kell használni, mint amilyen hangszűrője az ILS vevőknek van. Ezek a szűrők jellemzően egy kereskedelmi moduláció-mérő ellenőrző berendezésbe - a demodulációs és a mérő áramkörök közé - kerülnek behelyezésre, annak biztosítására, hogy csak az ILS alkalmazásnál érintett spektrumsáv összetevők kerüljenek mérésre. Az ilyen mérések szabványosítására az alábbiakban megadott szűrő jellemzőket ajánljuk:

Frekvencia (Hz)	*90 Hz-es átviteli sávát-eresztő szűrő csillapítás, dB*	*150 Hz-es átviteli sáváteresztő szűrő csillapítás, dB*
≤45	-10	-16
85	-0,5	(nincs meghatározva)
90	0	-14
95	-0,5	(nincs meghatározva)
142	(nincs meghatározva)	-0,5
150	-14	0
158	(nincs meghatározva)	-0,5
≥300	-16	-10

2.15.5 Az előnyben részesített maximális határértékek - ahogy az az alábbiakban bemutatásra kerül - az EUROCAE ED-46B és ED-47B dokumentumaiban az ILS vevő központosítási hiba határokból meghatározott, a nem-kívánt modulációs szintek és a központosítási hibák között észlelt kölcsönösség eddigi legrosszabb esetein alapulnak:

A berendezés típusa	*90 Hz csúcs eltérés, FM Hz/PM radiáns (1. Megjegyzés)*	*150 Hz csúcs eltérés, FM Hz/PM radiáns (2. Megjegyzés)*	*Eltérési különbség, Hz (3. Megjegyzés)*
Iránysáv, I.Kategória	135/1,5	135/0,9	45
Iránysáv, II.Kategória	60/0,66	60/0,4	20
Iránysáv, III.Kategória	45/0,5	45/0,3	15
Siklópálya, I.Kategória	150/1,66	150/1,0	50
Siklópálya, II., vagy III. Kategória	90/1,0	90/0,6	30

1. Megjegyzés. - Ezt az oszlopot alkalmazzák a csúcs frekvenciára, vagy a fázis eltérésre, ahogy azt a 90 Hz-es hangszűrőn a 2.15.4 pontban meghatározottaknak megfelelően mérik.

2. Megjegyzés. - Ezt az oszlopot alkalmazzák a csúcs frekvenciára, vagy a fázis eltérésre, ahogy azt a 150 Hz-es hangszűrőn a 2.15.4 pontban meghatározottaknak megfelelően mérik.

3. Megjegyzés. - Ezt az oszlopot alkalmazzák a 2.15.4 pontban meghatározott szűrőkkel kapott nem-kívánt 90 Hz-es frekvencia-modulációs (vagy a megfelelő fázis-modulációs) és a 150 Hz-es frekvencia-modulációs (vagy a megfelelő fázis-modulációs) mérések közötti csúcs frekvencia eltérés különbségére. A 90 Hz-en és a 150 Hz-en mért fázis-modulációnak megfelelő eltérést az egyes radiánsban mért csúcs fázis-modulációnak az annak megfelelő Hz-ben mért moduláló frekvenciával történő megszorzásával számítják ki.

3. A VOR-ra vonatkozó anyag

3.1 A VOR kisugárzott teljesítményére (ERP) és fedésterületére vonatkozó útmutató anyag

3.1.1 A 3. Fejezet 3.3.4.2 pontjában meghatározott térerősség a következők figyelembevételén alapszik:

Légijármű fedélzeti vevő érzékenység	-117 dBW
Adás oldali veszteség, ütközési csillapítás, antenna sugárzási diagram eltérés egy izotróp antennához viszonyítva	+7 dBw
Teljesítmény szükséglet az antennánál	-110 dBW

A 100 dBW-os teljesítmény szükségletet a 118 MHz-en mínusz 107 dBW/m^2-es teljesítmény-sűrűségnél lehet elérni; a mínusz 107 dBW/m^2 90 mikrovolt/méterrel egyenlő, azaz plusz 39 dB 1 mikrovolt/méterre vonatkoztatva.

Megjegyzés. - Egy izotróp (minden irányban azonos tulajdonságú) antenna esetében a teljesítmény-sűrűséget a következő módon lehet kiszámítani:

$$P_d = P_a - 10 \log \frac{\lambda^2}{4\pi}$$

ahol:

P_d = a teljesítmény-sűrűség dBW/m^2-ben,

P_a = a teljesítmény a vételi pontnál dBW-ban,

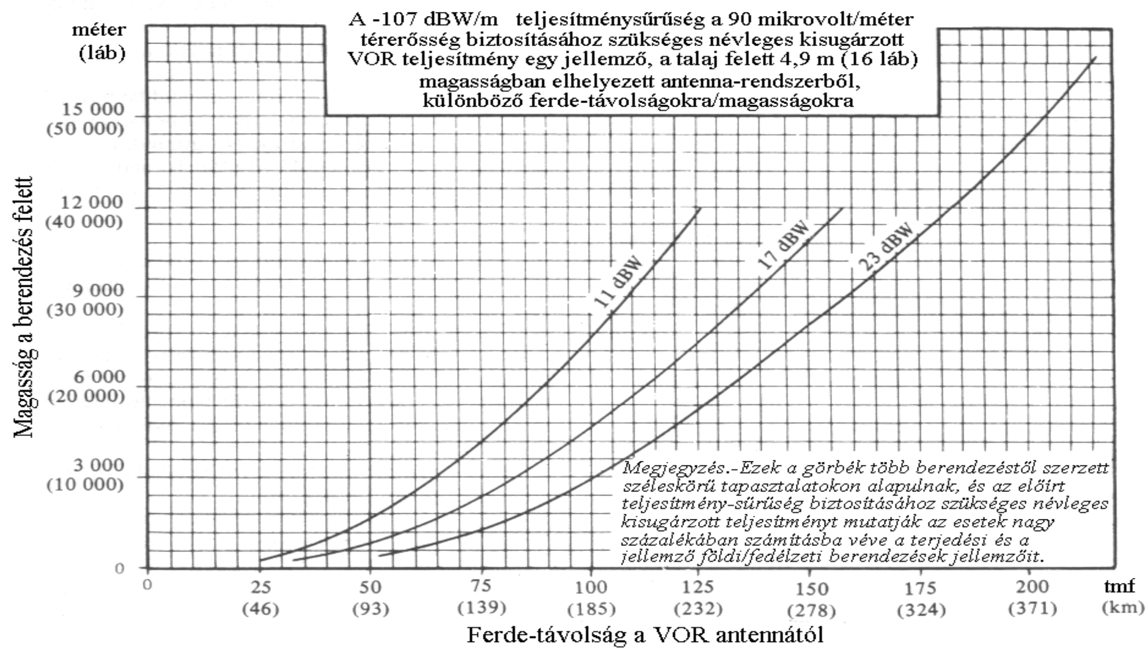
λ = a hullámhossz méterben.

3.1.2 A kisugárzott teljesítménynek /ERP/ az a szükséges névleges értéke, ami a 90 mikrovolt / méter (mínusz 107 dBW/m^2) térerősség eléréséhez kell, a C-13. számú ábrán került megadásra. A fedésterületre - bonyolult terepviszonyok és telepítési körülmények esetén - szükséges lehet az, hogy a kisugárzott teljesítményt megfelelően növeljék. Fordított esetben, a gyakorlati tapasztalat azt mutatja, hogy kedvező telepítési körülmények és kevésbé pesszimisztikus feltételek mellett gyakran azt találják, hogy a tényleges "szolgálatban" kielégítő rendszer működés érhető el alacsonyabb kisugárzott teljesítménnyel /ERP/ is.

Megjegyzés. - A névleges kisugárzott teljesítmény adatok - a magasság és távolság függvényében kifejezve - különböző forrásokból (mint például az ITU-R és NBS) származó alap elméleti adatok figyelembevételén alapulnak, és a jellemző üzemeltetési gyakorlatot tükröző tapasztalatok alapján módosítottak.

3.1.3 A C-13. számú ábra alkalmazását a következő példák mutatják be. Ahhoz, hogy a szükséges térerősséget a 342 km-es távolságban (185 tengeri mérföld) / 12 000 m magasságban (40 000 láb), a 300 km-es távolságban (162 tenger mérföld) / 12 000 m magasságban (40 000 láb), valamint a 166,5 km-es távolságban (90 tengeri mérföld) / 6 000 m-es magasságban (20 000 láb) elérjék, külön-külön plusz 23 dBW, plusz 17 dBW és plusz 11 dBW névleges kisugárzott teljesítményre van szükség.

3.1.4 Abból a célból, hogy megkönnyítsék a frekvencia és berendezés tervezést, amikor gyakorlatilag megvalósítható, a plusz 23 dBW-nak, a plusz 17 dBW-nak és a plusz 11 dBW-nak megfelelő kisugárzott teljesítmény kategóriákat kell alkalmazni. Ezeket a kisugárzott teljesítmény értékeket kell a Körzeti Tervezési Eljárások során közölni.



Megjegyzés. - Ezek a görbék csak a fedésterület teljesítmény viszonyt mutatják. A frekvencia tervezésre vonatkozó útmutatásokat a "C"- Melléklet 3.4 pontja adja meg.

C-13. ábra

3.1.5 Egy plusz 23 dBW kisugárzott teljesítménnyel működő VOR megközelíti az Annex 10-ben a korábbiakban A-kategóriájúként nevezett VOR-t (200 W-os adóteljesítmény). A kisugárzott teljesítmény és az adó kimenő teljesítménye közötti lehetséges összefüggést a következő példák mutatják be:

	I. Példa	*II. Példa*
Adó teljesítmény	+23 dBW	+18 dBW
Földi adás oldali veszteség	-2 dB	-1 dB
Az egy izotróp antennához viszonyított antenna nyereség	+2 dB	+6 dB
ERP	+23 dBW	+23 dBW

Hasonlóképpen, egy plusz 17 dBW kisugárzott teljesítménnyel működő VOR megközelíti az Annex 10-ben a korábbiakban B-kategóriájúként nevezett VOR-t (50 W-os adóteljesítmény). A kisugárzott teljesítmény és az adó kimenő teljesítménye közötti lehetséges összefüggést a következő példák mutatják be:

	I. Példa	*II. Példa*
Adó teljesítmény	+17 dBW	+10 dBW
Földi adás oldali veszteség	-2 dB	-1 dB
Az egy izotróp antennához viszonyított antenna nyereség	+2 dB	+8 dB
ERP	+17 dBW	+17 dBW

3.1.6 Elismert az, hogy a fenti kisugárzott teljesítmény /ERP/ kategóriákkal nagyobb fedésterületet lehet elérni annál, mint ami bizonyos üzemeltetési követelményekhez szükséges. Egy megfelelő kisebb fedésterületet el lehet érni egy olyan VOR berendezéssel, amelynek a kisugárzott teljesítménye körülbelül 11 dBW, a következők szerint:

	I. Példa	*II. Példa*
Adó teljesítmény	+11 dBW	+7 dBW
Földi adás oldali veszteség	-2 dB	-1 dB
Az egy izotróp antennához viszonyított antenna nyereség	+2 dB	+5 dB
ERP	+11 dBW	+11 dBW

3.2 A VOR telepítésére vonatkozó útmutató anyag

3.2.1 A telepítési helynek a környezet legmagasabb pontjának kell lenni azért, hogy a legnagyobb rálátási vonal fedésterületet kapják, és vízszintesnek, vagy az állomástól kifelé lejtőnek kell lenni (a 4 százalékot meg nem haladó lejtéssel legalább a 300 méteres (1 000 láb), de inkább a 600 méteres (2 000 láb) távolságig. A telepítési hely körvonalának az antenna rendszerhez viszonyítottan legalább 300 méteres (1 000 láb) sugárban kör alakúnak kell lenni. A telepítési helynek - amennyire az csak lehetséges - fém vezetékektől és kerítésektől messze kell lenni. A fém vezetékek és kerítések magassága az antenna rendszertől nézve nem zárhat be 1,5 foknál nagyobb függőleges szöget, vagy nem nyúlhat 0,5 foknál magasabbra a vízszintes fölé. Ezeket a határértékeket 50 százalékkal meg lehet növelni olyan kerítések, vagy vezetékek esetében, amelyek lényegében sugárirányúak az antenna rendszerre, vagy 10 foknál nem nagyobb vízszintes szöget zárnak be. Közepes magasságú, 9 méteres (30 láb) magasságot elérő egyedüli fákat a 150 méteres (500 láb) távolságon kívül meg lehet hagyni. Facsoportok 2 foknál nagyobb értékű függőleges szöget bezáróan, vagy az állomástól mért 300 m-en (1 000 láb) belül nem lehetnek. Gondoskodni kell a 600 méteres (2 000 láb) távolságig terjedően a fák eltávolításáról, ha az szükségesnek bizonyul. Semmilyen épület nem zárhat be 1,2 fokosnál nagyobb függőleges szöget, illetve nem lehet elhelyezve az állomástól mért 150 méteren (500 láb) belül.

Elhanyagolható mennyiségű fémtartalmú és kevés fém későbbi beépítésére tervezett fából készült építmények 2,5 fokos függőleges szöget bezáróan helyezhetők el.

3.2.2 Hegyvidéki terepen a legelőnyösebb telepítési hely gyakran a hegycsúcson történő telepítés lesz. A telepítési helyszínnek a legmagasabb hozzáférhető hegycsúcsnak, vagy hegynek kell lenni úgy, hogy annak tetejét legalább egy 45 méteres (150 láb) sugarú körön belül laposra kell elegyengetni. Az ilyen helyen az antenna rendszert körülbelül fél-hullámhossznyira kell a föld felszíne fölé felszerelni az elegyengetett terület közepén, és az adó épületet az elegyengetett területen túl kell elhelyezni, a lejtőn lefelé elegendő távolságra ahhoz, hogy az antenna rendszer optikai rálátási vonala alatt legyen. Az antenna rendszer optikai rálátási vonalában a 45 méter (150 láb) és a 360 méter (1 200 láb) között semmilyen talaj kiemelkedés, fák, vagy elektromos vezetékek, épületek stb. nem lehetnek.

3.3 A VOR pontosságra gyakorolt "polarizációs hiba" hatás meghatározása

3.3.1 Mivel ezideig nem lehetséges annak meghatározása, hogy mekkora a VOR sugárzás minimális megengedhető függőleges polarizációjú összetevőjének az értéke, ezért megbízható légi ellenőrzések szükségesek - az iránymérési kijelzések pontosságára ható - a "polarizációs hibák" miatti hatások megállapítására.

3.3.2 Három módszer áll rendelkezésre a "polarizációs hibák" hatásának meghatározásához:

a) 30 fokos szárnybillegtetés;

b) egy földi ellenőrző pont felett 8 útirány lerepülése;

c) egy 30 fokos bedöntésű kör lerepülése.

Ezek közül a módszerek közül az első azoknak a polarizációs hibáknak a mérésére szolgál, amik akkor jelentkeznek, amikor a légijármű a hossztengelye körül elfordul, miközben egy adott VOR radiálon repül. A második módszernél nyolc különböző géptengely irányon mérik a polarizációs hibát úgy, hogy közben a légijármű nincs bedöntési helyzetben. A harmadik módszernél valamennyi géptengely irányra mérik úgy, hogy a légijármű 30 fokos bedöntési helyzetben van. A légi ellenőrzések az alábbiak szerint kerülnek végrehajtásra:

3.3.3 *30 fokos szárnybillegtetés.* A légijármű egy állandó géptengely irányon repül a VOR berendezés felé, és lassú bedöntéseket végez a plusz 30 foktól a mínusz 30 fokosig. Az útirány eltérési kijelző áramát mérik, és átalakítják útirány eltolódási fokokká.

3.3.4 *Nyolc útirány repülése egy földi ellenőrzési pont felett.* A légijármű egy meghatározott földi ellenőrzési pont felett nyolc különböző, egymástól 45 fokkal eltérő géptengely irányon repül. Az útirány eltérési kijelző áramát rögzítik, és megjelölik azt, amikor a légijármű az ellenőrző pont felett van. Minden egyes géptengely irányszögön a kijelzett irányszöget összehasonlítják azzal a kijelzett iránryméréssel, ami akkor van, amikor a légijármű a VOR felé repül, és amikor az ellenőrző pont felett van.

3.3.5 *30 fokos bedöntésű körrepülés.* A légijármű először a VOR berendezés felé repülve átrepül egy földi ellenőrző pont felett. Ettől a ponttól körbe repül, állandóan 30 fokos bedöntéssel. Az útirány eltérési kijelző áramot rögzítik, mielőtt a légijármű ezt a kört repüli, és átalakítják az attól kijelzett iránymeréshez viszonyított hiba fokokba, ami az eljárás kezdetén volt, amikor a légijármű az ellenőrző pont felett volt. A légijármű irányának a VOR berendezéshez viszonyított iránymérési változását le kell vonni az útirány eltérési hibából. Az eredmény, miután a vevő hibát levonták, az elfogadott polarizációs hiba.

3.3.6 A polarizációs ellenőrzések elvégzésére megfelelő a 300 méteres (1 000 láb) magasság. A 3.3.4 és 3.3.5 pontban megadott légi ellenőrzéseket egy olyan ellenőrző ponthoz viszonyítva lehet elvégezni, amely körülbelül 34,4 km-re (18 tenger mérföld) van a VOR berendezéstől.

3.4 A VOR típusú berendezések földrajzi elkülönítési követelményei

3.4.1 Az alábbi C-3. táblázatban felsorolt értékek alkalmazásánál meg kell jegyezni azt, hogy ezek meghatározott magasságokra elfogadott összefüggésekből kerültek levezetésre. Az értékek alkalmazásánál a körzeti értekezletek csak addig a mértékig adnak védelmet, ameddig üzemeltetésileg szükséges magasságban és távolságban - a képletek alkalmazásával - a követelményeket bármilyen távolságra, vagy magasságra ki lehet számítani.

3.4.2 A táblázatba foglalt számok azzal az alapfeltétellel kerültek kiszámításra, hogy a légijármű fedélzeti vevő effektív szomszédos csatorna-szűrése 60 dB-nél jobb lefelé, a következő kijelölhető csatorna felé.

3.4.3 A számítások azon az alapfeltételen alapulnak, hogy megkívánt jelnek a nem-kívánt jel interferenciájával szembeni biztosított védelme 20 dB, ami megfelel egy, a nem-kívánt jel miatti 1 foknál kevesebb iránymérési hibának.

3.4.4 Ismert az, hogy a szomszédos csatornán történő üzemelés esetében van a VOR berendezés közelében egy olyan kis terület, amelyen belül az egy másik VOR berendezést felhasználó légijármű interferenciát idézhet elő. Azonban ennek a területnek a szélessége olyan kicsi, hogy az interferencia időtartama elhanyagolható, és a legtöbb esetben ez akkor várható, amikor a légijármű az egyik berendezésről a másikra fog átkapcsolni.

C-3. táblázat: A földrajzi elkülönítési távolságok értékei közös csatornájú üzemeltetésekre

		Egyenlő kisugárzott teljesítményű VOR berendezésekre		A kisugárzott teljesítményben 6 dB-el eltérő VOR berendezésekre				A kisugárzott teljesítményben 12 dB-el eltérő VOR berendezésekre			
		Min. földrajzi elkülönítés a berendezések között $2D_1 + \frac{20}{S}$ *ha* $D_1 > D_2$ vagy $2D_2 + \frac{20}{S}$ *ha* $D_2 > D_1$		Minimális földrajzi elkülönítés a berendezések között $2D_1 + \frac{20-K}{S}$ *ha* $D_1 > D_2 + \frac{K}{S}$ vagy $2D_2 + \frac{20+K}{S}$ *ha* $D_1 < D_2 + \frac{K}{S}$				Minimális földrajzi elkülönítés a berendezések között $2D_1 + \frac{20-K}{S}$ *ha* $D_1 > D_2 + \frac{K}{S}$ vagy $2D_2 + \frac{20+K}{S}$ *ha* $D_1 < D_2 + \frac{K}{S}$			
Magasság m (láb)	S dB/km (dB/tmf)	K dB	$\frac{20}{S}$ km (tmf)	K dB	$\frac{K}{S}$ km (tmf)	$\frac{20-K}{S}$ km (tmf)	$\frac{20+K}{S}$ km (tmf)	K dB	$\frac{K}{S}$ km (tmf)	$\frac{20-K}{S}$ km (tmf)	$\frac{20+K}{S}$ km (tmf)
1	2	3	4	5	6	7	8	9	10	11	12
1 200 (4 000)	0,32 (0,60)	0	61 (33)	6	19 (10)	43 (23)	80 (43)	12	37 (20)	24 (13)	98 (53)
3 000 (10 000)	0,23 (0,43)	0	87 (47)	6	26 (14)	61 (33)	113 (61)	12	52 (28)	35 (19)	137 (74)
4 500 (15 000)	0,18 (0,34)	0	109 (59)	6	33 (18)	76 (41)	143 (77)	12	67 (36)	44 (24)	174 (94)
6 000 (20 000)	0,15 (0,29)	0	128 (69)	6	39 (21)	89 (48)	167 (90)	12	78 (42)	52 (28)	206 (110)
7 500 (25 000)	0,13 (0,25)	0	148 (80)	6	44 (24)	104 (56)	193 (104)	12	89 (48)	59 (32)	237 (128)
9 000 (30 000)	0,12 (0,23)	0	161 (87)	6	48 (26)	113 (61)	209 (113)	12	96 (52)	65 (35)	258 (139)
12 000 (40 000)	0,10 (0,19)	0	195 (105)	6	59 (32)	135 (73)	254 (137)	12	119 (64)	78 (42)	311 (168)
18 000 (60 000)	0,09 (0,17)	0	219 (118)	6	65 (35)	154 (83)	284 (153)	12	130 (70)	87 (47)	348 (188)

3.4.5 A földrajzi elkülönítés kiszámításához elfogadott képletek a következők (a tengeri mérföld értékek is behelyettesíthetők a kilométer helyére):

A — *minimális földrajzi elkülönítés (azonos csatorna):*
vagy

$$2\,D_1 + \frac{20-K}{S}\ \text{km}$$

ahol:

$$D_1 > D_2 + \frac{K}{S}$$

vagy

$$2\,D_2 + \frac{20+K}{S}\ \text{km}$$

ahol:

$$D_1 < D_2 + \frac{K}{S}$$

B — *földrajzi elkülönítés (szomszédos csatorna):*

az azonos telepítési hely esete:

$$< \frac{40-K}{S}$$

a nem-azonos telepítési hely esete:

$$> 2D_1 - \frac{40+K}{S}\ km$$

ahol:

$$D_1 > D_2 + \frac{K}{S}$$

vagy

$$2D_2 - \frac{40-K}{S}\ km$$

ahol:

$$D_1 < D_2 + \frac{K}{S}$$

C — *földrajzi elkülönítés (szomszédos csatorna)*
(100 kHz-es csatorna-osztással tervezett vevők 50 kHz-es csatorna-osztású környezetben)

Ha 26 dB-nél nem jobb effektív szomszédos csatorna szűrésű berendezést használnak (azaz egy 100 kHz-es vevőt egy 50 kHz-es környezetben), akkor a 6. számot kell behelyettesíteni a 40. szám helyére a fenti szomszédos csatorna képletbe. Ebben a példában a földrajzi azonos telepítési hely képlet nem használható, mivel a biztosított védelem határértékű lehet.

Ez a következő képlethez vezet:

$$> 2D_1 + \frac{6+K}{S}\ km$$

ahol:

$$D_1 > D_2 + \frac{K}{S}$$

vagy

$$2D_2 - \frac{6-K}{S}\ km$$

ahol:

$$D_1 < D_2 + \frac{K}{S}$$

A fenti képletekben:

D_1, D_2 = a két berendezés szükséges szolgálati távolsága (km).

K = az az arány (dB), amivel a D_1 fedésterületet biztosító berendezés kisugárzott teljesítménye meghaladja a D_2 fedésterületet biztosító berendezését.

Megjegyzés. - Ha a D_2 fedésterületet biztosító berendezés nagyobb kisugárzott teljesítményű, akkor a "K"-nak negatív értéke lesz.

S = az állandó magasság melletti távolsággal szemben a térerősséget mutató görbe lejtése (dB/km).

3.4.6 A C-3. táblázatban felsorolt számjegyek olyan környezeti feltételek biztosítására alapultak, amelyeken belül a fedélzeti vevők pontosan tudnak működni.

3.4.6.1 Az 50 kHz-es csatorna-osztással való működésre tervezett VOR vevők védelmének céljára minimális elkülönítési távolságok kerültek meghatározásra azzal a céllal, hogy a következő minimális jelviszonyokat biztosítsák a szolgálati területen belül:

a) a megkívánt jel 20 dB-el, vagy többel haladja meg a nem-kívánt azonos csatorna jelet;

b) egy nem-kívánt jel 50 kHz távolságban a megkívánt jeltől, legfeljebb 34 dB-el haladja meg a megkívánt jelet;

c) egy nem-kívánt jel 100 kHz távolságban a megkívánt jeltől, legfeljebb 46 dB-el haladja meg a megkívánt jelet;

d) egy nem-kívánt jel 150 kHz és nagyobb távolságban a megkívánt jeltől, legfeljebb 50 dB-el haladja meg a megkívánt jelet.

3.4.6.2 A 100 kHz-es csatorna-osztással való működésre tervezett VOR vevők védelmének céljára minimális elkülönítési távolságok kerültek meghatározásra azzal a céllal, hogy a következő minimális jelviszonyokat biztosítsák a szolgálati területen belül:

a) a megkívánt jel 20 dB-el, vagy többel haladja meg a nem-kívánt azonos csatorna jelet;

b) egy nem-kívánt jel 50 kHz távolságban a megkívánt jeltől, legfeljebb 7 dB-el haladja meg a megkívánt jelet;

c) egy nem-kívánt jel 100 kHz távolságban a megkívánt jeltől, legfeljebb 46 dB-el haladja meg a megkívánt jelet;

d) egy nem-kívánt jel 150 kHz és nagyobb távolságban a megkívánt jeltől, legfeljebb 50 dB-el haladja meg a megkívánt jelet.

3.4.7 A fenti 3.4.6 pontban megadott számok használata, vagy más távolságoknak és magasságoknak megfelelő számok alkalmazása magába foglalja annak az alapfeltételnek az elismerését, amit az a behelyettesítés jelent, hogy ez az elkülönítési távolságok kiszámításának egy megközelítő módszere, és a számok alkalmazása csak az alapfeltételként felállított korlátozások között lesz pontos. Az alapfeltétel magába foglalja azt, hogy a térerősségnek a távolsággal történő változása ("S" tényező) a különböző vételi magasságokon csak a VOR feletti körülbelül 5 fokos magassági szögig és a rádió rálátási vonalban érvényes. Ha a frekvencia-zsúfolt területeken az elkülönítési távolságok jóval pontosabb meghatározása szükséges, akkor azt az egyes berendezésekre a megfelelő terjedési görbékkel lehet meghatározni.

3.4.8 Az 50 kHz-es csatorna-osztású elrendezés szükségessé teszi a 3. Fejezet 3.3.2.2 és 3.3.5.7, valamint az Annex 10 V. Kötete 4. Fejezetének 4.2.4 pontjában leírtak teljesítését. Ahol különleges körülmények miatt a 100 kHz-es csatorna-osztásról az 50 kHz-es csatorna-osztásra történő átállás kezdeti periódusában alapvetően fontos az olyan közeli VOR berendezések figyelembevétele, amelyek nem felelnek meg a 3. Fejezet 3.3.2.2 és 3.3.5.7 pontjában és az Annex 10 I. Kötet 4. Fejezetének 4.2.4 pontjában leírtaknak, ott ezek és az új, az 50 kHz-es csatorna-osztású berendezések között nagyobb földrajzi elkülönítésre lesz szükség annak biztosításához, hogy a nem-kívánt jel által okozott iránymérési hiba egy foknál kevesebb legyen. Azzal az alapfeltétellel, hogy az ilyen berendezések által kisugárzott jel
9 960 Hz-es oldalsáv szintjeinek harmonikus hullámai nem haladják meg a következő szinteket:

9 960 Hz	0 dB referencia
2. harmonikus	-20 dB
3. harmonikus	-30 dB
4. harmonikus és felette	-40 dB

a fenti 3.4.5 pontban megadott elkülönítési képleteket kell alkalmazni a következők szerint:

a) ahol csak az 50 kHz-es csatorna-osztásra tervezett vevők részére kell védelmet biztosítani, ott a 40-es számot a 20-ra kell kicserélni a "B" képletben a nem-azonos telepítésű helyzetnél;

b) ahol az szükséges, hogy védelmet biztosítsanak a 100 kHz-es csatorna-osztásra tervezett vevők részére, ott az "A" alatt lévő azonos csatorna képletet kell alkalmazni az azonos csatorna helyzetre, arra a magassági tartományra, amelyre a védelem szükséges.

3.4.9 Amikor DME / N berendezéseket és VOR berendezéseket kívánnak egymással társítva üzemeltetni a 3. Fejezet 3.5.3.3.5 pontjában leírtak szerint, és azoknak azonos a szolgáltatási területe, ott a DME részére szükséges mindkét, az azonos csatorna és a szomszédos csatorna földrajzi elkülönítési követelményt kielégítő az ebben a részben a VOR-ra megadott számítások szerinti elkülönítés, feltéve azt, hogy a VOR és a DME közötti távolság nem haladja meg a 600 métert (2 000 láb).
Azonban, ha DME / W berendezést alkalmaznak, akkor az első szomszédos csatorna minimális elkülönítési távolságnak a DME / W berendezésekre egyenlőnek kell lenni a VOR azonos csatornára meghatározott elkülönítési távolsággal. A második szomszédos csatorna minimális elkülönítési távolságnak a DME / W berendezésekre egyenlőnek kell lenni a VOR-ra meghatározott első

szomszédos csatorna elkülönítéssel. Egy lehetséges interferencia helyzet fordulhat elő a DME "Y" csatornák használata esetén, mivel két, egymástól 63 MHz-re elkülönített DME földi állomás között interferencia fordulhat elő, amikor azonos frekvencián adnak és vesznek (például a 17 Y csatornától eredő adások interferenciát okozhatnak a 80 X és 80 Y csatornák vételénél). Bármilyen földi vevő érzékenységi csökkentésének elkerülésére a berendezések között minimum 18,5 km (10 tengeri mérföld) földi elkülönítési távolság szükséges.

3.5 A VOR / ILS berendezések földrajzi elkülönítési követelményei

3.5.1 A következőkben, a 3.5.3.1 és a 3.5.3.2 pontban megadott számok alkalmazásánál nem szabad megfeledkezni arról, hogy a következő alapfeltételek kerültek elfogadásra:

a) az iránysáv vevő jellemzői azok, amelyek a korábbi 2.6.2 pontban kerültek megadásra, és a VOR vevő jellemzői azok, amiket a fenti 3.4.2 pont ír elő;

b) a védettség az ILS rendszerre és a VOR rendszerre 20 dB, a korábbi 2.6.3 és 3.4.3 pontokban megadottak szerint külön-külön;

c) az ILS védettségi pontja a felhasználási vonalon mért 46,25 km-es (25 tengeri mérföld) szolgáltatási távolságban az 1 900 m-es (6 250 láb) magasságú pontban van.

Megjegyzés. - Az erősen irányított ILS iránysáv adó antenna-rendszerek megjelenésével a legkritikusabb védelmi pont nem a futópálya meghosszabbított középvonalán lesz. Az irányított antennák következtében a kritikus védelmi pontok a maximális távolságnál, a futópálya középvonalától vagy plusz, vagy mínusz 10 fokra, vagy plusz, vagy mínusz 35 fokra lesznek. Ezeknek a pontoknak a védelmét kell megvizsgálni a frekvencia kijelölési folyamat során.

3.5.2 Jóllehet, nemzetközi VOR és ILS berendezések nem fognak ugyanazon a frekvencián megjelenni, előfordulhat az, hogy egy nemzetközi VOR berendezés fogja ideiglenesen megosztani ugyanazt a frekvenciát, és hasonló alapon, egy nemzeti ILS berendezéssel. Ezért az útmutató anyag úgy került megadásra, hogy tartalmazza nemcsak az 50 kHz-es, vagy 100 kHz-es elkülönítésű VOR-ra és az ILS berendezésre, hanem azonos csatorna alkalmazására szükséges földrajzi elkülönítést is.

3.5.3 A két berendezés felhasználásának eltérő jellegzetességei miatt, a közös interferencia elkerülésére a VOR / ILS minimális földrajzi elkülönítésének követelményét, ahol az vonatkozó, különállóan kell megállapítani.

3.5.3.1 *Azonos csatorna esetén*

a) Az ILS rendszer védelme megkívánja azt, hogy egy 17 dBW (50 W) kisugárzott teljesítményű VOR legalább 148 km (80 tenger mérföld) távolságra legyen az ILS védelmi pontjától.

b) Avval az alapfeltétellel, hogy egy 17 dBW (50 W) kisugárzott teljesítményű VOR-nak a védelme a 46,25 km-es (25 tenger mérföld) szolgáltatási távolságig és a 3 000 méteres (10 000 láb) magasságig biztosítva legyen, a VOR rendszer védelme azt kívánja meg, hogy az ILS legalább 148 km-re (80 tengeri mérföld) legyen a VOR-tól.

c) Ha a VOR védelme, mondjuk, 92,5 km-ig (50 tengeri mérföld) és 6 000 m-ig (20 000 láb) szükséges, akkor az ILS-nek legalább 250 km-re (135 tengei mérföld) kell lenni a VOR-tól.

3.5.3.2 *A szomszédos csatorna esetén.* A VOR rendszer védelme a berendezések földrajzi elkülönítése nélkül hatékonyan biztosítható. Azonban, ebben az esetben:

a) ha egy olyan iránysáv vevőt használnak, amely 100 kHz-es csatorna-osztásra tervezett, és egy olyan területen, ahol a navigációs berendezések kijelölt osztása 100 kHz-es, az ILS rendszer védelme azt kívánja, hogy egy 17 dBW (50 W) kisugárzott teljesítményű VOR legalább 9,3 km-re (5 tenger mérföld) legyen az ILS védelmi pontjától;

b) ha egy olyan iránysáv vevőt használnak, amely 100 kHz-es csatorna-osztásra tervezett, és egy olyan területen, ahol a navigációs berendezések kijelölt osztása 50 kHz-es, az ILS rendszer védelme azt kívánja, hogy egy 17 dBW (50 W) kisugárzott teljesítményű VOR legalább 79,6 km-re (43 tenger mérföld) legyen az ILS védelmi pontjától.

3.5.4 A fenti 3.5.3 pontban megadott számok használata, vagy más távolságoknak és magasságoknak megfelelő számok alkalmazása magába foglalja annak az alapfeltételnek az elismerését, amit az a behelyettesítés jelent, hogy az az elkülönítési távolságok kiszámításának egy megközelítő módszere, és a számok alkalmazása csak az alapfeltételként felállított korlátozások között lesz pontos. Ha a frekvencia-zsúfolt területeken az elkülönítési távolságok jóval pontosabb meghatározása szükséges, akkor azt az egyes berendezésekre a megfelelő terjedési görbékkel lehet meghatározni.

3.5.5 Az ILS rendszernek a VOR interferenciája elleni védelme szükséges ott, ahol a VOR berendezés egy ILS megközelítési útvonal közelében kerül telepítésre. Az ilyen esetekben az ILS vevő kimeneten a lehetséges keresztmodulációs hatások miatti zavaró jel elkerülése érdekében az ILS és a VOR csatorna frekvenciái között megfelelő frekvencia elkülönítést kell alkalmazni. A frekvencia elkülönítés a VOR és az ILS teljesítmény-sűrűség arányának és a fedélzeti berendezések jellemzőinek függvénye lesz.

3.6 Vételi funkció

3.6.1 *Érzékenység.* Miután a légijármű fedélzeti tápvonal illesztést, a csillapítási veszteséget és az antenna polárgörbéjének eltéréseit megfelelően figyelembe vették, a vételi funkció érzékenységének olyannak kell lenni, hogy az esetek nagy százalékában biztosítsa az alábbi 3.6.2 pontban meghatározott kimeneti pontosságot egy olyan jelnél, amelynek a térerőssége 90 mikrovolt/méter, vagy mínusz 107 dBW/m^2.

3.6.2 *Pontosság.* A fedélzeti berendezés hiba hozzájárulása nem haladhatja meg a plusz, vagy mínusz 3 fokot egy 95 százalékos valószínűséggel.

1. Megjegyzés. - A vevő hiba hozzájárulásának értékelésénél számításba kell venni:

1) a földi VOR berendezés modulációs összetevőjének tűréshatárát, ahogy azt a 3. Fejezet 3.3.5 pontja meghatározza;

2) a földi VOR berendezés jel szintjének és vivőhullám frekvenciájának eltérését;

3) a nem-kívánt VOR és ILS jelek hatását.

2. Megjegyzés. - A légijármű fedélzeti VOR berendezésnél nincs figyelembe véve semmilyen olyan speciális rendszer beépítése, amelyet a légijármű fedélzeten a VOR információ feldolgozásához biztosítani lehet, és amely önmaga is bevihet hibákat a rendszerbe (például: a rádiómágneses irányszög kijelző (RMI) stb.).

3.6.3 *A zászló riasztás működése.* Ideálisan a zászló riasztásnak kell figyelmeztetnie a légijármű vezetőjét bármilyen olyan elfogadhatatlan működési hibáról, ami vagy a földi, vagy a fedélzeti berendezésekben előfordulhat. Az a mérték, amennyire ezt az ideális helyzetet ki lehet elégíteni, az alábbiakban kerül meghatározásra.

3.6.3.1 A zászló riasztási mozgást két áram összege hozza működésbe, azok, amelyek a VOR iránymérési összetett jel 30 Hz-es és 9 960 Hz-es elemeiből származnak, ennek megfelelően ezeknek az összetevőknek a kisugárzott vivőhullámról való eltávolítása a zászlók megjelenését eredményezi. Mivel a VOR földi felügyelő rendszere megszakítja az iránymérési összetevő sugárzását akkor, amikor bármilyen elfogadhatatlan körülmény lép fel a földön, azonnal kijelzés lesz a légijárművön, amint a rendszer használhatatlan.

3.6.3.2 A zászló riasztó mozgató áram még a fedélzeti berendezés automatikus erősítés-szabályzásának és a vevő második detektor fokozatát követő bármilyen erősítésnek is függvénye. Ennek megfelelően egy pontosan beállított fedélzeti vevőnél a zászló éppen akkor válik nem-láthatóvá, amikor egy, a 3. Fejezet 3.3.5 pontjában meghatározott modulációs jellemzőknek megfelelő VOR jel kerül vételre, és abban az esetben lesz újra látható, amikor csökkenés következik be a vevő teljes erősítési jellemzőiben.
Megjegyzés. - Bizonyos vevő típusoknál a mechanikus zászlótól eltérő egyéb figyelmeztető jelzést alkalmaznak az itt leírt funkció végrehajtására.

3.6.4 *A VOR vevőnek a VOR és az iránysáv jelekre való érzékenysége*

3.6.4.1 A vevő felépítésének biztosítani kell annak pontos működését a következő környezetben:

a) amikor a megkívánt jel a nem-kívánt azonos csatornájú jelet 20 dB-el, vagy többel meghaladja;

b) amikor a megkívánt jeltől 50 kHz távolságban a nem-kívánt jelet 34 dB-nek megfelelő értékkel meghaladja (a vevőnek a próbapadi ellenőrzése során ebben az első szomszédos csatorna esetben a nem-kívánt jel a kombinált földi állomás frekvencia-tartománya felett (plusz, vagy mínusz 9 kHz) és a frekvencia tűréshatárban változik);

c) amikor egy nem-kívánt jel a megkívánt jeltől 100 kHz távolságban 46 dB-nek megfelelő értékkel meghaladja a megkívánt jelet;

d) amikor egy nem-kívánt jel a megkívánt jeltől 150 kHz, vagy annál nagyobb távolságban 50 dB-nek megfelelő értékkel meghaladja a megkívánt jelet.

1. Megjegyzés. - Elfogadott az, hogy nem az összes, jelenleg használatos vevő felel meg a b) alpont követelményeinek, az összes jövőben használatba kerülő berendezést úgy kell megépíteni, hogy eleget tegyenek ennek a követelménynek.

2. Megjegyzés. - Néhány Államban kisebb földi állomás tűréshatárokat alkalmaznak.

3.6.5 *A VOR vevő rendszer érzéketlenségi teljesítménye a VHF FM adások jeleinek zavaró hatásával szemben*

3.6.5.1 A 3. Fejezet 3.3.8 pontjának megjegyzéseire vonatkozóan, az ott meghatározott érzéketlenségi teljesítményt a vevő rendszer szabályos teljesítményéhez viszonyított egyezményes csökkenési mértékhez kell venni a bemenő megkívánt jel szabvány körülményei mellett és jelenlétében. Ez annak biztosításához szükséges, hogy a vevő berendezésnek a próbapadi ellenőrzését egy ismételhető feltétel-rendszer és eredmények mellett lehessen elvégezni, ami elősegítse az azt követő hitelesítési jóváhagyásukat. Vizsgálatok kimutatták azt, hogy az FM interferencia jelek hatással lehetnek mind az irányvezetési, mind a zászló áramra, és hatásuk annak a megkívánt jelnek a modulációs mélység különbségétől (DDM) függ, amit alkalmaznak. Kiegészítő tájékoztatások találhatók a Nemzetközi Távközlési Uniónak /ITU/ *A 87 - 108 MHz-es műsorszóró szolgáltatási sáv és a 108 - 118 MHz-es légiforgalmi szolgálati sáv közötti kompatibilitás meghatározására használatos vevők jellemzőinek mérési eljárásai* című, ITU-R IS.1140 számú Ajánlásában.

3.6.5.2 Általánosan elfogadott módszereket és képleteket kell alkalmazni azon vevők lehetséges összeférhetetlenségének megállapításához, amelyek megfelelnek a 3. Fejezet 3.3.8 pontjában meghatározott általános interferencia érzéketlenségi követelményeknek.
A képleteknek tisztázniuk kell a parazita sugárzással (A1 típusú) szembeni interferencia érzéketlenségi teljesítményt, a csatorna sávon kívüli (A2 típusú) interferenciával szembeni, a két-jel és három-jel harmadrendű (B1 típusú) interferenciával szembeni és a túlterhelés / érzéketlenítés (B2 típusú) interferenciával szembeni interferencia érzéketlenségi teljesítményt. Kiegészítő tájékoztatások találhatók a Nemzetközi Távközlési Uniónak /ITU/ az ITU-R IS.1009-1 sz. *Kompatibilitás a 87 - 108 MHz-es műsorszóró szolgáltatási sáv és a 108 - 137 MHz-es légiforgalmi szolgálati sáv között* tárgyú Ajánlásban.

3.6.5.3 A Nemzetközi Távközlési Unió /ITU/ ITU-R IS.1009-1 Ajánlásában megadott frekvencia tervezési követelmények nem veszik számításba a lehetséges két-jel és három-jel ötödrendű intermodulációs termékeket. Mérésekkel határozták meg azt, hogy az FM állomások által a vevőkben létrehozott ötödrendű intermodulációs termékek úgy lecsökkenthetik a VOR vevők teljesítményét, hogy az a 3. Fejezet 3.3.8 pontjában leírt meghatározásoknak felel meg. Az ötödrendű intermodulációs termékek előfordulhatnak anélkül, hogy egy harmadrendű intermodulációs termék fordulna elő ugyanazon a VOR frekvencián. A frekvenciák tervezésében és az FM műsorszóró interferenciája elleni védelem felbecsülésénél szükség van arra, hogy figyelembe vegyék a két-jel és három-jel által létrehozott ötödrendű intermodulációs termékeknek a VOR vevőkön belül létrehozott termékeit.

3.7 A VOR rendszer pontossága

Megjegyzés. - A VOR rendszer teljesítmény értékeinek meghatározására vonatkozó útmutató anyagot foglal magába még az Annex 11 "A"- Melléklete is.

3.7.1 *Cél.* Az alábbi tájékoztató anyag célja az, hogy segítséget nyújtson a VOR rendszerek felhasználásához. Nem az a cél, hogy bemutassa az oldalirányú elkülönítési szabványokat, vagy a minimális akadálymentességet, jóllehet, ezek is természetesen kiindulási pontot adnak azok meghatározásában. Az elkülönítési szabványok, vagy a minimális akadálymentességek meghatározásánál szükségszerűen számításba kell venni még több olyan tényezőt, amellyel az alábbi anyag nem foglalkozik.

3.7.1.1 Azonban szükséges az, hogy egy rendszer-felhasználási pontossági számot közöljünk az Államokkal, útmutatóként a VOR rendszerek tervezéséhez.

3.7.2 *A szakkifejezések magyarázata.* A következő szakkifejezéseket az itt megadott jelentésekkel használjuk:

a) ***VOR radial signal error.*** *VOR radiál jelhiba.* A földi VOR állomástól egy mérési pontig mért névleges mágneses iránymérés és a VOR jel által az ugyanarra a pontra kijelzett iránymérés közötti különbség. A VOR radiál jelhiba bizonyos állandó elemekből tevődik össze, mint például az útirány eltolódási hibából, valamint a telepítési hely és terepfelszín hatások következtében előforduló hibákból, továbbá bizonyos rendszertelenül változó hibákból. A VOR radiál jelhiba csak a földi állomáshoz kapcsolódik, és kizárja az egyéb hiba- tényezőket, azaz például a légijármű fedélzeti berendezés hibáit és a vezetési pontatlanságot.

b) ***VOR radial variability error.*** *VOR radiál változékonysági hiba.* A VOR radiál jelhibájának az a része, ami várhatóan változik egy alapvetően állandó hibatag körül. A radiál változékonysági hiba a változó hibák összege.

c) ***VOR radial displacement error.*** *VOR radiál eltolódási hiba.*
A VOR radiál jelhibájának az a része, amely állandó, és amelyet egy hosszú időtartamra változatlannak lehet tekinteni.

d) ***VOR airborne equipment error.*** *VOR fedélzeti berendezés hiba.* A légijármű fedélzetén lévő berendezés azon képessége hiányának tulajdonítható hiba, hogy a radiál jelben lévő iránymérési információt pontosan továbbítsa. Ez a hiba magába foglalja a fedélzeti vevőkészülék és a légijárművezető részére az információk megjelenítésére felhasznált műszerek hiba hozzájárulását.

e) ***VOR aggregate error.*** *VOR egyesített (kummulatív) hiba.* A földi VOR állomástól egy mérési pontig mért mágneses iránymérés és a fedélzeti VOR berendezés által a meghatározott pontossággal kijelzett iránymérés közötti különbség. Jóval egyszerűbben megfogalmazva az az abban az információban lévő hiba, ami a légijárművezető előtt megjelenítésre kerül, amiben számításba van véve nemcsak a földi berendezés és a terjedési út hibája, hanem azok a hibák is, amelyeket a légijármű fedélzeti VOR vevő és a repülőgép műszerei adnak hozzá a hibához. A teljes VOR radiál jelhiba, mind az állandó, mind a változó használatos itt.

f) ***VOR pilotage element.*** *VOR légijárművezetői hibaelem.* A VOR navigációs felhasználásával az annak a ténynek tulajdonítható hiba, hogy a légijármű vezetője vagy nem tartja, vagy nem képes pontosan a légijárművet a VOR radiálon, vagy a részére kijelzett iránymérésen tartani.

g) ***VOR system use error.*** *A VOR rendszer felhasználási hibája.*
A VOR egyesített hiba és a légijárművezetői hiba négyzetes középértéke. Ezt a kombinációt lehet annak a valószínűségnek a meghatározására felhasználni, hogy egy, a VOR-t felhasználó légijármű meddig marad egy előírt tűréshatáron belül.

3.7.3 *A VOR rendszer felhasználási pontosságának meghatározása*

3.7.3.1 A VOR rendszer felhasználási pontossága a következő hibaelemek figyelembevételével kerül levezetésre:

a) *VOR radiál jelhiba* (Eg). Ezt az elemet a VOR radiál eltolódási hiba és a radiál változékonysági hiba alkotja. Ezt az olyan tényezők figyelembevételével lehet meghatározni, mint a változatlan radiál eltolódás, az ellenőrzés, a polarizációs hatások, a terepfelszín hatásai és a környezet-változások.

b) *VOR fedélzeti berendezés hiba* (Ea). Ez az elem magába foglalja a fedélzeti VOR rendszer összes olyan tényezőjét, amelyek hibát eredményezhetnek (az egyes VOR kijelzőkön megjelenített iránytű információk alkalmazásából eredő hibák nincsenek figyelembevéve).

c) *A VOR légijárművezetői hibaeleme* (Ep). Az erre a hibaelemre alkalmazott értékek azok, amelyek a PANS-OPS-ban (Doc 8168) légijárművezetői tűréshatárként kerülnek alkalmazásra.

Megjegyzés. - Fennáll még egy mérési hiba is, de a hibák általános tárgyalásánál ez úgy tekinthető, mint egy, a többi hiba értékében eloszló hiba.

3.7.3.2 Mivel amikor az a), b) és c) pontokban lévő hibákat rendszer alapon (nem pedig bármelyik adott radiálra) veszik figyelembe, akkor azok független változók, ezért azokat a négyzetes középérték (RSS) módszerével lehet összekapcsolni akkor, amikor ugyanazt a valószínűségi szintet adják minden egyes elemnek. Ezen anyag céljára az egyes elemek 95 százalékos valószínűséggel lettek figyelembevéve.

Ennek megfelelően a következő képleteket kapjuk:

VOR egyesített hiba =

$\sqrt{Eg^2 + Ea^2}$

VOR rendszer felhasználási hiba =

$\sqrt{Eg^2 + Ea^2 + Ep^2}$

3.7.3.3 A következő példák csak a VOR rendszer hibáját adják meg, de a számításokat el lehet végezni a VOR egyesített hiba meghatározására is, ha úgy kívánják. Ezeknek a képleteknek az alkalmazásával meg lehet állapítani egy, vagy több hibaelem növekedésének, vagy csökkenésének a rendszerre gyakorolt hatását.

Megjegyzés. - A VOR radiál jelhibával kapcsolatos valamennyi érték azokra a radiálokra vonatkozik, amelyekre semmilyen korlátozást nem tettek közzé.

3.7.3.4 A fenti 3.7.1 pontban jelzett fenntartással úgy gondoljuk, hogy egy VOR rendszer felhasználási pontosságára a 95 százalékos valószínűségi alapon a plusz, vagy mínusz 5 fok elfogadható számérték az Államok részére a VOR rendszerek alkalmazásának tervezésénél (lásd még az alábbi 3.7.3.5 pontot). Ez a szám a következő hiba összetevőknek felel meg:

VOR radiál jelhiba:
a plusz, vagy mínusz 3°-os érték (95 százalékos valószínűséggel), a gyakorlatban könnyen elérhető.

VOR légijármű fedélzeti berendezés hiba:
plusz, vagy mínusz 3° (95 százalékos valószínűséggel), rendszer jellemző érték (lásd a fenti 3.6.2 pontot).

VOR légijárművezetői hibaelem:
plusz, vagy mínusz 2,5° (95 százalékos valószínűséggel), a PANS-OPS-nak megfelelően (lásd még az alábbi 3.7.3.8 pontot).

3.7.3.5 Míg a 95 százalékos valószínűségi alapú plusz, vagy mínusz 5 fokos érték egy olyan használható érték, amely széleskörű gyakorlati tapasztalatokon alapul, és sok Államban alkalmazzák, meg kell jegyezni, hogy ezt az értéket csak akkor lehet elérni, ha azok a hibaelemek, amelyek ezt létrehozzák, meghatározott tűréshatárokon belül maradnak. Nyilvánvaló az, hogyha a VOR rendszer elemeknek tulajdonítható hiba nagyobb a leírt értékeknél, akkor a létrejövő VOR rendszer felhasználási hiba ugyancsak nagyobb lesz. Ennek ellentétéként, ahol valamelyik, vagy az összes VOR rendszer hibaelem kisebb annál, mint ami a fenti számításban alkalmazva volt, a létrejövő VOR rendszer felhasználási hiba ugyancsak kisebb lesz.

3.7.3.6 A következő példák - amelyek ugyancsak gyakorlati tapasztalatokból erednek - kiegészítő tervezési útmutatóként szolgálnak az Államok részére:

A - *VOR radiál jelhiba:*
Plusz, vagy mínusz 3,5° (95 százalékos valószínűséggel), ezt néhány Államban teljes földi rendszer hibaként használják.

VOR fedélzeti berendezés hiba:
plusz, vagy mínusz 4,2° (95 százalékos valószínűséggel), amit néhány Állam minimális teljesítmény értékként az üzemeltetések bizonyos osztályaira elfogad.

VOR légijárművezetői hibaelem:
plusz, vagy mínusz 2,5° (95 százalékos valószínűséggel), a PANS-OPS előírásaival megegyezően (lásd még az alábbi 3.7.3.8 pontot).

Számított VOR rendszer felhasználási pontosság:
plusz, vagy mínusz 6° (95 százalékos valószínűséggel).

B - *VOR radiál jelhiba:*
plusz, vagy mínusz 1,7° (95 százalékos valószínűséggel), széleskörű légi ellenőrzési mérésekre alapozva, amelyet egy Államban hajtottak végre több VOR berendezés mérésével.

VOR fedélzeti berendezés hiba:
plusz, vagy mínusz 2,7° (95 százalékos valószínűséggel), sok légitársaság üzemeltetési mérései által elért érték.

VOR légijárművezetői hibaelem:
plusz, vagy mínusz 2,5° (95 százalékos valószínűséggel), a PANS-OPS előírásaival megegyezően (lásd még az alábbi 3.7.3.8 pontot).

Számított VOR rendszer felhasználási pontosság:
plusz, vagy mínusz 4° (95 százalékos valószínűséggel).

3.7.3.7 A VOR rendszer jóval valószerűbb alkalmazását lehet elérni a meghatározott körülmények között ténylegesen fennálló hibák megállapításával és nem a mindent felölelő általánosítás alkalmazásával, amely alaptalanul optimista, vagy pesszimista eredményeket adhat. Az egyedi alkalmazásoknál lehetséges lesz az, hogy a plusz, vagy mínusz 5 foknál kisebb értékű rendszer felhasználási pontossági értékeket alkalmazzanak, ha egy, vagy több hibaelem kisebb azoknál az értékeknél, amelyek a plusz, vagy mínusz 5 fokos számításhoz kerültek felhasználásra. Illetve fordítva, egy plusz, vagy mínusz 5 foknál nagyobb értékű rendszer felhasználási pontossági értékre lenne szükség akkor, amikor ismert az, hogy a radiálok gyenge minőségűek, vagy jelentős telepítési helyszíni hibák állnak fenn, illetve egyéb okok indokolják. Azonban ehhez a tanácshoz kiegészítőleg elengedhetetlenül szükséges egy figyelmeztetés a rendszer egyes, egyedüli elemeinek alacsonyabb értékei alkalmazásánál (például a radiál jelhibánál) abból az alapfeltételből kiindulóan, hogy a rendszer pontosságban egy átfogó javulás fog jelentkezni. Egyértelműen nyilvánvaló az, hogy bizonyos körülmények között az nem fordulhat elő, és nem alkalmazhatnak alacsonyabb rendszer pontossági értékeket másfajta olyan 'megerősítés' nélkül (pl. radarral való megfigyelés nélkül), amely a teljes teljesítmény tényleges növekedésének elérését igazolja.

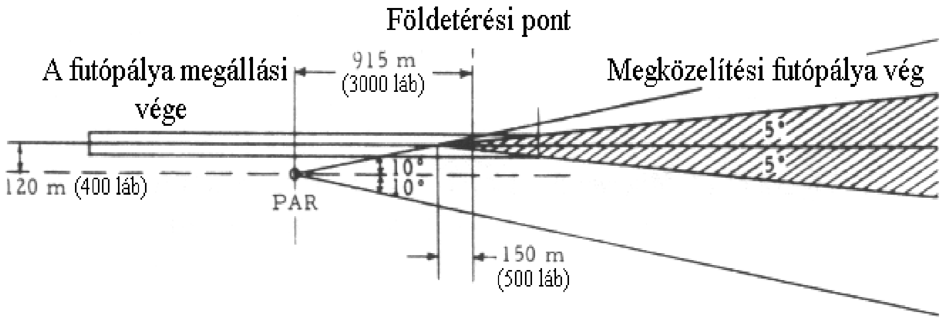
3.7.3.8 Meg kell jegyezni azt, hogy az olyan irányszögadó berendezéseknél, mint a VOR, a szög-értékben kifejezett légijárművezetői hibaelem nagyobb lesz, ahogy a légijármű közeledik az információ-forráshoz. Így, mivel a földi rendszer és a fedélzeti hiba hozzájárulása szög-értékben kifejezve az összes gyakorlati szempontból minden távolságban állandó, a rendszer általános felhasználási pontossági értékeinek figyelembevétele során számításba kell venni a nagyobb légijárművezetői hibaelem előfordulását akkor, amikor a légijármű a VOR közelében van. Azonban ezek a nagyobb légijárművezetői hibaelemek nem eredményeznek az útiránytól való nagy oldalirányú eltéréseket akkor, amikor a légijármű a berendezés közelében van.

3.8 A VOR-ok átkapcsolási pontjai

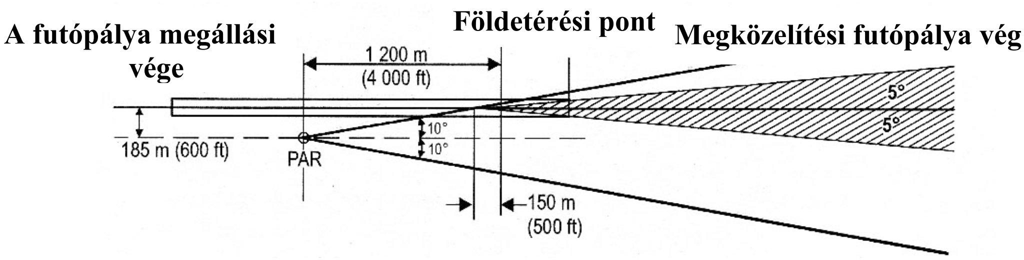
A VOR-al meghatározott ATS útvonalakon az átkapcsolási pontok meghatározására vonatkozó útmutató anyagot az Annex 11 "A"- Melléklete foglalja magába.

4. Precíziós megközelítési radar rendszer

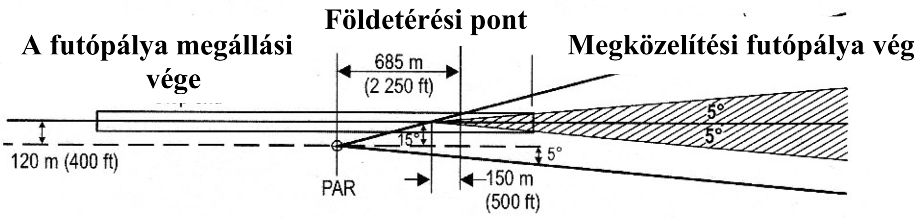
C-14.-től a C-18.-ig terjedő ábrák mutatják be a 3. Fejezet 3.2 pontjában lévő Szabványokat.



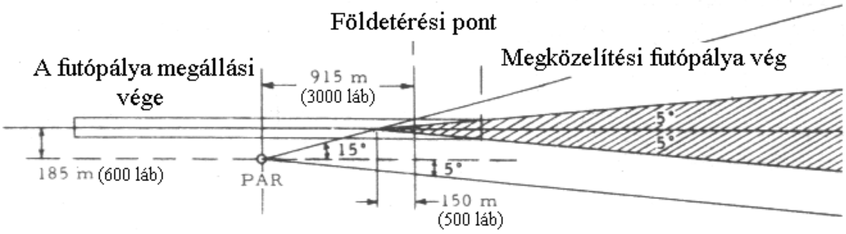
C-14. ábra: A Precíziós Megközelítési Radarnak (PAR) a földetérési ponthoz viszonyított minimális 'hátrafelé' történő elhelyezése 120 méteres (400 láb) oldalirányú eltolásos telepítésnél, amikor a letapogatás a futópályára vezető iránytól (QDR) plusz, vagy mínusz 10 fokra van beállítva



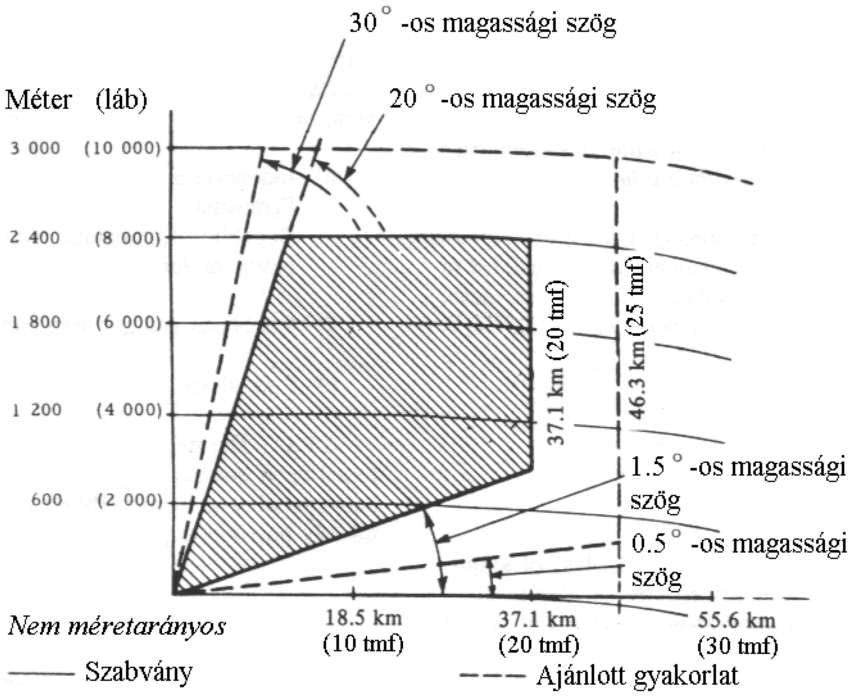
C-15. ábra: A Precíziós Megközelítési Radarnak (PAR) a földetérési ponthoz viszonyított minimális 'hátrafelé' történő elhelyezése 185 méteres (600 láb) oldalirányú eltolásos telepítésnél, amikor a letapogatás a futópályára vezető iránytól (QDR) plusz, vagy mínusz 10 fokra van beállítva



C-16. ábra: A Precíziós Megközelítési Radarnak (PAR) a földetérési ponthoz viszonyított minimális 'hátrafelé' történő elhelyezése 120 méteres (400 láb) oldalirányú eltolásos telepítésnél, amikor a letapogatás a futópályára vezető iránytól (QDR) 5 és 15 fokra van beállítva



C-17. ábra: A Precíziós Megközelítési Radarnak (PAR) a földetérési ponthoz viszonyított minimális 'hátrafelé' történő elhelyezése 185 méteres (600 láb) oldalirányú eltolásos telepítésnél, amikor a letapogatás a futópályára vezető iránytól (QDR) 5 és 15 fokra van beállítva



C-18. ábra: A precíziós megközelítési radar rendszer Légtérellenőrző Radar Egysége (SRE) - függőleges fedésterület egy 15 m^2-es visszaverő felületű légijárműre

5. Előírások a 75 MHz-es (útvonal) helyjeladókra

5.1 A helyjeladó antenna-rendszerei

5.1.1 *Általános rész.* Az alábbiakban azok a helyjeladó antenna-rendszer típusok kerülnek leírásra, amelyeket a jelenlegi gyakorlatban gyakran használnak. Ezek a típusúak azok a legegyszerűbb kialakítások, amelyek a szabvány követelményeknek megfelelnek; különleges esetekben jobb teljesítményű antenna-rendszerekre (lásd az alábbi 5.1.4 pont Megjegyzését) lehet szükség.

5.1.2 *Z helyjeladók*

a) *Sugárzó rendszerűek.* A sugárzó rendszer két vízszintes, egymást derékszögben keresztező dipól-elemből áll, amelyek mindegyikét két kollineáris fél-hullámhossz sugárzó elem képezi, a középpontjukból egymástól körülbelül fél hullámhossz távolságra elhelyezve, és egy negyed hullámhosszal az ellensúly fölé felépítve. A dipólokban lévő áramokat és azok egymáshoz viszonyított elemeit úgy kell beállítani, hogy:

1) az egyik dipól-rendszerben lévő áram a másik rendszerekben lévőkhöz viszonyítva egyenlő legyen, de 90^{o}-os időbeni fáziseltolású legyen;

2) az egyedi dipól-rendszer sugárzó elemei áramainak egyenlőnek és időbeli fázisban lévőnek kell lenni.

b) *Ellensúly.* A négyszög alakú, minimálisan 9 m × 9 m-es ellensúlynak általában a földfelszín felett körülbelül 1,8 méteres (6 láb) magasságban kell lenni, és ha dróthálóból készült, akkor a hálószem 7,5 cm × 7,5 cm-t nem meghaladó méretű kell, hogy legyen.

5.1.3 *A csak kis magasságokban történő felhasználású legyező alakú sugárnyalábú helyjeladók (kis teljesítményű legyező alakú sugárnyalábú helyjeladók).* A sugárzó rendszernek képesnek kell lenni arra, hogy a 3. Fejezet 3.1.7.3.2 pontjában leírtak szerinti térerősséget biztosítsa.

5.1.4 *Általános felhasználású legyező alakú sugárnyalábú helyjeladók (nagy teljesítményű legyező alakú sugárnyalábú helyjeladók)*

a) *Sugárzó rendszer.* A sugárzó rendszer négy vízszintes kollineáris fél- hullámhosszú (körülbelül) sugárzó elemből áll, körülbelül egy-negyed hullámhosszal az ellensúly fölé felépítve. Az egyes antenna- elemekben az áramnak fázisban kell lenni és az áram-aránynak
1 : 3 : 3 : 1-nek kell lenni.

Megjegyzés. - Az antenna-elemek közötti áramelosztás és azoknak az ellensúly feletti magassága módosítható azért, hogy a különleges üzemeltetési körülményekhez sugárzási karakterisztikát biztosítson. Megnövelt függőleges sugárzási karakterisztika a meghatározott üzemeltetési igényekhez úgy érhető el, hogy szabályozzák a dipól antenna-rendszernek az ellensúly feletti magasságát az egy-negyed hullámhosszig, vagy annál magasabbra, de a fél-hullámhossznál kisebb értékre.

b) *Ellensúly.* Egy négyszög alakú ellensúlyt, minimálisan 6 × 12 méteres méretűt, általában 1,8 méterre (6 láb) a földfelszín felett kell elhelyezni, és ha dróthálóból készült, akkor a hálószemek mérete nem haladhatja meg a 7,5 cm × 7,5 cm-t.

5.2 A négy-jelsávos rádiójeladóhoz kapcsolódó helyjeladók azonosító kódolása

5.2.1 A négy-jelsávos rádiójeladók szakaszain elhelyezett legyező alakú sugárnyalábú helyjeladókhoz szabályszerűen nem szükséges az adott földrajzi helyre vonatkozó azonosító jel, csak az a jel, amely azt a szakaszt jelzi, amelyhez a helyjeladók kapcsolódnak.

5.2.2 Abban az esetben, amikor a négy-jelsávos rádiójeladónak csak egy helyjeladó van minden szakaszán elhelyezve, a jelenlegi gyakorlat az, hogy a helyjeladót az egyedüli vonással azonosítják a földrajzi Észak irányában, vagy a földrajzi Északhoz közel eső irányban és az óramutató járásával egyező irányban haladóan (Keletre) azonosítják, a további szakaszokban két, három, vagy négy vonással attól függően, hogy a szakasz, amelyhez kapcsolódik a második, harmadik, vagy negyedik szakasz az Északtól az óramutató járásával megegyező irányban. Ahol egynél több legyező alakú sugárnyalábú helyjeladó kapcsolódik a négy-jelsávos rádiójeladó egy szakaszához, ott az állomáshoz legközelebbi helyjeladót kell csak vonásokkal azonosítani, a következő legközelebbit a vonások előtt két ponttal és a harmadikat a vonásokat megelőzően három ponttal, és így tovább.

Megjegyzés. - Bizonyos különleges körülmények esetén a fenti kódolási rendszer félreérthetőséghez vezethet a földrajzilag egymáshoz közel lévő különböző, de egymást átfedő, szakaszokhoz kapcsolódó két helyjeladó miatt. Az ilyen esetekben az a kívánatos, hogy a helyjeladók esetében az egyiknek megkülönböztető azonosító kódjelet használjanak.

6. Az NDB-re vonatkozó anyag

6.1 Útmutató anyag a 30° N és 30° S szélességi körök közötti telepítésű NDB-k térerősségi követelményeihez

6.1.1 Abból a célból, hogy kielégítő szolgáltatást biztosítsanak a 30° N és 30° S szélességi körök között elhelyezett NDB-k névleges fedésterületén belül, 120 mikrovolt / méteres minimális értékű térerősség szükséges, kivéve ott, ahol az NDB-k üzemeltetése során több éven keresztül szerzett gyakorlati tapasztalatok azt mutatják, hogy a 70 mikrovolt / méteres minimális térerősség kielégítő ahhoz, hogy az üzemeltetési követelmények kielégítésre kerüljenek. Egyes különleges területeken a 120 mikrovolt / métert jelentősen meghaladó térerősségre lesz szükség. Ezek a területek:

a) Indonézia és Pápua Új-Guinea, Myanmar, Maláj félsziget, Thai- föld, Laoszi Demokratikus Népköztársaság, Kambodzsai Demokratikus Köztársaság, Vietnám és Észak-Ausztrália;

b) Karib Szigetek és Dél-Amerika északi részei;

c) Közép- és Dél-Közép Afrika.

6.1.2 A 120 mikrovolt / méter térerősség a napjainkig szerzett gyakorlati tapasztalatokon alapszik és egy kompromisszum a műszakilag kívánatos és gazdságosan még biztosítható érték között.

6.2 Útmutató anyag a névleges és a tényleges fedésterület jelentéséről és alkalmazásáról

6.2.1 Névleges fedésterület

6.2.1.1 A 3. Fejezet 3.4.1 pontjában meghatározott névleges fedésterület az NDB tényleges teljesítményének mérhető módon történő meghatározási eszköze, amely a frekvenciától, a kisugárzott teljesítménytől, valamint az NDB és a határon lévő pont közötti vezetőképességi úttól függ, ahova a térerősség minimális értéke előírásra került.

6.2.1.2 A névleges fedésterületről megállapították, hogy az egy hasznos eszköz a körzeti tervezés elősegítéséhez, és egyes esetekben a tényleges fedésterületre is vonatkoztatható.

6.2.1.3 A névleges fedésterületnek a frekvencia tervezésre történő alkalmazását a következő követelmények szabályozzák:

6.2.1.3.1 A frekvenciákat az érintett NDB-k névleges fedésterületének figyelembevételével úgy kell elrendezni, hogy bármely NDB jel erősségének aránya a névleges fedésterülete határvonalánál, az azonos csatornájú állomások és a szomszédos csatornájú állomások miatti teljes térerősségre viszonyítva (a jellemző fedélzeti vevő szelektivitás jelleggörbéjének megfelelően figyelembevéve) ne legyen 15 dB-nél kevesebb, nappal.

6.2.1.3.2 Az Annex 10 V. Kötetének "B"- Mellékletében megadott értékeket kell alkalmazni, ahogy megfelelőek, a szomszédos csatornájú jelek csillapítására figyelembe vett tűrések meghatározásánál.

6.2.1.4 A névleges fedéterületnek a frekvencia elosztási tervezésben történő alkalmazásából következik az - hacsak nincs másképpen előírva -, hogy a káros interferencia elleni védelem csak az NDB névleges fedésterületén belül biztosítható, és csak akkor, ha az NDB kisugárzott teljesítményét úgy állítják be, hogy a névleges fedésterület határán a megkívánt térerősség elfogadhatóan közeli határértékeken belül legyen biztosítva. Az olyan területeken, ahol az NDB-k telepítési sűrűsége nagy, bármely olyan NDB, amely a névleges fedésterülete határán olyan jelet ad, ami az érintett körzetre megállapodottnál jelentősen nagyobb, általában káros interferenciát fog létrehozni az érintett területeken lévő azonos csatornájú, vagy szomszédos csatornájú NDB-k névleges fedésterületén belül, és korlátozni fogja azoknak az NDB-knek a számát, amelyek a körzetben rendelkezésre álló frekvencia-tartományon belül telepíthetőek. Ennek megfelelően az a fontos, hogy a kisugárzott teljesítménynek a névleges fedésterület biztosításához szükséges értéken felülre történő növelését - különösen éjszaka, amikor a térhullámú terjedés nagy távolságban is interferenciát idézhet elő -, nem lehet végrehajtani anélkül, hogy a valószínűleg érintett további állomásokat üzemeltető hatóságokkal azt ne egyeztetnék (lásd a 3. Fejezet 3.4.3 pontját).

6.2.1.5 A frekvencia tervezést jelentős mértékben elősegíti az, ha a kívánt fedésterületen belül közös minimális térerősségi értéket használnak.

6.2.1.6 Széleskörű tapasztalatok kimutatták azt, hogy az olyan viszonylag alacsony zajszintű területeken, mint például Európa, a 70 mikrovolt / méteres érték kielégítő térerősséget ad.

6.2.1.6.1 Tapasztalatok bizonyítják azt is, hogy a 120 mikro-volt / méteres érték általában kielégítő a nagyobb zajszintű területeken, de a nagyon magas zajú területeken ez nem lesz megfelelő. Az ilyen területeken az alábbi 6.3 pontban megadott tájékoztatásokat lehet általános útmutatásként felhasználni.

6.2.2 *A tényleges fedésterülettel való összefüggés*

6.2.2.1 A névleges fedésterületnek a tényleges fedésterülettel a következő feltételek esetén lehet szoros összefüggése:

a) akkor, amikor a névleges fedésterületen belül a minimális térerősség olyan, hogy az az idő legnagyobb részében meghaladja a légköri és egyéb zajok miatti térerősséget, és kielégítő annak biztosításához, hogy az utóbbiak nem fogják torzítani a légijárműveknek biztosított tájékoztatást olyan mértékben, hogy az használhatatlan legyen;

b) akkor, amikor a megkívánt jelnek az interferáló jelekhez viszonyított térerősség aránya a fedésterületen belül minden pontban meghaladja azt a minimális szükséges értéket, ami annak biztosításához szükséges, hogy az interferáló jelek ugyancsak nem fogják olyan mértékben torzítani a légijárműveknek biztosított tájékoztatást, hogy az használhatatlan legyen.

6.2.2.2 Mivel szabályszerűen a fedésterületen belül a leggyengébb jel annak határvonalánál fog jelentkezni, azért ezek a feltételek maguk után vonják azt, hogy a térerősség a határvonalnál olyan legyen, hogy a légköri zajszintekhez viszonyított aránya használható kijelzést biztosítson a légijármű fedélzetén az idő legnagyobb részében a határvonal értékre vonatkoztatva, és az általános tervezésnek kell biztosítani azt, hogy ezen értékeknek az aránya az interferáló jelek szempontjából az idő legnagyobb részében meghaladja a kívánt értéket.

6.2.2.3 Jóllehet, a frekvencia elosztásnál használt 70 mikro-volt / méteres értéket Európában (a 30^{o}-os földrajzi szélességtől Északra) eredményesnek találták ahhoz, hogy megadja azokat a fedésterületi értékeket, amelyek az idő legnagyobb részében szorosan megközelítik a tényleges fedésterületet, túlságosan korlátozott tapasztalat áll rendelkezésre annak bizonyításához, hogy a 120 mikrovolt / méteres érték alkalmas a magas zajszintű területeken történő általános alkalmazásra. Az várható, hogy a magas zajszintű területek névleges fedésterületi határvonalain a 120 mikrovolt / méteres értéken alapuló térerősség a legtöbb esetben az elért tényleges fedésterületnél lényegesen nagyobb lesz. Az ilyen területeken a névleges fedésterület és az átlagosan elért tényleges fedésterület közötti jobb kölcsönös viszony biztosítása érdekében az lehet a tanácsos, hogy olyan határvonali értéket válasszanak meg, amely az azon a területen lévő zajnak az olyan területen lévő zajhoz való jóval közelebbi arányosságán alapszik, amelyre már kielégítő határvonali értéket határoztak meg (pl. Európa), vagy egy olyan megfelelő értéket határozzanak meg, ami egy ismert teljesítményű területen lévő NDB ténylegesen elért tényleges fedésterületének statisztikai vizsgálatából származik.

6.2.2.4 Fontos annak tisztánlátása azonban, hogy a különböző területeken fennálló zajszintek egyszerű összehasonlításán alapuló minimális térerősség értékek esetleg nem lesznek kielégítőek az olyan tényezők miatt, mint például a zaj előfordulási gyakorisága, tulajdonsága és a légijármű fedélzeti vevőberendezésére gyakorolt hatása, valamint a kapcsolódó légiforgalmi mozgások természete, amelyek mind módosíthatják az ilyen módon meghatározott arányokat.

6.2.2.5 A világ különböző részein fennálló napszaki és évszaki zaj értékeket a Nemzetközi Távközlési Unió (ITU) korábbi Nemzetközi Rádió Tanácsadó Bizottsága (CCIR) 322. Jelentése teszi közzé.

6.2.2.5.1 Ezeknek az értékeknek a tényleges helyi körülményekkel való összehasonlítása és az ADF (automatikus rádióirány kereső) berendezések eredményes üzemeltetési felhasználásához szükséges jel - zaj viszony bevezetése még nincs teljes mértékben meghatározva.

6.2.3 Tényleges fedésterület

6.2.3.1 A tényleges fedésterület - ahogy az a 3. Fejezet 3.4.1 pontjában meghatározásra került - az egy NDB-t körülvevő azon terület, amelyen belül az érintett üzemeltető felhasználható tájékoztatást kaphat egy meghatározott időben. Ez ennek megfelelően az NDB felhasználhatóságának mértéke a fennálló körülmények között.

6.2.3.2 A tényleges fedésterületet az NDB-től vett állandó (nem-elhalkuló) jel erősségének az ADF vevőkészülék által vett összes zajhoz viszonyított aránya korlátozza. Amikor ez az arány egy határérték alá csökken, akkor nem juthatnak hozzá használható irányméréshez. Azt is meg kell jegyezni, hogy egy NDB tényleges fedésterületét bizonyos esetekben a felhasználható azonosító jel adástávolsága is korlátozhatja.

6.2.3.3 Az NDB-től vett jel erősségét a következők határozzák meg:

a) az NDB antennájába betáplált teljesítmény;

b) az antenna sugárzási hatásfoka, amely az antenna magasságától és a sugárzó rendszer egyéb jellemzőitől függően változó;

c) az NDB és a vevőberendezés közötti terjedési út vezetőképesssége, amely jelentősen változó lehet az egyik helytől a másikra és a szárazföld felett mindig kisebb, mint a tengervíz felület felett;

d) az üzemi rádió rádiófrekvencia.

6.2.3.4 A vevőkészülék által vett zaj az alábbiaktól függ:

a) a vevőberendezés sávszélessége;

b) a légköri zaj szintje, ami az érintett földrajzi területnek megfelelően változó, a napszaktól és az évszaktól függő, és amely nagyon magas szintet érhet el a helyi zivatarok során;

c) az NDB és a vevőberendezés közötti terjedési út vezetőképesség, amely jelentősen változó lehet az egyik helytől a másikra és a szárazföld felett mindig kisebb, mint a tengervíz felület felett;

d) a légijárműben jelentkező elektromos zaj miatti zaj szintje, vagy az ipari zaj (elektromos motorok stb. által létrehozott zaj) akkor, amikor az NDB fedésrterülete ipari területekre is kiterjed.

6.2.3.4.1 Meg kell jegyezni azt, hogy a zaj hatása az ADF vevő és a hozzá kapcsolódó berendezések jellemzőitől, valamint a zaj természetétől is (pl. állandó zaj, pulzáló zaj) függ.

6.2.3.5 Egy további tényező, amely az NDB tényleges fedésterületét korlátozza, éjszaka jelentkezik, amikor a jel azon összetevői között lép fel kölcsönhatás, amelyek külön-külön a vízszinrtes síkban (földhullám terjedés) és az ionoszféráról való vissszaverődés (térhullám terjedés) útján terjednek. Amikor az ilyen összetevők között olyan kölcsönhatás van, hogy ezek az ADF vevőhöz fáziskülönbséggel érkeznek, akkor iránymérési hibákat hoznak létre (éjszakai hatás).

6.2.3.6 Így be kell látni azt, hogy egy NDB tényleges fedésterülete olyan sok olyan tényezőtől függ, ami változó, hogy lehetetlen az, hogy egy NDB tényleges fedésterülete egyszerű módon meghatározásra kerüljön. Minden NDB tényleges fedésterülete valójában a napszak és az évszak függvényében változó.

6.2.3.6.1 Ennélfogva bármilyen olyan kísérlet, hogy a tényleges fedésterület úgy kerüljön meghatározásra, hogy megkapható legyen a napszak bármely időpontjára, vagy egy egész éven át, vagy egy olyan fedésterületi számot eredményezne, ami túl kicsi lenne (mivel ez lenne az a fedésterület, ami a légköri zaj legrosszabb körülményei mellett elérhető), egy teljesen félrevezető képet adna az NDB hatékonyságáról, vagy olyan nagy teljesítményt és költséges antenna-rendszert (a szükséges teljesítménynek a legrosszabb feltételek melletti biztosítása) foglalna magába, hogy egy ilyen NDB telepítését eleve megakadályozná a telepítési és üzemeltetési költségek figyelembevétele. Semmilyen egyenlet nem adható meg annak meghatározására, hogy milyen névleges fedésterület lenne egyenértékű a megkívánt tényleges fedésterülettel, és az összefüggést körzetileg kell megállapítani.

6.2.3.7 Azok, akik az NDB fedésterület üzemeltetési szempontjaiban érintettek, a követelményeket rendszerint a megkívánt üzemi fedésterület kérdésében fogják mérlegelni, és a körzeti tervezésben általában arra lesz szükség, hogy az ilyen követelményeket a névleges fedésterület szempontjából értelmezzék, amiből az NDB szükséges alapvető jellemzői levezethetők lesznek, és ami meg fogja határozni azt a területet is, amelyet a káros interferencia ellen védeni kell. Semmilyen egyenlet nem adható meg annak meghatározására, hogy milyen névleges fedésterület lenne egyenértékű a megkívánt üzemeltetési fedésterülettel, és az összefüggést körzetileg kell megállapítani.

6.2.3.8 Néhány Államban rögzítették az NDB-k adatait és azok tényleges fedésterületét; és a hasonló információk összegyűjtése gyakorlatilag egy hasznos módszer lenne egy adott terület berendezései tényleges fedésterületének a névleges fedésterületben kifejezett értékeléséhez.

Ez a tájékoztatás hasznos lenne a jövő körzeti tervezéséhez is. A tényleges fedésterület megállapításához kapcsolódó számos tényező csökkentése céljából kívánatos lenne a rádióirányszög kijelző reagálásában kifejezett hasznos fedésterületi határvonal meghatározása követelményének megállapítása. Az előbbiekben említett adatok, az NDB fedésterületén belül mért tényleges térerősséggel együtt, lehetővé tennék a meglévő berendezések hatékonyságának a meghatározását is, és útmutatást adnának azokhoz a tökéletesítésekhez, amelyek szükségesek lehetnek a megkívánt tényleges fedésterület eléréséhez.

6.3 Az NDB-k fedésterülete

6.3.1 Bevezetés

6.3.1.1 Az alábbi tanulmány az ITU rendelkezésére álló legújabb hullámterjedési és zaj adatokon alapszik. Ezeket az adatokat ez a Melléklet az NDB-k tervezésére vonatkozó általános irányelvként foglalja magába. Különösen felhívjuk a figyelmüket a megadott elfogadott feltételekre.

6.3.1.2 Az anyag alkalmazásakor a feltételeknek a vizsgálat alatt álló egyedi körülményekre vonatkozó érvényességét gondosan meg kell vizsgálni, és különösképpen azt kell megjegyezni, hogy a feltételezett jel - zaj arányok további jelentékeny mértékű tanulmányozást igényelnek, mielőtt elfogadhatók lennének a hasznos vételt korlátozó arányok tipikus példájaként.

6.3.2 Feltételek

1. Üzemi frekvencia — 300 kHz.
Vonatkoztatva még azonban - ahol megfelelő - a 200 kHz-es és 400 kHz-es frekvenciákra.

2. a) Átlagos talaj vezetőképesség:
($\sigma = 10^{-13}$ elektromágneses egység)

b) Átlagos tengervíz vezetőképesség:
($\sigma = 4{,}10^{-11}$ elektromágneses egység)

3. A légköri zaj szintje (RMS = négyzetes középérték), ami valószínűleg előfordul: 1) nappal, 2) éjszaka, a szárazföld felett az említett földrajzi szélességi sávban. [A várható zaj értékei az ITU-R P.372-6 Ajánlásából kerültek levezetésre és a nap-éj egyenlőségi periódusok alatti nappali és éjszakai átlagos zaj értékeként kerültek elfogadásra, azaz azok az értékek, amelyek az év 20-25 százalékában várhatóan nagyobbak.]

4. Az NDB antennájába bevezetett teljesítmény:
a) 5 kW
b) 1 kW
c) 500 W
d) 100 W
e) 50 W
f) 10 W

5. Az antennák sugárzási hatásfokának átlagos értékei, azaz az, amely a következő:

$$\left[\frac{\text{Kisugárzott teljesítmény}}{\text{Az antennába bevezetett teljesítmény}}\right]$$

	Az antennába bevezetett teljesítmény	*Az antenna sugárzási hatásfoka*
a)	5 kW	20 % (-7 dB)
b)	5 kW	10 % (-10 dB)
c)	1 kW	8 % (-11 dB)
d)	500 W	5 % (-13 dB)
e)	100 W	3 % (-15 dB)
f)	50 W	2 % (-17 dB)
g)	10 W	1 % (-20 dB)
h)	10 W	0,3 % (-25 dB)

i) Az a) alatti értékek azért kerültek beépítésre, mert ezt a hatásfokot egy - a rendszerint alkalmazottnál - jobb kialakítású antenna-rendszer alkalmazásával el lehet érni.

ii) A h) alatti értékek azért kerültek beépítésre, mert számos kis- teljesítményű antennánál nagyon rossz hatásfokú antennát használnak.

6. Az ADF vevő admitancia sávja 6 kHz.

7. A jel - (medián) - zaj (négyzetes középérték) szükséges aránya:

a) 15 dB nappal;

b) 15 dB éjszaka.

6.3.3 A tanulmányok eredményei

A. — *A névleges fedésterület határvonalán szükséges minimális térerősség:*

	Földrajzi szélesség	*Nappal 15 dB-es jel-zaj viszonynál*	*Éjjel 15 dB-es jel-zaj viszonynál*
	5°N - 5°S	320 µV/m (+50 dB)	900 µV/m (+59 dB)
	5° - 15°N&S	85 µV/m (+39 dB)	700 µV/m (+57 dB)
	15° - 25°N&S	40 µV/m (+32 dB)	320 µV/m (+50 dB)
	25° - 35°N&S	18*µV/m (+25 dB)	120 µV/m (+42 dB)
	> 35°N&S	18*µV/m (+25 dB)	50 µV/m (+35 dB)

A számok mellett feltűntetett csillag azt jelzi, hogy magasabb térerősség értékre, lehetséges, hogy a feltűntetett érték kétszeresére, vagy háromszorosára lesz szükség (plusz 6-tól plusz 10 dB-ig) a nagy légijármű zajú és / vagy ipari zajú területeken.

B. — *Az NDB-k azon fedésterülete (olyan kör sugarában* - kilométerben megadva - amelynek a középpontjában van az NDB), amely az elfogadott feltételek mellett várható:

1) *Nappal, szárazföld felett,* és *15 dB-es jel-zaj arányra* a fedésterület határvonalánál:

Földrajzi szélesség	*Az antennába bevezetett teljesítmény*			
	(a) *5 kW*	(b) *5 kW*	(c) *1 kW*	(d) *500 W*
5°N - 5°S	320	300	170	120
5° - 15°N&S	510	470	320	250
15° - 25°N&S	> 600	600	450	350
25° - 35°N&S	> 600 *	> 600*	600 *	500 *
> 35°N&S	> 600 *	> 600 *	> 600 *	500 *

Földrajzi szélesség	*Az antennába bevezetett teljesítmény*			
	(e) *100 W*	(f) *50 W*	(g) *10 W*	(h) *10 W*
5°N - 5°S	50	30	10	< 10
5° - 15°N&S	150	90	40	10
15° - 25°N&S	220	160	70	45
25° - 35°N&S	330 *	250 *	130 *	80 *
> 35°N&S	330 *	250 *	130 *	100 *

2) *Éjszaka, szárazföld felett,* és *15 dB-es jel-zaj arányra* a fedésterület határvonalánál:

Földrajzi szélesség	*Az antennába bevezetett teljesítmény*			
	(a) *5 kW*	(b) *5 kW*	(c) *1 kW*	(d) *500 W*
5°N - 5°S	190	150	85	50
5° - 15°N&S	210	180	110	70
15° - 25°N&S	320	300	170	120
25° - 35°N&S	390	390	280	200
> 35°N&S	390	390	390	310

Földrajzi szélesség	*Az antennába bevezetett teljesítmény*			
	(e) *100 W*	(f) *50 W*	(g) *10 W*	(h) *10 W*
5°N - 5°S	20	< 10	< 10	< 10
5° - 15°N&S	25	15	< 10	< 10
15° - 25°N&S	50	30	10	< 10
25° - 35°N&S	100	70	25	15
> 35°N&S	180	120	50	30

6.3.3.1 Valamennyi fenti táblázathoz meg kell jegyezni azt, hogy:

a) a távolságok kilométerben vannak megadva, az ITU gyakorlatának megfelelően;

b) az utolsó oszlopban, a 10 W-os fejléc alatt feltűntetett számok azzal a feltétellel kerültek kiszámításra, hogy kisteljesítményű NDB-nél nagyon rossz hatásfokú antennát használnak (lásd az 5 h) alatti feltételt);

c) a számok mellett feltűntetett csillag azt jelzi, hogy a fedésterületet a légijármű és az ipari zajok korlátozhatják.

6.3.3.2 Azt is meg kell jegyezni, hogy:

a) ha a 200 kHz-es frekvenciát alkalmazzák a 300 kHz helyén, akkor az nem fogja észrevehetően befolyásolni egy kisteljesítményű, kis hatótávolságú NDB fedésterületét, azonban a nagyobb teljesítményű és nagyobb hatótávolságó rádióirányadók (például azok, amelyeknek a hatótávolsága 150 km, vagy több) fedésterülete a táblázatban feltűntetettekkel összehasonlítva körülbelül 20 százalékkal megnövekszik;

b) ha a 400 kHz-es frekvenciát alkalmazzák a 300 kHz helyén, akkor az nem fogja észrevehetően befolyásolni egy kisteljesítményű, kis hatótávolságú NDB fedésterületét, azonban a nagyobb teljesítményű és nagyobb hatótávolságó rádióirányadók (például azok, amelyeknek a hatótávolsága 150 km, vagy több) fedésterülete a táblázatban feltűntetettekkel összehasonlítva körülbelül 25 százalékkal lecsökken;

c) egy keskenyebb sávszélességű ADF vevőkészülék alkalmazása, a többi tulajdonságot változatlannak véve, szélesebb fedésterületet biztosít ugyanazon kisugárzott teljesítménynél, vagy azonos fedésterületet és javuló hatékonyságú jel-zaj viszonyt.

Például, ha a 6 kHz helyett 1 kHz-es admittancia sávot használnak, akkor a fedésterület akár 30 százalékig terjedő értékkel is megnövekedhet, ugyanazon kisugárzott teljesítmény mellett, vagy alternatívaként a tényleges jel-zaj viszony akár 8 dB-ig terjedően is megnövekedhet.

d) ha az NDB fedésterületének egy szektora tenger felett van, az adott szektoron belül nagyobb fedésterület várható a következők miatt:

1) a tengervíz felszín felett jobb a felületi hullámterjedés, mint a szárazföld felett;

2) a zajszint, amely a szárazföld felett magasabb, gyakran egészen meredeken csökken a szárazföldtől mért távolság növekedésével. Ennélfogva az várható, hogy a táblázatban feltűntetett értékek nappal körülbelül 30 százalékkal és éjszaka körülbelül 20 százalékkal megnövekedhetnek akkor, ha a terjedési út a tengerszint felszíne felett van;

e) ha azonban a rádióirányadó egy, a szárazföldtől távol lévő szigeten van telepítve (például a Közép-Csendes, vagy a Közép- Atlanti óceánban, de nem a Karib-tengeren), akkor a rádióirányadó fedésterülete valószínűleg jóval nagyobb lesz, különösen a trópusi szélességi fokokon, annál, mint ami a táblázatokban feltűntetésre került, és az ilyen esetekben azokkal megegyező számokat lehet elfogadni, mint amelyek a 35^{o} Észak és Dél szélességi körökön túlra kerültek megadásra, minden szélességnél a miatt az alacsonyabb szintű légtéri zaj miatt, ami a közép-óceáni területeken a szárazföldek felett, vagy azok közelében tapasztalatakhoz viszonyítva fennáll.

6.3.4 A rádióirányadó fedésterületének éjszakai csökkenése az "éjszakai hatás" miatt:

a) Azok a távolságok éjszaka, amelyeken a vett erőtér felületi hullámú és térhullámú összetevői valószínűleg egyenlőek, a következők:

Frekvencia	*Szárazföld felett*	*Tenger felett*
200 kHz	500 km	550 km
300 kHz	390 km	520 km
400 kHz	310 km	500 km

b) Azok a távolságok éjszaka, amelyeknél a vett erőtér felületi hulllám össszetevője valószínűleg 10 dB-el meghaladja a térhullámú összetevőt, a következők:

Frekvencia	*Szárazföld felett*	*Tenger felett*
200 kHz	300 km	320 km
300 kHz	230 km	300 km
400 kHz	200 km	280 km

c) Ez az, aminek következtében nem valószínű, hogy megbízható iránymérések kaphatók éjszaka a vett erőtér két összetevőjének egymásra hatása miatt, a 6.3.4 b) pontban feltűntetett értékeknél jóval nagyobbb távolságokban. Ezek a távolságok függetlenek az NDB teljesítményétől.

d) Ezenkívül meg kell jegyezni azt is, hogy amíg a jó vezetés szárazföldi útjai az éjszakai hatás miattt csak egy kicsit nagyobb távolságúak lesznek, jelentősebbek annál, mint ami a rossz vezetésű utakra megadásra került, az éjszakai hatás jóval rövidebb távolságokra válhat hangsúlyozottá. Ez bizonyos mértékben még a sugárzó rendszer jellemzőitől függő is lesz.

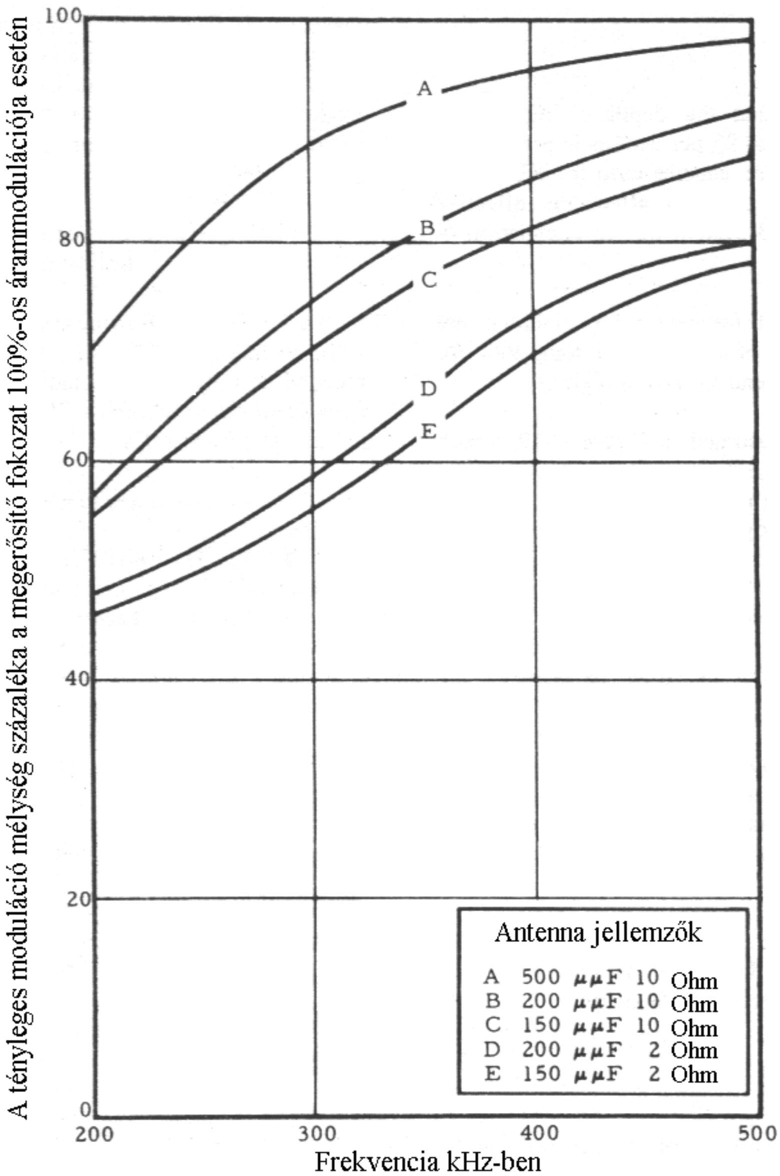
6.4 Az NDB-k üzemeltetését befolyásoló megfontolások

6.4.1 *Modulációs mélység*

6.4.1.1 Arra az előírásra vonatkozóan, hogy a modulációs mélységet annyira közel kell tartani a 95 százalékhoz, amennyire az gyakorlatilag megvalósítható, meg kell jegyezni azt, hogy az NDB-knél alkalmazott frekvenciáknál az általánosan használt kis antennák - az oldalsávok csillapítása miatt - hatással lehetnek az NDB rendszerek modulációs mélységére.

6.4.1.2 Ennél a frekvencia tartománynál az antennák szabályszerűen csak egy kis részét képezik a hullámhossz hosszának; így ennek megfelelően magas a reaktanciájuk, és magas Q értékre hajlamosak.

6.4.1.3 Ezt a hatást mutatja be a C-19. számú ábra, amely egy Állam mérései alapján került összeállításra. Ezeknél a méréseknél a modulációs frekvencia 1 020 Hz volt. Ha egy alacsonyabb modulációs frekvenciát használnának, akkor a hatás kisebb lenne.



Megjegyzés.-Ezeknél a méréseknél a moduláló frekvencia 1020 Hz volt.

C-19. ábra: Az antenna Q értékének a kisugárzott jel modulációs mélységére gyakorolt hatása

6.4.1.4 A csillapítás csökkentése céljából megpróbálták a Q értékét csökkenteni. Ezt kétféleképpen lehet végrehajtani, vagy a kapacitásának, vagy az ellenállásának a növelésével.

6.4.1.5 Egy kiegészítő ellenállásnak az antennába történő beiktatása csökkenti a teljesítményt, míg ellenben a kapacitás növelésének a hatása az, hogy csökkenti a rendszer feszültségét és ezáltal csökkenti a szigetelési problémákat.

6.4.1.6 Ezen okokból kívánatosnak tekinthető az, hogy növeljék az antenna kapacitását egy olyan antenna csúcs-terhelés alkalmazásával, mint például az úgynevezett ernyő csúcs-kapacitás.

6.4.2 *Földelési rendszerek*

6.4.2.1 A frekvencia tervezés azon az alapfeltételen nyugszik, hogy a térerősséget a pontos értékén fogják tartani. Ha a földelési ellenállás nagy (azaz nem kielégítő a földelési rendszer), akkor nemcsak a sugárzási hatékonyság lesz kicsi, hanem a kisugárzott teljesítmény lesz érzékeny az éghajlati viszonyok változásaira és az egyéb, földelési veszteséget befolyásoló tényezőre. Minden esetben a földelési rendszernek a lehető legjobbnak kell lenni az összes helyi körülményt beszámítva.

6.5 A NON / A2A üzemmódú NDB-k modulációs frekvenciája kiválasztását befolyásoló megfontolások

6.5.1 Annak a ténynek a felismerése, hogy a modern keskeny sávú automatikus rádióiránymérő (ADF) vevőknek megnövelt szelektivitási jellemzőjük van, szükségessé válik annak a tényezőnek a vizsgálata, hogy ezeknek a készülékeknek a hangfrekvenciás oldalsáv csillapítása a jel tényleges modulációs mélységének csökkentését is létrehozza, azaz az a távolság, amelynél a kielégítő azonosítás elérhető, ennek megfelelően lecsökken. Az ilyen körülmények mellett - úgy gondoljuk, hogy - a 400 Hz jobb azonosítási szolgáltatást fog biztosítani, mint az 1 020 Hz. Nyilvánvaló azonban az, hogy a nagy légköri zaj esetén az
1 020 Hz-es magasabb frekvencia jóval könnyebben olvasható jelet biztosíthat.

6.6 Útmutató anyag az NDB-k ellenőrzéséhez

6.6.1 Az alábbi pontokban a különféle ellenőrzések kívánt időszakosságának irányelvei kerülnek megadásra. Ezeknek az adatoknak csak általános útmutatás a céljuk, és elfogadott az, hogy számos helyi körülmény fogja befolyásolni az Államokat a saját ellenőrző programjuk meghatározásakor.

6.6.1.1 *Vivőfrekvencia*

6.6.1.1.1 A vivőfrekvencia pontosságát időszakosan ellenőrizni kell egy pontos szabványhoz viszonyítva annak biztosításához, hogy a 3. Fejezet 3.4.4.2 pontjában meghatározott tűréshatárokon belül marad. Egy szabvány mérőeszközt, például egy kristály-vezérelt - az üzemi frekvenciához viszonyított 0,001 százalékos pontosságú - frekvenciamérő felhasználása ajánlott erre a célra.

6.6.1.1.2 A vivőfrekvencia stabilitásának ellenőrzését a következők szerint kell elvégezni:

a) legalább félévenként a kristály-vezérelt adóknál;

b) legalább havonta egyszer a nem-kristály-vezérelt adóknál.

6.6.1.1.3 Ha gyakorlatilag megvalósítható, akkor az ellenőrzéseket rövidebb időszakonként kell elvégezni.

6.6.1.2 *A moduláló hang frekvenciája*

6.6.1.2.1 Az azonosító frekvenciára vonatkozó követelmények a 3. Fejezet 3.4.5.4 pontjában kerültek előírásra. Egy olyan hangfrekvenciás jelgenerátor alkalmazása javasolt kalibrációs szabványként, amelynek a pontossága a meghatározott frekvenciához viszonyítva 0,5 százalékos, vagy annál jobb pontosságú.

6.6.1.2.2 Ezt az ellenőrzést legalább havonta egyszer el kell végezni.

6.6.1.3 *A felületi hullám térerőssége*

6.6.1.3.1 Az az ajánlott, hogy távol-téri térerősség méréseket végezzenek egy olyan térerősség jelző berendezéssel, amely képes annak ellenőrzésére, hogy az NDB kisugárzott teljesítménye megfelel a 3. Fejezet 3.4.3 pontjában leírtaknak.

6.6.1.3.2 Ezt az ellenőrzést legalább havonta egyszer el kell végezni.

6.6.1.4 *Modulációs mélység*

6.6.1.4.1 A 3. Fejezet 3.4.6.2 pontja előírja azt, hogy a vivőfrekvencia modulációs mélységét annyira közel kell tartani a 95 százalékhoz, amennyire az csak lehetséges. Egy, az NDB adó frekvenciáján működni képes oszcilloszkóp ajánlható erre az ellenőrzési célra.

6.6.1.4.2 Ezt az ellenőrzést az oszcilloszkóp felhasználásával legalább három hónaponként el kell végezni. Ezenkívül a modulációs mélység hozzávetőleges ellenőrzését egy kalibrált diódás-voltmérő felhasználásával gyakrabban is el lehet végezni, de az nem kielégítő az oszcilloszkópot alkalmazó ellenőrzés helyettesítésére.

6.6.1.4.3 A nem-kívánt hangfrekvenciás modulációt legalább három hónaponként meg kell mérni annak biztosításához, hogy az nem haladja meg a 3. Fejezet 3.4.5.6 pontjában megadott határértékeket. Egy oszcilloszkóp ajánlott ehhez az ellenőrzéshez.

6.6.1.5 *A vivőhullám teljesítmény csökkenése a modulációval*

6.6.1.5.1 Amikor a moduláció rákerül a vivőhullámra, akkor a vivőhullám teljesítménye nem csökkenhet a 3. Fejezet 3.4.6.4 pontjában meghatározott értéknél többel. Ennek biztosításához az ajánlott módszer egy olyan hitelesített távközlési vevőnek - amelynek egy folyamatos hullámú középfrekvenciás kristályszűrője van - egy megfelelő távoli helyen való felhasználása az adó térerejének jelzésére, amelynek a szelektivitása kielégítő ahhoz, hogy a hangfrekvenciás oldalsávokat kiszűrje.

6.6.1.5.2 Egy alternatív, de valószínűleg kevésbé pontos módszer a vivőhullám teljesítmény-csökkenésének meghatározására az antennába táplált áram összehasonlítása az adó modulált és modulálatlan állapotában.

6.6.1.5.3 Ezt az ellenőrzést legalább havonta egyszer el kell végezni.

7. A DME berendezésekre vonatkozó anyag

7.1 A DME / N és DME / P berendezésekre vonatkozó útmutató anyag

7.1.1 A rendszer hatékonysága

7.1.1.1 A rendszer hatékonysága a fedélzet - föld kapcsolatú jelromlás (garble), a földi válaszadó berendezés holtideje, a föld - fedélzet kapcsolatú jelromlás (garble) és a kérdező adó-vevő feldolgozó egység hatékonysága. Mivel ezeknek a hatékonysági összetevőknek mindegyike statisztikailag független, ezért egyenként lehet őket kiszámítani, és azután ezeket összekapcsolni ahhoz, hogy a rendszer hatékonyságát megadja. Egy egyedüli összetevő hatását úgy kell meghatározni, mint a kérdező adó-vevőnek a saját kérdéseire adott válaszjelek érvényes válaszainak százalékos arányát, feltételezve azt, hogy az összes egyéb összetevő "nincs jelen". A rendszer hatékonysága azután az egyedi összetevők szorzata.

7.1.1.2 A rendszer hatékonyságának számításánál a hiányzó válaszokat, valamint a vett válaszok által létrehozott távolságmérések pontosságát kell figyelembe venni. A hiányzó válaszok a jelromlás miatti jel interferenciából, vagy a válaszadó holtidő periódusa alatt vett kérdésekből jöhetnek létre. Azokat a válaszokat, amelyek olyan jelentős hibákat tartalmaznak, amelyek elegendően nagyok ahhoz, hogy a kérdező adó-vevő jelfeldolgozása visszautasítsa azokat, ugyancsak hiányzó válaszként kell kezelni a hatékonysági összetevő kiszámításánál.

7.1.1.3 A jelromlás miatti interferencia arány a csatorna kiosztási terv, a forgalmi terhelés és a földi válaszadó, valamint a kérdező adó-vevő sávszélesség függvénye. Mivel a végső megközelítési (FA) módnál szélesebb a vevő sávszélessége, mint a kezdeti megközelítési (IA) módnál, ezért az jóval érzékenyebb az interferenciára. Ezek a tényezők beépítésre kerültek a DME / P rendszer meghatározásába, és általában nem igényelnek az üzemeltetési hatóságoktól különleges számításba vételt.

7.1.2 Fedélzet - föld kapcsolatú jelromlás

7.1.2.1 A fedélzet - föld kapcsolatú jelromlás akkor fordul elő, amikor a földi válaszadónál az érvényes kérdezéseket a többi repülőgéptől eredő egyidejű kérdezések zavarják, és ennek eredménye a jel elvesztése, vagy a beérkezési idő mérési hibák létrehozása. Ez a nem-kívánt levegő - föld terhelés a kiszolgáló válaszadó környezetében lévő kérdező légijárművek számának függvénye és még a kérdező frekvenciák megfelelő kiosztásától, valamint a válaszadónál vett jel amplitudójától függ.

Megjegyzés. - A válaszadó - válaszadó közötti jelromlást a csatornákat elosztó hatóságok ellenőrzik.

7.1.3 Föld - fedélzet kapcsolatú jelromlás

7.1.3.1 A föld - fedélzet kapcsolatú jelromlás akkor fordul elő, amikor a kérdező adó-vevőnél az érvényes válaszok más válaszadók jeleivel interferálnak, és ez jel elvesztés, vagy a beérkezési idő impulzus mérés hibáit hozza létre. A jeltorzulási interferencia felléphet bármilyen olyan válaszadótól, amelynek a frekvenciája a kérdező adó-vevő sávszélességén belül van, beleértve azokat is, amelyek ugyanazon a frekvencián, de más impulzus kódolással működnek.
Ez a nem-kívánt föld - levegő terhelés a kérdező adó-vevő környezetében lévő válaszadók számának a függvénye és még a válasz-frekvenciák megfelelő kiosztásától, valamint a kérdező adó-vevőnél vett jel amplitúdójától függ.

7.1.4 A kérdező jelfeldolgozó egység hatékonysága

7.1.4.1 A kérdező jelfeldolgozó egység hatékonyságát a kérdező adó-vevő által feldolgozott válaszok számának a jelromlás nélküli és a válaszadó holtidő hatása nélküli kérdezések számához viszonyított aránya adja meg. Ez a hatékonyság a válaszjel impulzusok küszöbszintjétől és a vevő zajszintjétől függ.

7.1.5 A kiszolgált légijárművek és a jelátviteli sebesség közötti összefüggés

7.1.5.1 A maximális válaszadó jelátviteli sebesség előírás meghatározza a maximális átlagos adó jeltovábbítási teljesítmény szintet. A 3. Fejezet 3.5.4.1.5.5 pont azt ajánlja, hogy a válaszadó jelátviteli sebesség képessége 2 700 másodpercenkénti impulzus-pár legyen akkor, amikor 100 légijárművet szolgál ki. Ez a 100 légijárműtől eredő jellemző válaszadó terhelést jelképezi. A tényleges jelátviteli sebesség képesség meghatározásával azt kell abba beleérteni, hogy egy adott berendezésnél a forgalmi csúcs körülmények esetén mi az a maximális kérdezési szám, ami várható. A válaszadó lekérdezési terhelésének kiszámításánál a következőket kell számításba venni:

a) forgalmi csúcsterhelést létrehozó légijárművek számát;

b) az egyes légijárműveken alkalmazott kérdező berendezések számát;

c) a használatos kérdező berendezések üzemeltetési módjának megoszlását (például kereső, kezdeti megközelítési, végső megközelítési és földi ellenőrzés);

d) a megfelelő impulzus ismétlődési frekvenciát, ahogy az a 3. Fejezet 3.5.3.4 pontjában megadásra került.

7.1.5.2 Megadva a válaszadóra jutó, a forgalmi csúcsból eredő lekérdezési terhelést, valamint a válaszadónak az ezen terhelés melletti válaszolási hatékonyságát, ki lehet számítani a létrejövő válaszolási sebességet, és ezáltal meg lehet határozni a szükséges adási teljesítőképességet. Ez a válaszadási sebesség az a szint, ami ha túllépésre kerül, a vevő érzékenység csökkenését eredményezi (ahogy az a 3. Fejezet 3.5.4.2.4 pontjában meghatározásra került), azért, hogy a válaszadási sebességet a berendezés a maximális szinten vagy az alatt tartsa.

7.1.6 Az ILS-hez, vagy az MLS-hez kapcsolt DME telepítése

7.1.6.1 A DME-nek - ahol csak lehetséges - a légijármű vezetője részére a kijelzett nulla távolságot a földetérési pontnál kell biztosítania, azért, hogy a jelenlegi üzemeltetési követelményeket kielégítse.

7.1.6.2 A DME válaszadó optimális telepítési helye több technikai és üzemeltetési tényezőtől függ. A DME / N berendezést együtt lehet telepíteni az ILS-el, vagy az MLS-el ott, ahol az üzemeltetési követelmények lehetővé teszik. A DME / P berendezés, amely nagyobb pontosságot és fedésterületet biztosít a futópálya teljes körzetében, az olyan jóval rugalmasabb és fejlettebb technikájú üzemeltetésekhez szükséges, mint ami az MLS-el érhető el.

7.1.6.3 A DME / N esetében a nulla távolság kijelzésére vonatkozó előírást úgy lehet elérni, hogy a válaszadót olyan közel telepítik ahhoz a ponthoz, ahova a nulla távolság kijelzés szükséges, amennyire az csak lehetséges. Alternatívaként, a válaszadó időkésleltetését lehet úgy beállítani, hogy lehetővé tegye a légijármű kérdező részére a nulla távolságnak a DME antennától egy meghatározott távolságra való kijelzését. Amikor a nulla távolságnak nem a DME antenna a referencia pontja, akkor gondoskodni kell arról, hogy ez a tájékoztatás közzétételre kerüljön.

7.1.6.4 A DME / P esetében, abból a célból, hogy a berendezés a pontossági és fedésterületi követelményeknek megfeleljen, különösen a futópálya körzeti követelményeknek, az az ajánlott, hogy a DME / P berendezés olyan közel kerüljön az MLS oldalszög adó berendezéshez, amennyire az csak lehetséges, az akadálymentességi követelményeknek megfelelően. Egy teljes MLS technikai képességgel felszerelt légijármű részére a megkívánt nulla távolság kijelzést az MLS alap-adatok felhasználásával lehet biztosítani. Jegyezzék meg azt, hogy a DME / P válaszadó időkésleltetését nem szabad ebből a célból szabályozni.

7.1.6.5 Kívánatos, hogy az összes felhasználó kapjon földetérésnél kijelzett nulla távolságot, tekintet nélkül a légijárművön felszerelt berendezésre. Ez szükségessé teszi a DME / P-nek a földetérési pontnál a futópályára merőlegesen történő elhelyezését. Ebben az esetben a DME / P-re vonatkozó pontossági követelmények nem felelnek meg a futópályán. Meg kell jegyezzük, hogy az MLS 3. Alap Adatszó csak bizonyos határok között engedélyezi a DME / P koordinátáinak kódolását.

7.1.6.6 Amikor egy MLS / DME / P és egy ILS / DME / N szolgálja ki ugyanazt a futópályát, akkor egy, a minimális MLS technikai képességgel felszerelt légijármű a nulla távolság kijelzést a megközelítési oldalszög adó berendezés telepítési helyére kaphatja meg akkor, amikor az MLS szerint üzemel, és nulla távolság kijelzést kaphat a földetérési pontra akkor, amikor az ILS szerint üzemel. Mivel ezt különösen az ATC nézőpontjából üzemeltetésileg elfogadhatatlannak tartják, és ha az ILS / MLS / DME frekvencia megháromszorozódás meghiúsítja a DME / N frekvencia kijelölését, és ez nem lehetséges, akkor a DME / P berendezés telepítését el kell halasztani addig, amíg a DME / N visszavonásra kerül.

7.1.6.7 A DME / N kérdező által biztosított nulla távolság kijelzés névleges helyét közzé kell tenni.

7.1.6.8 A DME telepítési helyének vizsgálatánál az olyan technikai tényezőket is számításba kell venni, mint a futópálya hossza, profilja, a helyi terepviszonyok és a válaszadó antenna magassága, ahhoz, hogy a kielégítő jelszintet a futópálya küszöbének körzetében és a futópálya teljes hosszában biztosítsák. Figyelemmel kell lenni arra is, hogy ahol távolság tájékoztatás szükséges, a futópálya körzetében, ott a kiválasztott telepítési hely ne okozza azt, hogy a kérdező elveszítse a követést a sebesség változása miatt.

7.1.7 Földrajzi elkülönítési követelmények

7.1.7.1 Abból a célból, hogy a jelenlegi antenna tervezési, berendezés jellemzők és szolgálati hatótávolság figyelembevételét lehetővé tegyék, a DME csatornákon üzemelő különféle berendezések interferencia-mentes üzemeltetésének biztosításához a szükséges jelviszonyokat az alábbi 7.1.8, 7.1.9 és 7.1.10 pontban adjuk meg. Ezeket a jelviszonyokat figyelembevéve a berendezések földrajzi elkülönítését könnyen ki lehet fejezni a terjedési úton bekövetkező veszteségek számításba vételével.

7.1.8 *A megkívánt és nem-kívánt (D/U) jelviszonyok a fedélzeti vevőnél*

7.1.8.1 A C-4. táblázat adja meg azokat a szükséges megkívánt / nem-kívánt jelviszonyokat, amelyek a megkívánt válaszadó jelek védelméhez a légijármű fedélzeti vevőjének szükségesek, azokkal a különféle azonos csatornájú / szomszédos csatornájú, azonos kódú / eltérő kódú, nem-kívánt válaszadó válaszjelek kombinációjával szemben, amelyek előfordulhatnak. A kezdeti kijelölésnél a megkívánt / nem-kívánt jelviszonyokra a légijármű fedélzeti berendezés 6-mikromásodperces dekóder lezárás alkalmazásával kell védeni. A frekvencia kijelölés végrehajtásánál minden egyes berendezést úgy kell kezelni, mint egy olyan megkívánt forrást, ami a másiknál nem-kívánt forrásként jelentkezik. Ha mindkettő kielégíti az egyedi megkívánt / nem-kívánt jelviszony követelményét, akkor a csatorna kiosztás végrehajtható.

7.1.8.2 Ennek megfelelően, a DME csatorna kijelölés a következőktől függ:

a) *Azonos csatornák kijelölése.* Ez a helyzet akkor áll fenn, amikor mind a megkívánt, mind a nem-kívánt jelek egy csatornán üzemelnek (W, X, Y vagy Z), ami azonos frekvenciájú és azonos kódú. A megkívánt / nem-kívánt jelviszonynak legalább 8 dB-nek kell lenni a teljes szolgálati hatótávolságon belül.

b) *Azonos frekvencia eltérő kód kijelölése.* Ez a helyzet akkor áll fenn, amikor az egyik berendezés egy X csatornán üzemel és a másik egy W csatornán. Hasonló Y csatorna és Z csatorna kombináció is alkalmazható.

c) *Első szomszédos frekvencia, ugyanazon kód kijelölése.* Ez a helyzet akkor áll fenn, amikor mind a megkívánt, mind a nem-kívánt berendezések W, X, Y vagy Z típusúak.

d) *Első szomszédos frekvencia, eltérő kód kijelölése.* Ez a helyzet akkor áll fenn, amikor az egyik berendezés egy X csatornán működik, és a másik egy W csatornán, de 1 MHz-es eltolással a válaszadó válasz-frekvenciái között. Egy hasonló Y csatorna és Z csatorna kombináció is alkalmazható.

e) *Második szomszédos frekvencia azonos, vagy eltérő kód kijelölése.* A második szomszédos frekvencia kombinációkat általában nem szükséges védeni. Azonban különös figyelmet kell fordítani a C-4. táblázat 4. Megjegyzésére, különösen akkor, ha a nem-kívánt berendezés egy DME / P válaszadó.

C-4. táblázat: A megkívánt / nem-kívánt jel védelmi aránya (dB)

A kijelölés típusa		A	B
Azonos frekvencia			
	Azonos impulzus kód	8	8
	Eltérő impulzus kód	8	-42
Első szomszédos frekvencia			
	Azonos impulzus kód	$-(P_u - 1)$	-42
	Eltérő impulzus kód	$-(P_u + 7)$	-75
Második szomszédos frekvencia			
	Azonos impulzus kód	$-(P_u + 19)$	-75
	Eltérő impulzus kód	$-(P_u + 27)$	-75

1. Megjegyzés. - Az A-oszlopban lévő megkívánt / nem-kívánt jel viszonyok azokat a DME / N kérdező berendezéseket védik, amelyek az X, vagy Y csatornákon működnek. Az A-oszlopnál a dekóder lezárásra 6 mikromásodperc került alkalmazásra.

2. Megjegyzés. - A B-oszlopban lévő megkívánt / nem-kívánt jelviszonyok azokat a DME / N vagy DME / P kérdező berendezéseket védik, amelyeknél a 3. Fejezet 3.5.5.3.4.2 és 3.5.5.3.4.3 pontjában leírtakkal megegyező megkülönböztetéseket alkalmaznak, és a 3. Fejezet 3.5.5.3.5 pontjában megadottaknak megfelelő dekóder lezárást biztosítják.

3. Megjegyzés. - A P_u a nem-kívánt jel kisugárzott csúcsteljesítménye dBW-ban.

4. Megjegyzés. - A frekvencia védelmi követelmény a megkívánt és nem-kívánt jelet adó berendezés antenna karakterisztikájától és a nem-kívánt jelet adó berendezés kisugárzott teljesítményétől függ.

5. Megjegyzés. - A szomszédos csatorna védelmének megállapításánál az A-oszlopban lévő megkívánt / nem-kívánt jelviszony nagysága nem haladhatja meg a B-oszlopban lévő értékek nagyságát.

7.1.9 *Különleges figyelembe veendő* tényezők *a DME Y és Z csatornák kijelöléséhez*

7.1.9.1 Azon Y, vagy Z csatornák kijelölésénél, amelyeknek a válasz frekvenciája 63 MHz 'távolságra' van egy másik csatorna válasz frekvenciájától (akár egy W, X, Y vagy Z csatornától), vagy viszont, a berendezések között minimálisan 28 km (15 tengeri mérföld) távolsági elkülönítés szükséges.

7.1.10 *Különleges figyelembe veendő tényezők a DME W, vagy Z csatornák kijelölésében*

Azon W, vagy Z csatornák kijelölésénél, amelyeknek a válasz frekvenciája 63 MHz 'távolságra' van egy Y csatorna válasz frekvenciájától, vagy viszont, a berendezések között minimálisan olyan elkülönítési távolság szükséges, ami legalább egyenlő az Y csatornájú berendezés szolgálati hatótávolságával plusz 28 km-el (15 tengeri mérföld).

7.1.11 *Különleges figyelembe veendő tényezők az impulzus spektrum mérések elvégzéséhez*

A 3.5.4.1.3 e) pontban meghatározott 0,5 MHz-es mérési frekvenciasávban lévő kisugárzott teljesítmény úgy számítható ki, hogy összegezzük a frekvencia-tartományban lévő teljesítmény-sűrűség spektrumot, vagy ezzel egyenértékűen úgy, hogy összegezzük az idő- tartományban az időegységenkénti pillanatnyi teljesítményt a megfelelő analóg, vagy digitális jelfeldolgozó technikát alkalmazva. Ha az összegzés a frekvencia-tartományban kerül végrehajtásra, akkor a spektrum elemző felbontási sávszélességének arányosnak kell lenni a DME impulzus idő-tartományának az 5 százalékával. Ha az összegzés az idő-tartományban kerül végrehajtásra, a 0,5 MHz-es öt-pólusú (vagy több) szűrő kimeneten, akkor az idő mintavételi gyakoriságnak arányosnak kell lenni az impulzus spektrum szélességgel.

7.1.12 *Különleges figyelembe veendő tényezők az ILS-hez kapcsoltan telepített DME / P berendezéseknél*

7.1.12.1 Azoknál a futópályáknál, ahol az a cél, hogy egy ILS-hez kapcsolt DME-t telepítsenek, és ahol kezdeti MLS / RNAV üzemeltetéseket terveznek, a DME / P berendezés telepítését kell előnyben részesíteni.

7.1.12.2 Amikor az a cél, hogy a DME / P távolságmérő információját a közelkörzet teljes területén fel akarják használni, ott a pontos jelszünetű kérdező impulzus-párokat és a névleges frekvenciát a válaszadónak kell indítani, akkor, ha a válaszadó antennánál a csúcs teljesítmény-sűrűség legalább mínusz 93 dBW/m^2. Ez az érzékenységi szint a 3. Fejezet 3.5.4.2.3.1 pontjában lévő értékeken alapszik, és a DME / P kezdeti megközelítési módjára van alkalmazva, ahol ennél a szintnél a DME / P kezdeti megközelítési mód célja az, hogy megfeleljen a DME / N válaszadási teljesítményének és legalább a DME / N pontosságának.

7.2 A csak a DME / N berendezésre vonatkozó útmutató anyag

7.2.1 A DME / N berendezések kisugárzott teljesítménye (ERP)

7.2.1.1 A 3. Fejezet 3.5.4.1.5.1 pontjában előírt teljesítmény-sűrűség a következő alapfeltételeken alapszik:

Légijármű fedélzeti vevő érzékenység	-112 dBW
Légijármű fedélzeti tápvonal veszteség	+3 dB
Légijármű fedélzeti sugárzási diagram veszteség egy izotróp antennához viszonyítva	+4 dB
Az antennánál szükséges teljesítmény	-105 dBW

Az antennánál a mínusz 105 dBW mínusz 83 dBW/m^2-nek felel meg a közepes átviteli frekvenciánál.

Megjegyzés. - Az egy izotróp antennára vonatkozó teljesítmény-sűrűséget a következő módon lehet kiszámítani:

$$P_d = P_a - 10 \log \frac{\lambda^2}{4\pi}$$

ahol: P_d *= a teljesítmény-sűrűség dBW/m*^{2}*-ben;*

P_a *= a teljesítmény a vételi pontnál dBW-ban;*

λ *= a hullámhossz méterben.*

7.2.1.2 A mínusz 83 dBW/m^2 teljesítmény-sűrűség eléréséhez szükséges kisugárzott teljesítmény névleges értékei a C-20. számú ábrán kerültek megadásra. A nehéz terepviszonyok és telepítési körülmények melletti fedésterületre szükséges lehet az, hogy a kisugárzott teljesítményt megfelelően növeljék. Ellenkező esetben kedvező telepítési körülmények esetén a megállapított teljesítmény-sűrűséget kisebb kisugárzott teljesítménnyel is el lehet érni.

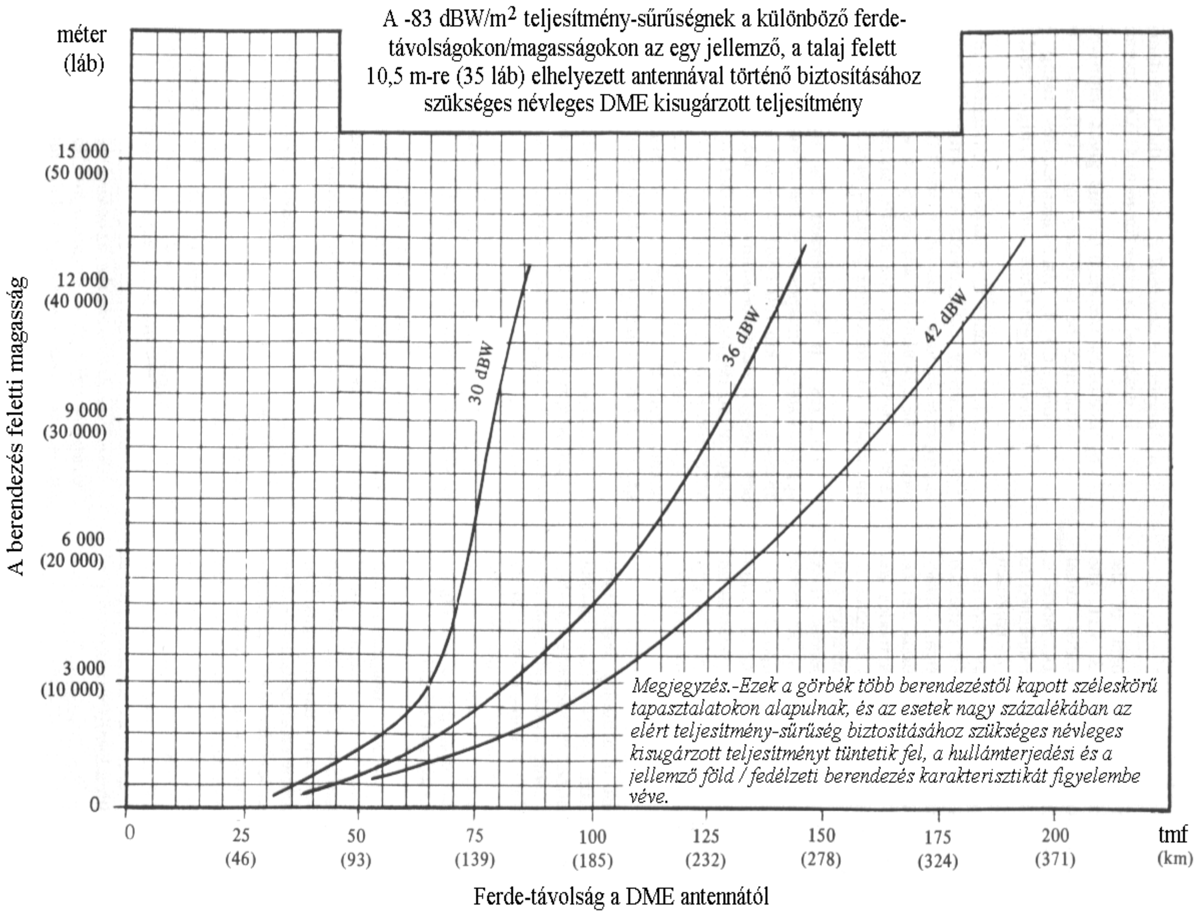
7.2.1.3 A C-20. sz. ábra alkalmazását a következő példák mutatják be. Azért, hogy a szükséges névleges teljesítmény-sűrűség elérésre kerüljön a 342 km-es ferdetávolságnál (185 tengeri mérföld) a 12 000 m (40 000 láb) magasságon és a 263 km-es (142 tengeri mérföld) ferdetávolságnál a 12 000 m (40 000 láb) magasságon, illetve a 135 km-es (73 tengeri mérföld) ferdetávolságnál a 6 000 m-es (20

000 láb) magasságon külön-külön plusz 42 dBW, plusz 36 dBW, illetve plusz 30 dBW kisugárzott teljesítményre lesz szükség.

7.3 A csak a DME / P berendezésre vonatkozó útmutató anyag

7.3.1 A DME / P berendezés rendszer leírása

7.3.1.1 A DME / P berendezés a 3. Fejezet 3.11 pontjában leírt mikrohullámú leszállító rendszer szerves része. A DME / P jel formátum két üzemelési módot határoz meg, a kezdeti megközelítési (IA) és a végső megközelítési (FA) módot. A kezdeti megközelítési mód kompatibilis és együtt működtethető a DME / N-el és arra a célra tervezték, hogy javított pontosságot biztosítson a megközelítés és a leszállás kezdeti szakaszaiban. A végső megközelítési mód lényegesen nagyobb pontosságot biztosít a végső megközelítési területen. Mindkét üzemmód egy egyedüli DME / P földi berendezésben van egyesítve, és a rendszer jellemzője olyan, hogy a DME / N és a DME / P funkcióit össze lehet kapcsolni egy egyedüli kérdezőben. A kezdeti megközelítési és a végső megközelítési módok a 3. Fejezet 3.5.4.4 pontjában meghatározott impulzus kódokkal kerülnek azonosításra. Az MLS megközelítési szektorában a DME / P berendezés fedésterületének legalább 41 km-nek (22 tengeri mérföld) kell lenni a földi válaszadótól mérve. Az a cél, hogy a kérdező ne működjön a válaszadó telepítési helyétől mért 13 km-nél (7 tengeri mérföld) nagyobb távolságban végső megközelítési üzemmódban, jóllehet, a kezdeti megközelítési módról való átállás a válaszadótól mért 15 km-nél (8 tengeri mérföld) kezdődhet meg. Ezek a számok azon az előfeltételen alapulóan kerültek kiválasztásra, hogy a válaszadó a futópálya megállási végén túl, a futópálya küszöbétől körülbelül 3 600 m (2 tengeri mérföld) távolságra van telepítve.



C-20. ábra

7.3.1.2 A megközelítési és leszállási műveletek végső szakaszaiban előforduló pontosság csökkenés nagyobb lehetséges okozója a többutas (jel-visszaverődéses) interferencia. A DME / P berendezés végső megközelítési módja minimálisra csökkenti ezeket a hatásokat úgy, hogy olyan szélessávú impulzus jelfeldolgozást alkalmaz, amelynél gyors az impulzus-felfutás felfutási ideje és a beérkezési időt a vett impulzusok egy olyan alacsony pontján méri, ahol még nincs a többutas terjedés miatt jelentős jelromlás. Ezzel szemben egy alacsonyabb impulzus felfutási időt és egy magasabb, az 50 százalékos jelszintnél bekövetkező küszöbértéket alkalmaznak a DME / N berendezésekben.

7.3.1.3 Mivel a végső megközelítési mód a 13 km-nél (7 tengeri mérföld) kisebb távolságban kerül alkalmazásra, az adó megfelelő jelszintet tud biztosítani ahhoz, hogy a szükséges pontosságot anélkül kielégítse, hogy a gyors impulzus felfutási idő rontaná a válaszadó impulzus spektrum követelményeit. Az 50 százalékos küszöbérték és a keskenyebb vevő sávszélesség alkalmazása a kezdeti megközelítési módnál lehetővé tesz egy kielégítő, de kisebb követelményű teljesítményt a fedésterületi határvonalakig. A válaszadó határozza meg a lekérdezési módot egy lekérdező kódnak az olyan felhasználásával, ami időzíti a válasz késését a megfelelő mérési referenciától. A kezdeti megközelítési mód együttműködőképes a DME / N berendezéssel és lehetővé teszi azt, hogy egy DME / N kérdező kerüljön a DME / P válaszadóval együtt felhasználásra úgy, hogy legalább elérje a DME / N válaszadó pontosságát. Hasonlóképpen a DME / P kérdezőt fel lehet használni a DME / N válaszadóval együtt.

7.3.2 *A DME / P berendezés rendszer pontossági követelményei*

7.3.2.1 *A DME / P berendezés pontossági követelményei*

7.3.2.1.1 Amikor a DME / P berendezés pontossági követelményeit mérlegelik, akkor azok az üzemeltetések, amelyeket a végső megközelítési mód szolgálati hatótávolságában végre lehet hajtani, két csoport valamelyikébe sorolhatók. Ez vezetett arra, hogy két pontossági szabvány került meghatározásra a végső megközelítési módra:

a) *1. pontossági szabvány:* ez a kisebb követelményű és a legtöbb hagyományos fel- és leszállású (CTOL) üzemeltetés kiszolgálására tervezett pontosság;

b) *2. pontossági szabvány:* ez megnövelt pontosságot ad, és ez lehet szükséges a függőleges fel- és leszállású (VTOL), valamint a rövid fel- és leszállású (STOL) üzemeltetésekhez, valamint az MLS kilebegtetési magassági vezérlést felhasználó hagyományos fel- és leszállású üzemeltetések kilebegtetési manővereihez és a hagyományos fel- és leszállású üzemeltetések nagysebességű futópálya elhagyási manővereihez.

7.3.2.1.2 A C-5. táblázat mutatja be a DME és a jellemző pontossági követelmények alkalmazását. Ez segítséget fog nyújtani a megfelelő pontossági szabvány kiválasztásához úgy, hogy azok megfeleljenek az üzemeltetési követelményeknek. A számítások a DME antenna és a futópálya küszöb közötti 1768 méteres (5 800 láb) távolságon alapulnak. A következő pontok a C-5. táblázatra vonatkoznak.

7.3.2.1.3 Az a cél, hogy a DME / P pontossága körülbelül feleljen meg az oldalszög funkció útvonal-követési hiba (PFE) értékének az MLS vonatkozási ponttól mért 37 km-es (20 tengeri mérföld) távolságnál, mind a meghosszabbított középvonal mentén, mind a 40 fokos oldalszög értékeknél. Ugyanígy a DME / N berendezés hibája az MLS fedésterületének határvonalainál egyezzen meg a 3. Fejezet 3.5.3.1.3.3 pontja rendszer pontossági 0,37 km-es (0,2 tengeri mérföld) értékével. A kormányzási elmozdulási zaj (CMN) a plusz, vagy mínusz 0,1 fok kormányzási elmozdulási érték lineáris megfelelője legyen, ahogy az az oldalszög útirány-vezetési szög funkcióra meghatározásra került.

7.3.2.1.4 Az útvonal-követési hiba (PFE) az oldalszög szöghibának felel meg, a kormányzási elmozdulás zaj (CMN) körülbelül az oldalszög útirány-vezetési szög rendszerre meghatározott 0,1 fok kormányzási elmozdulási zaj (CMN) lineáris megfelelője.

7.3.2.1.5 A plusz, vagy mínusz 30 méteres útvonal-követési hiba (PFE) plusz, vagy mínusz 1,5 méteres függőleges hibának felel meg egy 3 fokos magassági szögnél.

7.3.2.1.6 A kilebegtetés megkezdése az MLS megközelítési vonatkozási pont közelében történik, az MLS magassági szöge és a DME / P biztosítja a függőleges útirány-vezetést az automatikus leszálláshoz akkor, amikor a futópálya küszöbe alatti terepfelszín egyenetlen.

7.3.2.1.7 Az érzékenység módosulása, vagy a robotpilóta erősítés szabályozására vonatkozó körülmények nem függnek közvetlenül a pontosságtól.

C-5. Táblázat

Funkció	Jellemző távolság a küszöbtől	Útvonal-követési hiba (95 %-os valószínűség)	Kormányzási elmozdulási zaj
Megközelítés (7.3.2.1.3)			
— a futópálya meghosszabbított középvonalán	37 km (20 tengeri mérföld)	±250 m (± 820 láb)	±68 m (±223 láb)
— a 40°-os oldalszögnél	37 km (20 tengeri mérföld)	±375 m (±1 230 láb)	±68 m (±223 láb)
Megközelítés (7.3.2.1.4)			
— a futópálya meghosszabbított középvonalán	9 km (5 tengeri mérföld)	±85 m (±279 láb)	±34 m (±111 láb)
— a 40°-os oldalszögnél	9 km (5 tengeri mérföld)	±127 m (±417 láb)	±34 m (±111 láb)
Helyjeladó helyettesítés			
— külső helyjeladó	9 km (5 tengeri mérföld)	±800 m (±2 625 láb)	nem alkalmazható
— középső helyjeladó	1 060 m (0,57 tengeri mérföld)	±400 m (±1 312 láb)	nem alkalmazható
A 30 méteres elhatározási magasság meghatározása (100 láb) (7.3.2.1.5)			
— 3°-os siklópálya (hagyományos fel- és leszállás)	556 m (0,3 tengeri mérföld)	±30 m (±100 láb)	nem alkalmazható
— 6°-os siklópálya (rövid fel- és leszállás)	556 m (0,3 tengeri mérfölf)	±15 m (±50 láb)	nem alkalmazható
A kilebegtetés megkezdése egyenetlen terep felett (7.3.2.1.6)			
— 3°-os siklópálya (hagyományos fel- és leszállás)	0	±30 m (±100 láb)	±18 m (±60 láb)
— 6°-os siklópálya (rövid fel- és leszállás)	0	±12 m (±40 láb)	±12 m (±40 láb)
Érzékenység módosulás (7.3.2.1.7)			

C-5. Táblázat (folytatás)

Funkció	Jellemző távolság a küszöbtől	Útvonal-követési hiba (95 %-os valószínűség)	Kormányzási elmozdulási zaj
(robotpilóta erősítés szabályozása)	37 km-től (20 tengeri mérföld) 0-ig	±250 m (±820 láb)	nem alkalmazható
Kilebegtetési manőver MLS kilebegtetési magassággal (7.3.2.1.8)			
— Hagyományos fel- és leszállás	0	±30 m (±100 láb)	±12 m (±40 láb)
— Rövid fel- és leszállás	0	±12 m (±40 láb)	±12 m (±40 láb)
Hosszú kilebegtetési riasztás (7.3.2.1.9)	A futópálya körzete	±30 m (±100 láb)	nem alkalmazható
Hagyományos fel- és leszállás nagysebességű leszállás utáni kifutás / futópálya elhagyás (7.3.2.1.10)	A futópálya körzete	±12 m (±40 láb)	±30 m (±100 láb)
Felszállási emelkedés és megszakított megközelítés	0-tól 9 km-ig (5 tengeri mérföld)	±100 m (±328 láb)	±68 m (±223 láb)
Függőleges fel- és leszállású megközelítések (7.3.2.1.11)	925 m-től (0,5 tengeri mérföld) 0-ig	±12 m (±40 láb)	±12 m (±40 láb)
Koordináta "áttétel" (7.3.2.1.12)	-	±12 m-től ±30 m-ig (±40 láb-tól ±100 láb-ig)	±12 m (±40 láb)

7.3.2.1.8 Az a cél, hogy ezt az előírást alkalmazzák akkor, amikor a függőleges útirány-vezetést és az automatikus leszállás süllyedési mértéket levezetik az MLS kilebegtetési magasságából és a DME / P berendezéstől.

Megjegyzés. - Jóllehet, a szabvány kidolgozásra került az MLS kilebegtetési magassági funkció biztosításához, mégis ez a funkció nem került bevezetésre, és a jövőben sem szándékozunk bevezetni.

7.3.2.1.9 Ez jelzi a légijármű vezetője részére azt, hogy a légijármű a földetérési zónán túl száll le.

7.3.2.1.10 A leszállás utáni kifutási pontossági követelmény a rendszer fejlődési lehetőségeit tükrözi. Ennél az alkalmazásnál a leszállás utáni kifutási útvonal-követési hibát (PFE) annak a lehetőségnek a szükségessége szabja meg, hogy a leszállás utáni kifutási sebesség csökkentését és a futópályáról történő legurulást úgy optimalizálják, hogy az a futópálya foglaltsági idejét csökkentse.

7.3.2.1.11 Az a cél, hogy biztosítsák a légijármű vezetőjét arról, hogy a légijármű a leszállási futópálya felület felett van, mielőtt tovább süllyedne.

7.3.2.1.12 Kívánatos lehet az, hogy az MLS koordinátáit egy kiindulási nulla-pontból a másikba akkor 'tegyék át', amikor az antennák nem a 3. Fejezet 3.11.5.2.6, vagy 3.11.5.3.5 pontjában leírtaknak megfelelően kerültek telepítésre. A táblázatban lévő számadatok a függőleges fel- és leszállási üzemeltetésekre jellemzőek, a tényleges értékek a telepítés geometriájától lesznek függőek.

7.3.3 *A DME / P berendezés hibahalmaza*

A DME / P berendezés 1. és 2. pontossági szabványa hibahalmazainak példáját a C-6. táblázat mutatja be. Amikor a meghatározott hiba összetevőket egyedileg nem haladják meg a hibák a gyakorlatban, akkor elvárható lehet az, hogy elérésre kerül az a teljes rendszer teljesítmény, ami a 3.5.3.1.3.4 pontban előírásra került. A rendszer hiba jelromlási résztvevőjét úgy kell kiszámítani, hogy veszik a meghatározott fedélzet - föld kapcsolatú környezetből kapott hibáknak és a meghatározott föld - fedélzet kapcsolatú környezet hibáknak a négyzetes középértékét (RSS) és leveszik - négyzetes középérték alapon - a jelromlás nélküli környezetből kapott hibákat.

C-6. táblázat: A DME / P berendezés hibahalmazának példája

Hiba-forrás	Hiba összetevő	Végső megközelítési mód 1. Szabvány		Végső megközelítési mód 2. Szabvány		Kezdeti megközelítési mód	
		Útvonal-követési hiba m (láb)	Kormány-zási elmozdulás zaj m (láb)	Útvonal-követési hiba m (láb)	Kormány-zási elmozdulás zaj m (láb)	Útvonal-követési hiba m (láb)	Kormány-zási elmozdulás zaj m (láb)
Belső műszer	Válaszadó	±10 (±33)	±8 (±26)	±5 (±16)	5± (±16)	±15 (±50)	±10 (±33)
	Kérdező	±15 (±50)	±10 (±33)	±7 (±23)	±7 (±23)	±30 (±100)	±15 (±50)
Telepítési helyszín vonatko-zású	Fedélzet - föld kapcsolatú	±10 (±33)	±8 (±26)	±3 (±10)	±3 (±10)	±37 (±121)	±20 ± (66)
	Visszaverőd éses többutas	±10 (±33)	±8 (±26)	±3 (±10)	±3 (±10)	±37 (±121)	±20 (±66)
Telepítési helyszín vonatko-zású	Nem-visszaverődé ses (szóródá-sos) többutas	±3 (±10)	±3 (±10)	±3 (±10)	±3 (±10)	±3 (±10)	±3 (±10)
	Jelromlás (garble)	±6 (±20)	±6 (±20)	±6 (±20)	±6 (±20)	±6 (±20)	±6 (±20)

1. Megjegyzés. - A "nem-visszaverődéses többutas" és a "jelromlás" hibák számjegyei a fedélzet -föld és a föld - fedélzet összetevők összegei.

2. Megjegyzés. - Az útvonal-követési hiba magába foglalja mind a küszöb-beállítási előfeszítés, mind az idő-változói összetevőket. A fenti táblázatban az idő-változói összetevőknél és a legtöbb telepítési helyszíni vonatkozású hibánál elfogadott az, hogy ezek alapvetően statisztikailag függetlenek. A *küszöb-beállítási előfeszítés összetevőt nem lehet összhangba hozni semmilyen meghatározott statisztikai megoszlással.*

Ezeknek a hibahalmazoknak a figyelembevételénél óvatosan kell eljárni az egyedi összetevők bármilyen meghatározott matematikai módszer szerinti összekapcsolásánál.

3. Megjegyzés. - Az adó hullámformájánál 1 200 nanoszekundumos felfutási idő került alapfeltételként elfogadásra.

7.3.4 *A rendszer beállítása*

7.3.4.1 Mivel a DME / P berendezést különféle módon lehet beállítani, a berendezés belső műszer-hibái és a feltételezett terjedési hibái azok a jellemző hibák, amelyek a berendezés felépítéséből eredően hozzáférhetők, azzal, amit a belső időkésleltetési eltérés-helyesbítés lehetősége biztosít, és ami beiktatja az időzítési referencia pont küszöbhelyzetének beállítását egy impulzus-pár első impulzusának a felfutó élén, a következő technikák alkalmazásával:

a) *Kezdeti megközelítési (IA) mód*. Hagyományos technika, ami a küszöböt az 50 százalékos amplitúdó pontnál állítja be.

b) *Végső megközelítési (FA) mód*. Késleltetés-csillapítás és összehasonlítás (DAC) technika, ami a küszöböt az 5 százalékos és 30 százalékos amplitúdó pont közé állítja be.

7.3.4.2 Az 1. pontossági szabványt úgy lehet elérni, hogy egy 100 nanoszekundumos késleltetést és egy, az 5-től a 6 dB-ig terjedő csillapítást alkalmaznak. Az is szükséges még, hogy az amplitúdó küszöbpont mind a késleltetett impulzusnál, mind a csillapított impulzusnál a részleges felfutási időn belülre essen.

7.3.4.3 A fenti példák nem zárják ki azt, hogy a beérkezési idő mérésének technikájánál egy, a késleltetés - csillapítás és összehasonlítás (DAC) technikától eltérő módszert alkalmazzanak, de minden esetben szükséges az, hogy a küszöb-mérések az impulzus részleges felfutási ideje során történjenek meg.

7.3.5 *A DME / P berendezés kérdező jelfeldolgozása*

7.3.5.1 *A befogás során*

a) A kérdező befogja és érvényesíti a jelet 2 másodpercen belül az előtt, mielőtt a követési módra átállna, még akkor is, ha a szomszédos csatornáktól olyan töredék jelek és szabálytalan impulzus-párok fordulnak elő, amelyek 50 százalékos rendszer teljesítményt eredményeznek.

b) A befogott jel elvesztése után mind a kezdeti megközelítési, mind a végső megközelítési módban a kérdező egy másodpercen belül egy figyelmeztető kimenetet ad, amely idő alatt a vezetési információ folyamatosan kijelzésre kerül. A jel elvesztése után a kérdező a kezdeti megközelítési módban visszatér a kereső módba azért, hogy a követést újra létrehozza.

7.3.5.2 *A követő mód során*

7.3.5.2.1 Amikor a követési mód létrejött, akkor a vevő kimeneten érvényes vezetési információk lesznek a figyelmeztető jelzés törlése előtt. Ez az érvényesítési folyamat folyamatosan addig üzemel, ameddig a kérdező adó-vevő a követési módban lesz. A kérdező a követési módban marad addig, amíg a rendszer teljesítmény 50 százalékos, vagy annál nagyobb. A követő mód során a vevő védelmet biztosít a rövid időtartamú, nagy amplitúdójú hibás jelekkel szemben.

7.3.5.3 *Távolság adat szűrő*

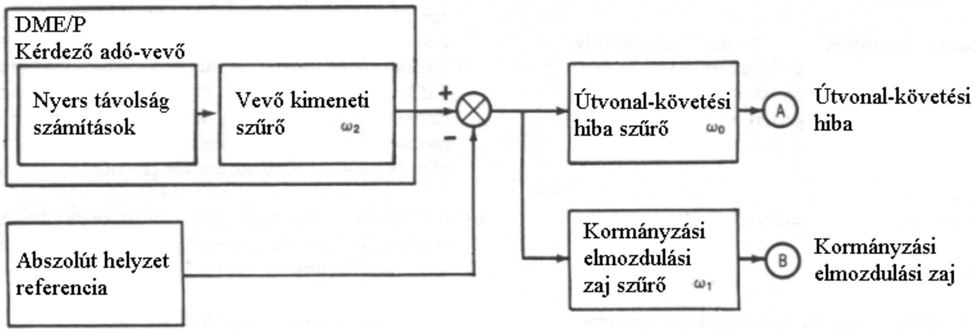
A 3. Fejezet 3.5.3.1.3.4 pontjában leírt pontossági előírásoknál, valamint az előző 7.3.3 pontban tárgyalt hibahalmaznál alapfeltételként elfogadott volt az, hogy a magasabb frekvencia zaj összetevőket egy qw sarok-frekvenciájú aluláteresztő szűrő korlátozza, ahogy az a C-21. számú ábrán meghatározásra került. A felhasználói alkalmazástól függően, a zaj csökkentésére további szűrést lehet felhasználni, feltéve azt, hogy az így létrehozott fáziskésés és amplitúdó eltérés nem fogja károsan befolyásolni a légijármű repülőgép vezérlő rendszerének dinamikus viselkedését. A következő pontokban olyan kiegészítő jellemzőket ajánlunk, amelyeket az adatszűrő berendezésbe kell beépíteni.

7.3.5.4 *Sebességi memória*

Az adatszűrőnél szükség lehet egy sebességi memóriára ahhoz, hogy a 3. Fejezet 3.5.3.1.3.4 pontjában előírt pontosság elérésre kekrüljön az 50 százalékos rendszer teljesítmény mellett. Meg kell jegyezni azt, hogy a kezdeti megközelítési módban az adás azonosítása során alacsony rendszer teljesítmény fordulhat elő.

7.3.5.5 *A 'kívül eső' jelek kiszűrése*

7.3.5.5.1 Azokat a távolsági meghatározásokat, amelyek jelentősen eltérnek a korábbi szűrt távolsági meghatározásoktól, mivel ezek nem lehetnek a légijármű elmozdulásából származó eredmények, hibásnak kell tekinteni. Az ilyen adatokat az adatszűrő berendezéssel ki kell szűrni.



Útirány-vezetési funkció	Sarokfrekvenciák (radián/sec)		
	ω_0	ω_1	ω_2*
DME/P	1.5	0.5	10

Vevő kimeneti szűrő: $\frac{\omega_2}{S + \omega_2}$

Útvonal-követési szűrő: $\frac{\omega_n^2}{S^2 + 2\zeta\,\omega_n\,S + \omega_n^2}$ $\zeta = 1;\ \omega_0 = .64\ \omega_n$

Kormányzási elmozdulási zaj szűrő: $\frac{S}{S + \omega_1}$

* Ezek a sarokfrekvenciák bizonyos berendezéseknél 10 rad/sec-nél kevesebbek lehetnek

	Kezdeti megközelítési mód	Végső megközelítési mód
T	40 másodperc	10 másodperc

C-21. ábra

7.3.6 *A DME / P berendezés hibamérési módszerei*

7.3.6.1 *Rendszer hibák*

7.3.6.1.1 A DME / P berendezés pontosságai a 3. Fejezet 3.5.4.1.3.4 pontjában az útvonal-követési hiba (PFE) és a kormányzási elmozdulási zaj (CMN) értékében kerültek meghatározásra. Ezek a paraméterek a DME / P 'vezető jelei' és a légijármű közötti kölcsönhatást írják le olyan tényezőkben, amelyek közvetlenül vonatkoztathatók a légijármű helymeghatározási hibáira és a repülés vezérlő rendszerek felépítésére.

7.3.6.1.2 A pontossági szabványoknak való megfelelés meghatározása céljából az útvonal-követési hiba (PFE) és a kormányzási elmozdulási zaj (CMN) összetevők egy valamilyen T másodperces időtartamon keresztül (ahol a T = 40 másodperc a kezdeti megközelítési (IA) és 10 másodperc a végső megközelítési (FA) módra) történik úgy, hogy a repülési hibák a DME / P fedésterületi határvonalain belül rögzítésre kerülnek. A 95 százalékos valószínűségi követelményt akkor veszik kielégítettnek, amikor az útvonal-követési hiba (PFE) és a kormányzási elmozdulási zaj (CMN) összetevők nem haladják meg a teljes időtartam alatt az előírt hiba határértékeket, ami az 5 százaléknál több lenne az értékelési időtartamon belül. Ezt a C-21. ábra mutatja be. A DME / P berendezés 'vezető jeleinek' az útvonal-követési hiba (PFE) és a kormányzási elmozdulási zaj (CMN) összetevői értékelésénél a légijármű tényleges helyzete - egy megfelelő helymeghatározási vonatkoztatás szerinti meghatározott helyzete - kerül az egy hibajelet képező vezető jel adataiból kivonásra. Ezt a hibajelet azután az útvonal-követési hiba (PFE) és a kormányzási elmozdulási zaj (CMN) szűrők szűrik, ahol a kimenő jelek az útvonal-követési hiba (PFE) és a kormányzási elmozdulási zaj (CMN) összetevők megfelelő értékelését adják. Ezek a szűrők a C-21.számú ábrán kerültek meghatározásra.

7.3.6.1.3 Ezeket a szűrőket lehet felhasználni a 3. Fejezet 3.5.4.5.3 és 3.5.4.5.4 pontjában meghatározott válaszadó berendezés belső műszerhiba összetevőjének meghatározásához is. Hasonlóképpen lehet a kérdező berendezés belső műszerhiba összetevőit - a 3. Fejezet 3.5.5.4 pontjában meghatározott hibát - is meghatározni.

7.3.7 *Többutas hatások*

7.3.7.1 A valószínűleg előforduló többutas terjedés esetén a DME / P berendezés pontossági előírásai feltételezik azt, hogy a teljesítmény nem csökken le egy meghatározott határérték alá, és azt, hogy ez a csökkenés egyenlő mértékben jelentkezik mind a kérdezőnél, mind a válaszadó vevőjénél.

7.3.7.2 Annak biztosításához, hogy a berendezés az előírások szerint működjön, a rendszer végső megközelítési (FA) módú üzemeltetéséhez a következőket kell alkalmazni:

a) ha egy olyan kielégítő teljesítményű jel kerül alkalmazásra a vevőkre, amelynél a termikus zaj összetevője jelentéktelen, akkor az első jelhez viszonyított 0 és 350 nanoszekundum közötti késleltetésű második jel olyan amplitúdójával, ami 3 dB-el, vagy annál többel az első jel alatt van és a lengési frekvenciája 0,05 és 200 Hz között van, nem hozhat létre a vevő kimenetnél plusz, vagy mínusz 100 nanoszekundumnál (15 m) nagyobb hibákat;

b) a 350 nanoszekundumnál nagyobb késleltetésnél a hiba hozzájárulás jelentős mértékben le fog csökkenni. A jellemző érték a plusz, vagy mínusz 7 nanoszekundum (1 m) lesz.

7.3.7.3 A légijármű fedélzeti DME antennát úgy kell elhelyezni, hogy eleve megakadályozza az előre irányban az antenna-nyereség csökkenését akkor, amikor a légijármű a leszállási helyzetben van. Bármilyen ilyen antenna-nyereség csökkenés megnövelheti a többutas terjedési hiba összetevőt akkor, amikor a légijármű a megközelítési, vagy leszállási szakaszban van, és amikor a legnagyobb DME pontosságra van szükség.

7.3.8 *A DME / P berendezés* teljesítmény szükségleti összetevői

7.3.8.1 A C-7. és a C-8. táblázat példát ad a hagyományos fel- és leszállású levegő - föld és föld - levegő teljesítmény szükséglet összetevőiről. A megengedett kisugárzott teljesítmény csúcsérték azon az impulzus alakon alapszik, ami megfelel a 3. Fejezet 3.5.4.1.3 e) pontban megadott spektrum-korlátozásoknak.

7.3.8.2 A teljesítmény szükséglet összetevőinek számításánál alapfeltételként elfogadott az, hogy a légijrámű antennáját nem árnyékolja le a légijármű sárkány szerkezete, a kibocsájtott helyzetben lévő futóműveket is beleértve.

C-7. táblázat: Hagyományos fel- és leszállású üzemeltetések föld - levegő teljesítmény szükséglet összetevők

A teljesítmény szükséglet összetevők elemei	41 km (22 tengeri mérföld)	13 km (7 tengeri mérföld)	Vonatkoztatási pont	Leszállás utáni kifutás
Kisugárzott csúcs-teljesítmény, dBm	55	55	55	55
Földi többutas terjedési veszteség, dB	-5	-3	-4	-17
Antenna karakterisztika veszteség, dB	-4	-2	-5	-5
Terjedési út veszteség, dB	-125	-115	-107	-103
Ellenőrző rendszer veszteség, dB	-1	-1	-1	-1
Polarizáció és eső miatti veszteség, dB	-1	-1	0	0
A légijárművel vett jel, dBm	-81	-67	-62	-71
Teljesítmény-sűrűség a légijárműnél, dBW/m^2	-89	-75	-70	-79
Légijármű antenna-nyereség, dB	0	0	0	0
Légijárművön belüli tápvonal veszteség, dB	-4	-4	-4	-4
Vett jel a kérdezőnél, dBm	-85	-71	-66	-75
Vevő zaj videó, dBm (Zaj tényező (NF) = 9 dB) Középfrekvenciás sávszélesség: 3,5 MHz Középfrekvenciás sávszélesség: 0,8 MHz	-109	-103	-103	-103
Jel-zaj viszony (videó), dB	24	32	37	28

C-8. táblázat: Hagyományos fel- és leszállású üzemeltetések levegő - föld teljesítmény szükséglet összetevők

A teljesítmény szükséglet összetevők elemei	41 km (22 tengeri mérföld)	13 km (7 tengeri mérföld)	Vonatkoztatási pont	Leszállás utáni kifutás
Kérdező adó teljesítmény, dBm	57	57	57	57
Légijármű antenna-nyereség, dB	0	0	0	0
Légijárművön belüli tápvonal veszteség, dB	-4	-4	-4	-4
Kisugárzott csúcs-teljesítmény, dBm	53	53	53	53
Földi többutas terjedési veszteség, dB	-5	-3	-4	-17
Terjedési út veszteség, dB	-125	-115	-107	-103
Polarizáció és eső miatti veszteség, dB	-1	-1	0	0
A válaszadó antennánál vett jel, dBm	-78	-66	-58	-67
A földi antenna nyeresége, dB	8	8	8	8
Karakterisztika veszteség, dB	-4	-2	-5	-5
Tápvonal veszteség, dB	-3	-3	-3	-3
A válaszadónál vett jel, dBm	-77	-63	-58	-67
Vevő zaj videó, dBm (Zaj tényező (NF) = 9 dB) Középfrekvenciás sávszélesség: 3,5 MHz Középfrekvenciás sávszélesség: 0,8 MHz	-112	-106	-106	-106
Jel-zaj viszony (videó), dB	35	43	48	39

7.3.8.3 A videó teljesítmény jel-zaj viszony a középfrekvenciás teljesítmény jel-zaj viszonyára van vonatkoztatva, a következő módon:

$$\text{Jel / Zaj (videó)} = \text{Jel / Zaj (középfrekvenciás)} + 10 \log \frac{\text{középfrekvenciás zaj sávszélesség}}{\text{videó zaj sávszélesség}}$$

1. Megjegyzés. - A távolságok a válaszadó antennájától vannak mérve.

2. Megjegyzés. - A frekvencia-függő jellemzők 1 088 MHz-re kerültek kiszámításra.

7.3.9 *A DME / P berendezés ellenőrző idő-késleltetésének mérése*

7.3.9.1 A szükséges idő-késleltetés mérést az útvonal-követési hiba (PFE) szűrő kimenetének mérésével lehet elvégezni egy 1 másodpercen belüli döntés szerinti ellenőrző mérés végrehajtásával. Azonban mivel a válaszadó útvonal-követési hibája egy hosszan változó hiba összetevő, ezért egy egyenértékű mérést kell végezni szűrés nélküli idő-késleltetési minták 1 másodperces átlagolásával.

8. Az energia-ellátás átkapcsolási idejére vonatkozó anyag

8.1 A repülőterek körzetében használt földi telepítésű rádiónavigációs berendezések energia-ellátásának átkapcsolási ideje

A rádiónavigációs berendezések és a hírközlési rendszerek földi berendezései energia-ellátásának az átkapcsolási ideje a futópálya típusától függ. A C-9. táblázat mutatja be azokat a jellemző átkapcsolási időket, amelyeknek a jelenleg rendelkezésre álló elektromos energia-ellátó rendszerek meg tudnak felelni.

C-9. táblázat: A repülőtereken használt földi telepítésű rádiónavigációs berendezések energia-ellátásának átkapcsolási ideje

A futópálya típusa	Az energia-ellátást igénylő berendezés	Maximális átkapcsolási idő (másodperc)
Műszeres megközelítés	SRE VOR NDB Iránymérő (D/F) berendezés	15 15 15 15
Precíziós megközelítés I. Kategória	ILS iránysáv ILS siklópálya ILS középső helyjeladó ILS külső helyjeladó PAR	10 10 10 10 10
Precíziós megközelítés II. Kategória	ILS iránysáv ILS siklópálya ILS belső helyjeladó ILS középső helyjeladó ILS külső helyjeladó	0 0 1 1 10
Precíziós megközelítés III. Kategória	(ugyanaz, mint a II. kategóriánál)	

„D" MELLÉKLET: TÁJÉKOZTATÁS ÉS ÚTMUTATÓ ANYAG A GLOBÁLIS NAVIGÁCIÓS MŰHOLD RENDSZER (GNSS) SZABVÁNYAINAK ÉS AJÁNLOTT GYAKORLATAINAK ALKALMAZÁSÁHOZ

1. Meghatározások

Bi-bináris ***/Bi-binary/.*** A bi-bináris kódolás „Manchester kódolás"-ként ismeretes. Erre néha úgy is utalnak, mint „Differenciál Manchester kódolás"-ra. Ezt a rendszert használva az él átmenet az, ami a bitet meghatározza.

Chip ***/Chip/.*** Egy egyedüli digitális bit az ál-véletlen bit jelsorozat kimenetén.

Gold kód ***/Gold code/.*** Azoknak a GPS által használt egyedülálló kódoknak a kategóriája, amelyek feltárják a korlátozott kereszt-korrelációs és a csúcson-kívüli auto-korrelációs értékeket.

Szelektív rendelkezésre állás (SA) ***/Selective availability (SA)/.*** A technikai megoldások egy sorozata a teljes pontosság visszautasítására és a helymeghatározás a sebesség és az idő pontosság szintjének kiválasztására, a felhasználók részére rendelkezésre álló GPS szabvány helymeghatározási szolgáltatási jelénél.

Megjegyzés. – A Globális Helymeghatározó Rendszer /GPS/ Szelektív rendelkezésre állása /SA/ 2000. május 1-jének éjjelén megszűntetésre került.

2. Általános

A GNSS-re vonatkozó Szabványok és Ajánlott Gyakorlatok magukba foglalják a 3. Fejezet 3.7.2.2 pontjában azonosított alkotóelemekre vonatkozó előírásokat.

3. Navigációs rendszer teljesítmény követelmények

3.1 Bevezetés

3.1.1 A navigációs rendszerek teljesítmény követelményei a *Szükséges Navigációs Teljesítmény (RNP) Kézikönyv*-ben (Doc 9613) és a *Megközelítési, Leszállási és Indulási Üzemeletetésekhez Szükséges Navigációs Teljesítmény (RNP) Kézikönyv*-ben (előkészületben) vannak meghatározva egy egyedüli légijárműre és a teljes rendszerre, ami magába foglalja a térbeli-jelet, a légijármű fedélzeti berendezését és a légijármű azon képességét, hogy végigrepülje a megkívánt 'pályagörbét'. Ezek a teljes rendszer követelmények kerültek kiindulási pontként felhasználásra a Globális Navigációs Műhold Rendszer /GNSS/ térbeli-jel teljesítmény követelményeinek származtatására. A GNSS esetében azok a csökkentő konfigurációk, amelyek hatással lehetnek a többszörös légijárművekre /multiple aircraft/, figyelembe vételre kerültek. Ennek megfelelően, bizonyos térbeli-jel teljesítmény követelmények jóval szigorúbbak a rendszer többszörös légijárművek általi felhasználását számításba véve.

3.1.2 A Függőleges Vezérléssel /APV/ végrehajtott megközelítések két típusa, az APV-I. és az APV-II. használ fel függőleges vezetést a siklópályához viszonyítva, de a berendezés, vagy a navigációs rendszer nem elégíti ki a precíziós megközelítéshez kapcsolódó összes követelményt. Ezek az üzemeltetések összekapcsolják azt az oldalirányú teljesítményt, ami egyenlő az ILS I. kategóriájú iránysávadóra vonatkozó követelményekkel a függőleges vezetés különböző szintjeivel együtt. Mindkét, az APV-I. és az APV-II. biztosítanak megközelítési előnyöket egy nem-precíziós megközelítéshez viszonyítva, és az a szolgáltatás, amit nyújtanak, az üzemeltetési követelményektől és a Műhold Bázisú Kiegészítő Rendszer /SBAS/ infrastruktúrájától függ. Az APV-I. és az APV-II. meghaladja a jelenlegi Területi Navigációs /RNAV/ barometrikus magasságmérőt felhasználó megközelítések (oldalirányú és függőleges) követelményeit, és a vonatkozó fedélzeti berendezések ennek megfelelően alkalmasak lesznek a barometrikus VNAV függőleges vezetéssel végrehajtott egközelítésekre /APV/ és az RNAV nem-precíziós megközelítésekre.

3.2 Pontosság

3.2.1 A GNSS helyzet hiba a számított helyzet és a tényleges helyzet közötti különbség. Egy meghatározott helynél a számított helyzetre a valószínűségnek legalább 95 százaléknak kell lennie annak, hogy a helyzet hiba a pontossági követelményen belül van.

3.2.2 Az állandó-helyű, föld-bázisú rendszereknek – mint például a VOR-nak és az ILS-nek – viszonylag ismétlődő hiba jellemzőjük van, úgy, hogy a teljesítményük egy rövid időtartam során mérhető (például a légi ellenőrzés során) és elfogadott az, hogy a rendszer pontossága az ellenőrzés után nem fog változni. Azonban, a GNSS hibák állandóan változnak. A keringő műholdak és a GNSS hiba jellemzői olyan helyzet hibákat eredményeznek, amelyek egy egy-órás időtartam alatt is megváltoznak. Azonkívül még, maga a pontosság (a hibahatár a 95 százalékos valószínűséggel) is változik az eltérő műhold elrendezés miatt. Mivel nem lehetséges az, hogy a rendszer pontosság folyamatosan mérésre kerüljön, a GNSS ’kivitelezése’ megnövekedett bizalmat követel meg a hibák elemzésében és a karakterizálásában. Egy ’csúszó-idejű ablakon’ belüli méréseken alapuló értékelés a GNSS-re nem alkalmas.

3.2.3 Több GNSS rendszer hibája az idővel lassan változik, a kiegészítő rendszerekben és a felhasználói vevőkben lévő szűrés miatt. Ez egy néhány-perces időtartamon belül kisszámú önálló mintát eredményez. Ez a kérdés nagyon fontos a precíziós megközelítési alkalmazásnál, mivel ez foglalja magába azt, hogy van egy olyan 5 százalékos valószínűség, amikor a helyzet hiba meghaladhatja a megközelítéshez szükséges teljes pontosságot. Azonban a 3.2.2 pontban leírt változó pontosság miatt ez a valószínűség általában jóval alacsonyabb.

3.2.4 A 95 százalékos pontossági követelmény úgy van meghatározva, hogy ez biztosítja a légijárművezető általi elfogadást, mivel ez azt a hibát képviseli, amit jellemzően tapasztalni is fog. A GNSS pontossági követelmény meg kell, hogy feleljen annak a legrosszabb helyzetű geometriának, amely mellett a rendszert használhatónak nyilvánították. A statisztikai, vagy valószínűségi bizalmat nem tartják egy adott távolságmérési jel geometriánál valószínűségi alapnak.

3.2.5 Ennek megfelelően a GNSS pontossága úgy került meghatározásra, mint az egyes és minden egyes minta valószínűsége, és nem úgy, mint a minták százaléka egy meghatározott mérési időtartamban. Az önálló minták egy nagy sorozatánál legalább a minták 95 százalékának a 3. Fejezet 3.7.2.4-1. táblázatában megadott pontossági követelményeken belül kell lenni. Az adat a legrosszabb esetű geometriához van mérve abból a célból, hogy a keringő műholdak geometriája által okozott rendszer pontosság változékonyságot kiküszöböljék.

3.2.6 Egy példa arra, hogy ezt az elvet hogyan lehet alkalmazni a nem-precíziós megközelítési üzemeltetésekhez szükséges teljesítménynek a GPS-el történő alátámasztásra. Tegyük fel azt, hogy a rendszer olyan nem-precíziós megközelítések alátámasztására tervezett, amikor a precíziós pontosság vízszintes gyengítése (HDOP) 6-nál kisebb, vagy avval egyenlő. Ennek a teljesítménynek a bemutatására mintákat kell venni egy hosszabb időtartamon keresztül (például 24 órán át). A mért helyzet hiba, a *g*, az egyes *i* mintákra, *gi*-ként kerül jelzésre. Ez a hiba a legrosszabb esetű geometriához van mérve, mint 6×g*i*/HDOP. A mért hibák kilencvenöt százalékának 220 méternél kevesebbnek kell lenni ahhoz, hogy a rendszer kielégítse a nem-precíziós pontossági követelményeket a legrosszabb esetű geometriájú körülményeknél. Az összegyűjtött minták teljes számának elegendőnek kell lenni ahhoz, hogy az eredmény statisztikailag jellemző legyen, a hibák dekorrelációs idejét számításba véve.

3.2.7 A függőleges pontossági értékek egy sorozata került az I.Kategóriájú precíziós megközelítési üzemeltetésekre meghatározásra, azok, melyek összekötik azokat a különféle értékeket, amelyek alátámaszthatnak egy, az ILS-el egyenlő értékű üzemeltetést. A számos érték különböző csoportokból származik, az ILS szabványok különféle értelmezését felhasználva. Ezekből a származtatásokból a legalacsonyabb értékek kerültek elfogadásra egy konzervatív értékként a GNSS-re, ez a minimális érték van a távolságra megadva. Mivel ez az érték konzervatív, és mivel a Globális Navigációs Műhold Rendszer /GNSS/ hiba jellemzői eltérnek az ILS-étől, lehetséges, hogy az I. Kategóriájú üzemeltetéseket el lehet érni a pontosság és a riasztási határértékek nagyobb értékeinek alkalmazásával a tartományon belül. A nagyobb értékek megnövekedett elérhetőséget eredményeznének az üzemeltetésekre. A tartomány maximális értékei kerültek ajánlásra megfelelő értékekként, az érvényesítéstől függően.

3.2.8 Speciális riasztási határértékek kerültek meghatározásra az egyes kiegészítő rendszerekre. A Földi Bázisú Kiegészítő Rendszernél /GBAS/ műszaki előírások határozzák meg a légijárművek részére történő riasztási érték sugárzását. A GBAS szabványok 10 méteres riasztási határértéket követelnek meg. A Műhold Bázisú Kiegészítő Rendszerre /SBAS/ műszaki előírások határozzák meg a riasztási határérték szabványosítását egy felfrissíthető adatbázison keresztül (lásd a *Minimális Üzemeltetési Teljesítmény Szabványok a Globális Helymeghatározó Rendszer/Nagy Kiterjedésű Kiegészítő Rendszer- (GPS/WAAS)-re Légijármű Fedélzeti Berendezés-* (RTCA/DO-229C)-t).

3.2.9 A GPS SPS pozíció hiba (lásd 3. Fejezet 3.7.3.1.1.1 pontot) a pozíció hibák (műhold óra és efemerisz hibák) közül csak a világűr és a vezérlés részbe számít bele; nem tartozik bele az ionoszférikus és troposzférikus késleltetési modell hibákba, a többutas hatások miatt keletkező hibákba és a vevő mérési-zaj hibákba (”D”- Melléklet, 4.1.2 pont). Ezek a hibák a vevő szabványokban vannak megemlítve. Az ABAS-képességgel rendelkező berendezés kimenetén mérhető felhasználói helyzetmeghatározási hibát főleg a felhsznált GNSS vevő okozza.

3.2.9.1 Az Alapvető GNSS vevőknél a vevő minősítési szabványok megkövetelik a felhasználói helyzetmeghatározási pontosság meglétét interferencia megléte esetén egy szelektíven rendelkezésre álló modellnél (SA), ami vízszintesen kevesebb, mint 100m (az idő 95 százalékában) és függőlegesen 156m (az idő 95 százalékában). A vevő szabványok nem követelik meg, hogy egy Alapvető GNSS vevő a ”B”- Függelék, 3.1.2.4 pontjában lefektetett ionoszférikus korrekciót alkalmazzon.

Megjegyzés. – Az ’Alapvető GNSS vevő’ meghatározás egy olyan GNSS repülő elektronikát jelent, mely minimálisan megfelel annak a GPS vevő követelményeinek, amit az Annex 10, I. kötet, valamint az Egyesült Államok Szövetségi Légügyi Hivatal (FAA) által módosított RTCA/DO-208 dokumentum (TSO-C129A) műszaki meghatározásai ismertet, vagy amit az EUROCAE ED-72-A (vagy annak megfelelő) tartalmaz.

3.2.9.2 A szelektív rendelkezésre állás (SA) szüneteltetése miatt a GPS reprezentatív felhasználói helyzetmeghatározási pontosságát körültekintően a D-0. Táblázatban látható módon állapítják meg. A számok azt feltételezik, hogy a névlegesen 24 GPS műholdból a legrosszabb esetben két műhold elromlott. Ráadásul, egy 7m-es (1 σ) ionoszférikus késleltetési modell hibát, egy 0,25m-es (1 σ) maradék troposzférikus késleltetési hibát és egy 0,80m-es (1 σ) vevő zaj hibát feltételeztek. A szelektív rendelkezésre állás (SA) szüneteltetése után (”D”- Melléklet, 1. pont) a túlsúlyban levő pszeudó-távolsági hiba a GPS Állandó Helyzetmeghatározó Szolgálat felhasználói számára az az ionoszférikus hiba lesz, ami az ionoszférikus korrekciók alkalmazása után marad. Ez a hiba szintén nagyon változó és olyan feltételektől függ, mint a felhasználói földmágneses földrajzi szélesség, a naptevékenység szintje (azaz a napciklus), az ionoszférikus aktivitás szintje (azaz van-e mágneses

vihar, vagy nincs), a pszeudó-távolsági mérés tengerszint feletti magassági szöge, az évszak és a napszak.
A 0. Táblázatban szereplő feltételezett ionoszférikus késleltetési modell hiba általánosságban óvatos számításon alapszik, ennek ellenére léteznek olyan feltételek, amikor a feltételezett 7m (1 σ) hiba a maximális naptevékenység alatt nem megfelelő.

D-0. Táblázat: GPS felhasználói helyzetmeghatározási pontosság

	GPS felhasználói helyzetmeghatározási pontosság az idő 95%-ában, átfogó átlag
Vízszintes helyzetmeghatározási hiba	33m (108 láb)
Függőleges helyzetmeghatározási hiba	73m (240 láb)

3.2.10 A Műhold Bázisú Kiegészítő Rendszer (SBAS) és a Földi Bázisú Kiegészítő Rendszer (GBAS) vevői sokkal pontosabbak, a pontosságukat valós időben a szabványos hiba modelleket használó vevő jellemzi, ahogy a 3. Fejezet 3,5 pontja tartalmazza az SBAS számára, valamint a 3. Fejezet 3,6 pontja a GBAS számára.

1. Megjegyzés. - Az 'SBAS vevő' meghatározás egy olyan GNSS repülő elektronikát jelent, mely minimálisan megfelel annak az SBAS vevő követelményeinek, amit az Annex 10, I. kötet, valamint az Egyesült Államok Szövetségi Légügyi Hivatal (FAA) által módosított RTCA/DO-229C dokumentum (TSO-C145A/TSO-C146A) műszaki meghatározásai ismertet, (vagy annak megfelelő).

2. Megjegyzés. - A 'GBAS vevő' meghatározás egy olyan GNSS repülő elektronikát jelent, mely minimálisan megfelel annak a GBAS vevő követelményeinek, amit az Annex 10, I. kötet, valamint az Egyesült Államok Szövetségi Légügyi Hivatal (FAA) által módosított RTCA/DO-253A dokumentum (TSO-C161 és TSO-C162) műszaki meghatározásai ismertet, (vagy annak megfelelő).

3.3 Sértetlenség és idő-a-riasztásig

3.3.1 A sértetlenség annak a bizalomnak a mértéke, amelyet a teljes rendszer által biztosított információ pontosságára lehet helyezni. A sértetlenség magába foglalja a rendszernek azt a képességét, hogy a kellő időben és érvényesen figyelmeztetéseket biztosít a felhasználó számára (riasztások), amikor a rendszert nem szabad a tervezett üzemeltetésre felhasználni (vagy a repülés szakaszára).

3.3.2 Annak biztosításához, hogy a helyzet hiba elfogadható legyen, egy olyan riasztási határérték került meghatározásra, ami a biztonságos üzemeltetéshez megengedhető legnagyobb helyzet hibát képviseli. A helyzet hiba nem lépheti túl ezt a riasztási határértéket annak közlése nélkül. Ez analóg az ILS-el, mivel akkor is lecsökkenhet a rendszer úgy, hogy a hiba nagyobb, mint a 95 százalékos érték, de az ellenőrző berendezés határértékein belül.

3.3.3 A navigációs rendszer sértetlenségi követelménye az, hogy egy egyedüli légijármű részére az útvonal, a közelkörzeti, a kezdeti megközelítési, a nem-precíziós megközelítési és az indulási repülésben alátámasztást biztosítson $1 - 1 \times 10^{-5}$ óránkénti értékként elfogadva.

3.3.4 A műhold-bázisú navigációs rendszernél a térbeli-jel az útvonal repülési környezetben egyidejűleg nagy számú légijármű nagy területen történő kiszolgálására szolgál, és a rendszer sértetlenségi hiba hatása a légiforgalom vezetési rendszerére nagyobb lesz, mint a hagyományos navigációs rendszereké. A 3. Fejezet 3.7.2.4-l táblázatában lévő teljesítmény követelmények ennek megfelelően jóval nagyobb követelményűek.

3.3.5 A precíziós megközelítési üzemeltetésekre a sértetlenségi követelmények a Globális Navigációs Műhold Rendszer /GNSS/ térbeli-jel követelményeire a 3. Fejezet 3.7.2.4-l táblázatba úgy kerültek kiválasztásra, hogy megegyeznek az ILS követelményekkel.

3.4 A szolgáltatás folyamatossága

3.4.1 A szolgáltatás folyamatossága a rendszernek az a képessége, hogy a feladatát nem-tervezett megszakítások nélkül hajtsa végre a tervezett üzemeltetése során.

3.4.2 *Útvonal repülés*

3.4.2.1 Az útvonal repülési üzemeltetésekre a szolgáltatás folyamatossága a navigációs rendszer azon képességére vonatkozik, hogy navigációs jel kimenetet biztosítson az előírt pontossággal és sértetlenséggel a tervezett üzemeltetés teljes egészében, feltételezve azt, hogy az üzemeltetés kezdeténél rendelkezésre állt. A navigációs rendszer riasztásainak előfordulásai – vagy a ritka hibamentes teljesítmény miatt, vagy a hibák miatt – képezik a folyamatossági hibákat. Mivel az ilyen működéseknek az időtartama változó, a folyamatossági követelmény a valószínűség óránkénti előfordulása alapján került meghatározásra.

3.4.2.2 A navigációs rendszer folyamatossági követelménye egy egyedi légijármű részére $1 - 1 \times 10^{-4}$ óránként. Azonban a műhold-bázisú rendszer térbeli-jele nagy számú légijárművet egy nagy területen belül szolgál ki. A 3. Fejezet 3.7.2.4-l táblázatában megadott folyamatossági követelmények képviselik a GNSS-re vonatkozó térbeli-jel követelményeket, azaz ezekből erednek a leállások közötti átlagos idő (MTBO) követelmények a GNSS rendszer alkotó-elemeire.

3.4.2.3 Egy értéktartomány került a 3. Fejezet 3.7.2.4-l táblázatában megadásra a térbeli-jel folyamatossági követelményeire az útvonal repülési üzemeltetésekhez. Az alacsonyabb érték az a minimális folyamatosság, amelynél a rendszert gyakorlatilag használhatónak tekintjük. Ez az olyan területekre megfelelő, ahol alacsony a forgalom sűrűsége, és kicsi a légtér összetettsége. Az ilyen területeken a navigációs rendszer hibájának hatása kevés légijárműre korlátozódik, és ennek megfelelően nincs szükség a folyamatossági követelmény jelentős növelésére az egy egyedüli légijárműre vonatkozó ($1 - 1 \times 10^{-4}$ óránként) követelményen túl. A megadott legmagasabb érték (azaz az $1 - 1 \times 10^{-8}$ óránként) az olyan területekre megfelelő, ahol nagy a forgalom sűrűsége és a légtér összetettsége, ahol a hiba sok légijárművet fog érinteni. Ez az érték az olyan navigációs rendszerekre megfelelő, ahol nagyfokú a navigációs rendszer megbízhatósága iránti és a lehetséges légtér-ellenőrzés iránti igény. Ez az érték megfelelően magas ahhoz a várható helyzethez, ami a rendszer élettartama során bekövetkező kis valószínűségű rendszer hibán alapszik. A folyamatosság középső értékeit (például
$1 - 1 \times 10^{-6}$ óránként) megfelelőnek tartjuk az olyan területekre, ahol nagy a forgalom sűrűség és a légtér összetettség, és ahol nagyfokú a navigációs rendszer megbízhatósága iránti igény, de amelyben a navigációs rendszer meghibásodásai miatti ’csökkenés’ lehetséges. Az ilyen ’csökkenés’ lehetséges az alternatív navigációs eszközök felhasználása miatt, vagy az ATC légtér-felderítésének felhasználásával és az elkülönítési minimumok beavatkozásos fenntartásával. A folyamatossági teljesítmény értékei a légtér szükségleteinek megfelelően került meghatározásra a navigációs alátámasztásra ott, ahol a Globális Navigációs Műhold Rendszer /GNSS/ vagy a meglévő navigációs berendezés infrastruktúrát helyettesíti, vagy ahol ilyen infrastruktúra a korábbiakban nem létezett.

3.4.3 *Megközelítés és leszállás*

3.4.3.1 A megközelítési és leszállási üzemeltetésekhez a szolgáltatás folyamatossága a navigációs rendszer azon képességére vonatkozik, hogy navigációs jel kimenetet biztosítson az előírt pontossággal és sértetlenséggel a megközelítés során, feltételezve azt, hogy az üzemeltetés kezdeténél rendelkezésre állt. A navigációs rendszer riasztásainak előfordulásai – vagy a ritka hibamentes teljesítmény miatt, vagy a hibák miatt – képezik a folyamatossági hibákat. Ebben az esetben a folyamatossági követelmény egy rövid sugárzási idő valószínűségeként került meghatározásra.

3.4.3.2 A megközelítési és leszállási műveletek folyamatossági követelményeit csak a követelményeknek a légijármű fedélzeti vevő és a rendszer nem-légijármű fedélzeti elemei közötti szétosztása jeleníti meg. Eben az esetben nem tartják szükségesnek a követelménybeli növelést a rendszernek a több légijármű általi felhasználásához kapcsolódóan. A folyamatossági érték elfogadottan csak a megszakított megközelítéshez kapcsolódó kockázatra vonatkozik, és minden egyes légijárművet függetlennek lehet tekinteni. Azonban néhány esetben szükség lehet a folyamatossági értékek növelésére, tekintettel arra, hogy egy rendszer hibát két futópálya között kell összefüggésbe hozni (azaz az egymáshoz közel elhelyezkedő, párhuzamos futópályákra történő megközelítéseknél egy közös megközelítési rendszer alkalmazása esetén).

3.5 Rendelkezésre állás

3.5.1 A Globális Navigációs Műhold Rendszer /GNSS/ rendelkezésre állását a rendszer navigációs célokra történő felhasználási idejének azon része adja, amely során megbízható navigációs információkat biztosít a légijármű személyzete, a robotpilóta, vagy más repülés vezérlő rendszer részére.

3.5.2 Amikor a GNSS rendelkezésre állási követelményének megállapítása történik, akkor az alátámasztott szolgáltatás megkívánt szintjét kell figyelembe venni. Ha a műholdas navigációs szolgáltatás tervezett felhasználása egy meglévő útvonal navigációs berendezés infrastruktúra helyettesítése, akkor a GNSS-t azzal a rendelkezésre állással kell összevetni, amelyet a meglévő infrastruktúra biztosított. A szolgáltatás csökkenés üzemeltetési hatásának kiértékelését el kell végezni.

3.5.3 Ahol a GNSS rendelkezésre állása alacsony, még ot is lehetséges a műholdas navigációs szolgáltatás felhasználása, a navigációs üzemeltetési időnek arra az időtartamára történő korlátozásával, amikor a rendszer előreláthatóan rendelkezésre fog állni. Ez abban az esetben lehetséges, ha a GNSS alkalmatlansága a nem kielégítő műhold állás miatt ismétlődően jelentkező. Az ilyen korlátozások mellett csak az a folyamatossági kockázat marad, ami a szükséges rendszer összetevők hibájához kapcsolódóan az előrelátható idő jelzése és az üzemeltetés végrehajtásának ideje között áll fenn.

3.5.4 *Útvonal repülés*

3.5.4.1 Egy területre, vagy üzemeltetésre a jellemző rendelkezésre állási követelményeknek a következőkön kell alapulni:

a) A forgalom sűrűsége és összetettsége;

b) Az alternatív navigációs berendezések;
c) Az elsődleges/másodlagos légtér-felderítés fedése;

d) A légiforgalmi és a légijármű vezetési repülési eljárások; és

e) A kényszer-kiesések időtartama.

3.5.4.2 Ebből az okból, a Globális Navigációs Műhold Rendszer /GNSS/ Szabványok és Ajánlott Gyakorlatok /SARPs/ egy érték sorozatot határoz meg a rendelkezésre állási követelményekre. A követelmény az, hogy a légtérben a GNSS alátámassza az egyedüli-eszközű üzemeltetéseket a forgalom különféle szintje és összetettsége esetén. Az érték tartomány alsó vége csak annyi, hogy a rendszer kielégítő legyen a kis forgalom sűrűségű és összetettségű légtérben az egyedüli-eszközű navigáció biztosításához.

3.5.4.3 Miközben a kiegészítő rendszerek csökkenteni tudják a GNSS függőséget egy meghatározott műhold-sor elemre, ugyanakkor nem biztosítanak használható szolgáltatást a műhold-sor elemek nélkül. Egy területen belül egy meghatározott kiegészítő rendszer rendelkezésre állási követelményeinél számításba kell venni a GNSS műhold-sor elemeknek azt a lehetséges teljesítőképesség csökkenését (azaz a műhold-sor elemek minimális konstellációját (a műholdak számát és különféleségét), ami elvárható).
Üzemeltetési eljárásokat kell kidolgozni az ilyen esetre, amikor a teljesítőképesség csökkenéses konfiguráció előfordul.

3.5.5 *Megközelítés*

3.5.5.1 Az egy területre jellemző követelményeket a következőkre kell alapozni:

a) A forgalom sűrűsége és összetettsége;

b) Az egy kitérő repülőtérre történő megközelítéshez való elrepülés és ott a megközelítés végrehajtásának eljárásai;

c) A kitérő repülőtéren használandó navigációs rendszer;

d) A légiforgalmi és a légijármű vezetési eljárások;

e) A kényszer-kiesések időtartama; és

f) A kényszer-kiesések földrajzi kiterjedése.

3.5.5.2 Amikor a GNSS-re alapozott megközelítési rendszerek üzemeltetési eljárásait kidolgozzák, akkor egy kényszer-kiesés időtartamát és annak a kitérő repülőtérre való hatását figyelembe kell venni. Jóllehet, olyan GNSS kényszer-kiesések fordulhatnak elő, amelyek számos megközelítésre hatással lehetnek, a megközelítés szolgáltatását mindenféle karbantartási művelet nélkül helyre lehet állítani a műholdak keringése miatt.

3.5.6 *A Globális Navigációs Műhold Rendszer /GNSS/ rendelkezésre állásának meghatározása*

A GNSS rendelkezésre állása bonyolult kérdés a műholdaknak az egy figyelembe vett területhez viszonyított mozgása miatt, és mivel potenciálisan hosszú idő szükséges egy műholdnak a meghibásodása esetén annak kijavítására. A rendelkezésre állás pontos méréséhez több évre lenne szükség ahhoz, hogy lehetővé váljon egy Meghibásodások Közötti Átlagos Idő /MTBF/ és a javítási időknél hosszabb mérési időtartam. A GNSS rendelkezésre állását inkább a tervezéssel, az elemzéssel és a modellezéssel lehet meghatározni, nem pedig méréssel. A 3. Fejezet 3.7.2.4 pontjában meghatározott rendelkezésre állást, mint tervezési rendelkezésre állást kell alkalmazni.

Megjegyzés. – A rádióösszeköttetések és a navigációs berendezések megbízhatóságához és rendelkezésre állásához tartozó kiegészítő útmutató anyagot az „F”- Melléklet tartalmazza.

4. A Globális Navigációs Műhold Rendszer /GNSS/ alkotó-elemei

4.1 Globális Helymeghatározó Rendszer /GPS/

Megjegyzés. – A GPS-re vonatkozó kiegészítő tájékoztatásokat a „Globális Helymeghatározó Rendszer Szabvány Helymeghatározási Szolgáltatás – Teljesítmény Szabvány", 2001. október, valamint az Interfész Vezérlési Dokumentum (ICD)-GPS-200C című anyagban lehet találni.

4.1.1 A teljesítmény szabványok arra az alap-feltételre alapozottak, hogy egy reprezentatív Szabvány Helymeghatározási Szolgáltatású /SPS/ vevő kerül felhasználásra. A reprezentatív vevőnek a következők a jellemzői: az ICD-GPS-200C-nek megfelelően került megtervezésre; egy 5-fokos fedő szöget használ; a műhold helyzet és a geometriai távolság számítások végrehajtásánál a Geodéziai Világrendszer – 1984 (WGS-84) Föld-Központú, Föld-Állandójú (ECEF) koordináta rendszer legfrissebb kialakítását használja fel; az összes, hatóterében lévő műhold adataiból összeállítja a helyzet és idő megoldást; kiegyenlíti a dinamikus Doppler-eltolódás hatását a névleges Szabvány Helymeghatározási Szolgáltatás /SPS/ távolság-mérési jel vivő bázisán és a Torzított /Durva/ Hozzáférési /C/A/ kód méréseknél kizárja a GPS nem megfelelő működési állapotú műholdakat a helyzet megoldásból; felhasználja a legújabb és a belsőleg megegyező efemerisz és idő adatokat az összes olyan műholdra, amelyet a helyzet megoldásához felhasznál; és elveti a nyomkövetést abban az esetben, ha egy GPS műhold leállítja a C/A kódjának sugárzását. Az idő átviteli pontosság egy olyan 'helyhez' kötött vevőre vonatkozik, ami egy geodéziailag felmért helyen működik. Egy 12-csatornás vevő ki fogja elégíteni a 3. Fejezet 3.7.3.1.1.1 és 3.7.3.1.2 pontjában meghatározott teljesítmény követelményeket. Egy olyan vevő, amely csak négy műholdat képes követni ("B"- Függelék 3.1.3.1.2) nem fogja elérni a teljes pontossági és rendelkezésre állási teljesítményt.

4.1.2 *Pontosság.* A pontosság egy reprezentatív vevővel kerül mérésre, és egy 24 órás mérési időtartamon keresztül a fedésterület bármely pontján belül. A helymeghatározási és időmérési pontosság csak a térbeli-jelet (SIS) foglalja magába, és nem épít be olyan hibaforrásokat, mint az ionoszféra, a troposzféra, az interferencia, a vevő-zaj vagy a többutas hatás. A pontosság levezetése azon alapszik, hogy a 24 műholdas műhold-rendszerből a legrosszabb két műholdat, valamint a 6 méteres műhold-rendszer RMS térbeli-jel /SIS/ felhasználói távolságmérési hibát (URE) nem veszik figyelembe.

4.1.3 *Távolság tartomány pontosság.* A távolság tartomány pontosságot egy olyan műhold szabja meg, amely jó működési állapotot /healthy/ és Torzított /Durva/ Hozzáférési /C/A/ kódot jelez, és nem számít bele a szabályos üzemelési jellemzőin kívüli műhold hibákba. A távolság pontossági határértékeket túl lehet lépni a műhold hibák, vagy anomáliák során, miközben az adatokat a műholdba betáplálják. A távolság hibahatárok kimagasló értéke egy nagyobb szolgáltatási hibát eredményez, ahogy az a 4.1.6 pontban leírásra került. A sebesség távolság hibahatár a maximum bármely műholdra bármely 3-másodperces időtartamon keresztül és a fedésterületen belüli bármelyik ponton mérve. A távolság gyorsulási hibahatár a maximum bármely műholdra bármely 3-másodperces időtartamon keresztül és a fedésterületen belüli bármelyik ponton mérve. A négyzetes középértékű távolság hiba pontosság, az RMS Felhasználói Távolságmérési Hiba /URE/ átlaga az összes műholdra egy 24 órás időtartamon keresztül, a fedésterületen belüli bármely pontra mérve. Szabályos körülmények esetén az összes műhold megtartja ugyanazokat a szabványokat, úgy, hogy a rendelkezésre állás modelezés céljából alkalmas annak feltételezésére, hogy az összes műhold RMS térbeli-jel felhasználói távolság hibája /SIS URE/ 6 méter. A szabványok azokra távolság tartási hibákra korlátozottak, amelyek a térbeli és vezérlési szegmensekre engedélyezettek.

4.1.4 *Rendelkezésre állás.* A rendelkezésre állás egy bármely 24 órás időtartam idejének a százaléka, amikor az előre meghatározható 95 százalékos helymeghatározási hiba (a térbeli és vezérlési szegmens hibái miatt) a küszöb értékénél kevesebb, a fedésterületen belül bármely ponton. Ez egy 36 méteres vízszintes 95 százalékos küszöbön alapszik; egy 77 méteres függőleges 95 százalékos küszöbön; egy reprezentatív vevő felhasználásával; és bármely 24 órás időtartamon a fedésterületen belül működően értendő. A szolgáltatás rendelkezésre állás feltételezi azt a legrosszabb kombinációt, hogy két műhold üzemképtelen.

4.1.4.1 *Összefüggés a kiegészítő rendszerek rendelkezésre állásáról.* A Légijármű Bázisú Kiegészítő Rendszer /ABAS/, a Földi Bázisú Kiegészítő Rendszer /GBAS/ és a Műhold Bázisú Kiegészítő Rendszer /SBAS/ rendelkezésre állásának nincs közvetlen összefüggése a 3. Fejezet 3.7.3.1.2 pontjában meghatározott GPS rendelkezésre állásra. Az Államoknak és az üzemeltetőknek kell kiértékelni a kiegészítő rendszerek rendelkezésre állását a követelményekhez kapcsolódó kiegészítő teljesítménnyel történő összehasonlítással. A rendelkezésre állás elemzése egy alapfeltételként elfogadott műhold rendszeren alapszik, és azon a valószínűségen, hogy egy adott számú műhold van. 24 működő műhold áll rendelkezésre a műhold-pályán, 0,95 valószínűséggel (átlagolva bármely napra), ahol egy műhold akkor van működőképesként meghatározva, ha az képes – de nem szükségszerű, hogy sugározza is – egy felhasználói távolság meghatározási jel adására. A 24 névleges sík/térköz helyzetben legalább 21 műholdnak jól működőképesre /healthy/ beállítottnak kell lenni, és a navigációs jelet 0,98 valószínűséggel (éves átlagolásban) sugároznia kell.

4.1.5 *Megbízhatóság.* A megbízhatóság egy meghatározott időtartamon belül százalékban kifejezett azon idő, amikor a Szabvány Helymeghatározási Szolgáltatás /SPS/ Térbeli-jel /SIS/ Felhasználói távolságmérési hiba /URE/ a távolság hibahatár értékeken belül marad, a fedésterületen belül bármely adott ponton, az összes jó működési állapotú /healthy/ GPS műholdra. A megbízhatósági szabvány egy-éves időtartamon keresztüli méréseken és a fedés-területen belüli napi értékek átlagán alapszik. Egy adott pont átlagos megbízhatósága feltételezi azt, hogy a teljes szolgáltatási hiba ideje 18 óra lesz az adott pont felett. (3 hiba, amelyek mindegyike 6 órán keresztül tart.)

4.1.6 *Nagyobb szolgáltatási hiba.* Egy nagyobb szolgáltatási hiba úgy került meghatározásra, hogy az egy idő intervallumon keresztül fennálló állapot, amely során jó működőképességű /healthy/ GPS műholdak távolság-meghatározási jel hibája (az atmoszférikus és vevő hibákat kizárva) meghaladja a távolságmérési hibahatár értéket. Ahogy az a 3. Fejezet 3.7.3.1.1.3a) pontjában meghatározásra került, a távolságmérési hibahatár érték a következőkből a nagyobbik érték:

a) 30 méter; vagy
b) a Felhasználói Távolságmérési Pontosság /URA/ 4,42-szorosa , a 150 métert nem meghaladóan.

4.1.7 *Fedésterület.* A Szabvány Helymeghatározási Szolgáltatás /SPS/ az a földi fedésterületet támasztja alá, ami a föld felszínétől 3 000 kilométeres magasságig terjed.

4.2 GLONASS

Megjegyzés. – A GLONASS-ra vonatkozó kiegészítő tájékoztatásokat az Orosz Államszövetség Védelmi Minisztériumának Tudományos Koordinációs Téjékoztatásügyi Központja, Moszkva által kiadott GLONASS Interfész Vezérlési Dokumentumá-ban *lehet megtalálni.*

4.2.1 *Műhold kiválasztás.* A teljesítmény szabvány meghatározások arra az alapfeltételre alapozottak, hogy a szabvány pontossági csatornájú (CSA) vevő azt a műholdat fogja kiválasztani, amely minden egyes 5 percben a minimális helyzet-pontosság gyengülésen /PDOP/ alapszik, vagy bármikor azt a helyzet-megoldásban használt műholdat, amely beáll a maszk-szög alá.

4.2.2 *Pontosság.* A pontosságot a fedésterület, a rendelkezésre állási és a megbízhatósági szabványok és egy, a föld bármely pontjára mért 24 órás időtartam szabja meg.

4.2.3 *Idő átviteli pontosság.* Az idő átviteli pontosságot a fedésterület, a rendelkezésre állási és a megbízhatósági szabványok és egy, a föld bármely pontjára mért 24 órás időtartam szabja meg. Ez a GLONASS CSA vevő idejére van alapozva, ahogy az a helyzet-megoldás adat kimenetének felhasználásával kiszámításra kerül. Az idő átviteli pontosság az Egyeztetett Világidőre vonatkozóan került meghatározásra, ahogy azt az Orosz Nemzeti Idő Szolgálat (UTC(SU)) fenntartja.

4.2.4 *Rendelkezésre állás.* A rendelkezésre állást a fedésterület és egy jellemző 24 órás időtartam alatti (egy 60 napos átlagolási időtartam felhasználásával meghatározott) földfelszín feletti átlagolás szabja meg.

4.2.5 *Megbízhatóság.* A megbízhatóságot a fedésterület; a szolgáltatás rendelkezésre állása; a 200 métert nem meghaladó, előre meghatározható vízszintes megbízhatósági küszöb; egy, a mintavételezési időtartamon belüli nagyobb – maximum 18 órás – szolgáltatási hibás működés; és egy, a föld felszíne feletti egy-éves időtartam napi értékekre átlagolva adja meg.

4.2.5.1 *Nagyobb szolgáltatási hiba.* A nagyobb szolgáltatási hiba úgy van meghatározva, hogy az egy eltávolodás a szabvány távolság-mérési jel jellemzőktől olyan módon, ami egy megbízhatósági, vagy rendelkezésre állási szolgáltatási hibát okozhat. A nagyobb szolgáltatási hiba úgy került meghatározásra, hogy az egy eltávolodás a szabvány távolság-mérési jel jellemzőktől a következő módok valamelyikén:

a) olyan statisztikai eltávolodás a névleges rendszer távolságmérési pontosságtól, ami a Szabvány Pontossági Csatornában /CSA/ 150 métert meghaladó pillanatnyi távolság-meghatározási hibát okoz, vagy;

b) egy CSA távolságmérési jel, navigációs közlemény szerkezeti, vagy navigációs közlemény tartalmi megsértés, ami hatással van a CSA vevők minimális távolság-meghatározási jel vételére, vagy feldolgozó-képességére.

4.2.6 *Fedésterület.* A fedésterületet négy, vagy több műhold láthatóságának valószínűsége 24 órás időtartamban átlagolva a föld felszíne felett; egy 6, vagy annál kevesebb helyzet-pontosság gyengülés /PDOP/ négy műholdtól; egy 5-fokos maszk-szög; és a huszonnégy üzemelő műholdnak a naptár szerinti meghatározású helyzetsora /konstellációja/ szabja meg.
4.2.7 *GLONASS idő.* A GLONASS idő létrehozása a GLONASS Központi Szinkronizáló idején alapszik. A Központi Szinkronizáló hidrogén /atom/ órájának napi bizonytalansága 5×10^{-14}-nél nem rosszabb. A GLONASS idő és az Egyezetett Világidő, Oroszország /UTC(SU)/ ideje közötti különbség 1 milliszekundumon belül van. A navigációs közlemény tartalmazza a GLONASS időnek az UTC(SU)-hoz viszonyított szükséges adatait 0,7 mikro-szekundumon belüli pontossággal.

4.2.7.1 *A GLONASS-M aktuális adat információinak a közös formába történő átalakítása*. A műhold navigációs közlemény tartalmazza az aktuális adat információt az NT paraméterben. Ezt a közös formába a következő képlettel lehet átalakítani:

a) Az aktuális év-számnak, a J-nek, egy négy-éves időtartamban való kiszámítása:
Ha $1 \le N_T \le 366$; $J = 1$;
Ha $367 \le N_T \le 731$; $J = 2$;
Ha $732 \le N_T \le 1096$; $J = 3$;
Ha $1097 \le N_T \le 1461$; $J = 4$.

b) Az aktuális év a közös formában a következő képlettel kerül kiszámításra:

$$Y = 1996 + 4(N_4 - 1) + (J - 1)$$

c) Az aktuális nap és hónap (dd/mm) abból a referencia táblázatból kerül kiemelésre, ami a felhasználó berendezésének ROM-jában került tárolásra. A táblázat közös kapcsolatban van az N_T paraméterrel és a közös formátum dátummal.

4.2.8 *GLONASS koordináta rendszer.* A GLONASS koordináta rendszere a PZ-90, ahogy azt *A Föld Paraméterei, 1990 (PZ-90)* leírja, amit az Orosz Államszövetség Védelmi Minisztérium Topográfiai Szolgálata, Moszkva – kiadványában ismerteti.

4.2.8.1 A PZ-90 paraméterei magukba foglalják az alapvető geodéziai állandókat, az egységes földi ellipszoid méreteit, a föld gravitációs erőterének jellemzőit és a Kraszovszkij ellipszoid (koordináta rendszer, 1942.) elemeinek az egységes földi ellipszoidra vonatkoztatott orientációját.

4.2.8.2 A meghatározás szerint, a PZ-90 koordináta rendszer egy geocentrikus Descartes-féle derékszögű koordináta rendszerű aritmetikai tér, amelynek a kiindulópontjai a föld testjének középpontjában helyezkednek el. A Z-tengely az Egyezményes Földi pólusokra irányul, hogy azt a Nemzetközi Föld Forgási Szolgálat ajánlja. Az X-tengely a föld egyenlítői síkjának és a Nemzetközi Idő Hivatal által megállapított nulla-délkör metszéspontjára irányul. Az Y-tengely tölti be a jobbra-forgás /az óramutató forgásával egyező irányú/ koordináta rendszert.

4.3 A pontosság gyengülése

A pontosság gyengülése (DOP) tényező azt fejezi ki, hogy a távolságmérési pontosságot hogyan lehet egy geometriai hatással a helyzet-pontosság csökkenéséhez mérni. Az optimális geometriát (azaz a legalacsonyabb DOP értéket) négy műholddal lehet elérni akkor, amikor három műhold a horizonton egyenlő térközökben helyezkedik el, minimális magassági szöggel és egy műhold közvetlenül a vevő felett van.

A geometriára azt lehet mondani, hogy a távolság tartomány pontosságot a pontosság gyengülési tényezővel /DOP/ „gyengíti”.

4.4 Globális Navigációs Műhold Rendszer /GNSS/ vevő

4.4.1 A vevő által okozott hibáknak kétféle következménye lehet a navigációs rendszer teljesítményére, ezek a felhasználó részére biztosított információk félbeszakítása, vagy a félrevezető kimeneti információk. Ezen esetek egyike sincs a térbeli-jel követelményekben figyelembe véve.

4.4.2 A GNSS légijármű fedélzeti elemeinek névleges hibáját a vevő-zaj, az interferencia és a többutas terjedési és troposzférikus model megmaradó hibái határozzák meg. A meghatározott vevő-zaj követelmények mind a Műhold Bázisú Kiegészítő Rendszer /SBAS/, mind a Földi Bázisú Kiegészítő Rendszer /GBAS/ légijármű fedélzeti vevőjére magukba foglalják a B-Függelék 3.7 pontjában meghatározott védő maszk alatti bármilyen interferencia hatását. A megkívánt teljesítmény olyan vevők által került kimutatásra, amelyek keskeny korrelátor térközt, vagy kód-kiegyenlítő technikát alkalmaznak.

5. Légijármű-bázisú kiegészítő rendszer (ABAS)

5.1 Az ABAS kiegészíti és/vagy összegzi a Globális Navigációs Műhold Rendszer /GNSS/ elemeitől kapott információkat a légijármű fedélzetén rendelkezésre álló információkból abból a célból, hogy a 3. Fejezet 3.7.2.4 pontjában meghatározott értékeknek megfelelő üzemeltetést biztosítsa.

5.2 Az ABAS olyan feldolgozási kapcsolásokat foglal magába, amelyek biztosítják:

a) A sértetlenség ellenőrzését a helyzet megoldásokra a redundáns információk (például: a többszörös távolság-mérések) felhasználásával. Az ellenőrző rendszerek általában két funkciót foglalnak magukba: a hiba érzékelést és a hiba kizárást. A hiba érzékelés célja az, hogy észlelje a helymeghatározási hiba jelenlétet. Az észlelés után a megfelelő hiba kizárás meghatározza és kizárja a hiba forrását (anélkül, hogy szükségszerűen az azonosítaná azt az egyedi forrást, ami a problémát okozza), és ezáltal lehetővé teszi a GNSS navigációnak a megszakítás nélküli folytatását. A sértetlenség ellenőrzésének két alapvető osztálya van: a Vevő sértetlenség önellenőrző rendszer (RAIM), ami kizárólagosan a GNSS információkat használja fel, és a Légijármű sértetlenség önellenőrző rendszer (AAIM), ami kiegészítő légijármű fedélzeti információkat használ fel (például: a légnyomásos magasságmérő, óra és inerciális navigációs rendszer (INS));

b) A helyzet megoldás folyamatossági segítése alternatív forrásokból származó információk felhasználásával, mint az Inerciális Navigációs Rendszerrel /INS/, a légnyomásos magasságmérővel és külső órával;

c) A helyzet megoldás rendelkezésre állásának segítése (a folyamatosság segítésével azonos); és

d) A pontosság segítése a meghatározott távolságok megmaradó hibáinak becslésével.

5.3 A nem-GNSS információkat a GNSS információkkal kétféle módon lehet egyesíteni:

a) A GNSS megoldási algoritmusán belül egyesítve (Egy példa: a magasságmérési adatoknak egy kiegészítő műhold mérés jellegű modellezése); és

b) Külsőleg az alap GNSS helyzet számításhoz (Egy példa: a magasságmérési adatok összehasonlítása a megegyezés szempontjából a függőleges GNSS megoldással, ahol egy jelzés /zászló/ jelenik meg akkor, ha az összehasonlítás hibás /eltérő/.).

5.4 Az egyes kapcsolatoknak speciális előnyeik és hátrányaik vannak, és lehetetlen az összes lehetséges összekapcsolás leírása az elért teljesítmény számszerű értékeivel. Ugyanez vonatkozik arra a helyzetre, amikor több GNSS elem kerül egyesítésre (például: GPS és GLONASS).

6. Műhold-bázisú kiegészítő rendszer (SBAS)

6.1 Egy SBAS három különálló elemből épül fel:

a) a földi infrastruktúrából;

b) az SBAS műholdakból; és

c) az SBAS légijármű fedélzeti vevőből.

6.1.1 A földi infrastruktúra magába foglalja azokat az ellenőrző és jelfeldolgozó állomásokat, amelyek a navigációs műholdaktól az adatokat veszik és kiszámítják a sértetlenséget, a helyesbítéseket és a távolság-meghatározási adatokat, azokat, amelyek az SBAS térbeli-jelet képezik. Az SBAS műholdak közvetítik azokat az adatokat, amelyeket a földi infrastruktúrából a műholdak részére továbbítottak, az SBAS légijármű fedélzeti vevők részére, hogy azok meghatározzák azokat a helyzet és idő információkat, amelyeket a műholdak helyzet-sora(i) és az SBAS műholdak alkalmaznak. Az SBAS légijármű fedélzeti vevők begyűjtik a távolság és helyesbítési adatokat, és ezeket használják fel a sértetlenség meghatározásához és a származtatott helyzet-pontosság növeléséhez.

6.1.2 Az SBAS földi hálózat méri a távolság-meghatározási forrás és az SBAS vevő közötti pszeudo-távolságot az ismert helyen, és önálló helyesbítéseket biztosít a távolság-meghatározási forrás efemerisz hibáknál, az óra /idő/ hibáknál és az ionoszférikus hibáknál. A troposzférikus késési modelt a felhasználó alkalmazza.

6.1.3 A távolság-meghatározási forrás efemerisz hiba és a lassú mozgási idő hiba az elsődleges alapjai a hosszútávú korrekcióknak. A távolság-meghatározási idő hiba a hosszútávú helyesbítéseknél kerül szabályozásra, és a troposzférikus hiba a gyors helyesbítés elsődleges alapja. A több távolság-meghatározási forrás közötti ionoszférikus hibák előre meghatározott ionoszférikus rács-pontoknál lévő függőleges ionoszférikus hibákként vannak összekapcsolva. Ezek a hibák az ionoszférikus helyesbítések elsődleges bázisai.

6.2 A Műhold Bázisú Kiegészítő Rendszer /SBAS/ fedésterülete és szolgáltatási területei

6.2.1 Fontos az, hogy különbséget tegyünk egy SBAS fedésterülete és szolgáltatási területe között. Egy fedésterület egy, vagy több szolgáltatási területet foglal magába, ezek mindegyike képes arra, hogy alátámassza a 3. Fejezet 3.7.3.4.2 pontjában meghatározott SBAS összes, vagy néhány funkciójára alapozott üzemeltetéseket. Ezeket a funkciókat azokat az üzemeltetésekre lehet vonatkoztatni, amelyeket alátámasztanak a következők:

a) Távolság-meghatározás: az SBAS biztosítja a távolság-meghatározási forrást más egyéb kiegészítő rendszerrel, rendszerekkel (ABAS, GBAS és másik SBAS);

b) Műhold állapot és alap differenciál helyesbítések: az SBAS útvonal, közelkörzeti és nem-precíziós megközelítési szolgáltatásokat biztosít. Különféle üzemeltetéseket (azaz Megkívánt Navigációs Teljesítmény /RPN/ típusokat) lehet alátámasztani a különböző szolgáltatási területeken;

c) Pontos differenciál helyesbítések: az SBAS Megközelítés Függőleges Vezetéssel-t /APV/ és a precíziós megközelítési szolgáltatást (azaz az APV-I.-t, APV-II.-t és a precíziós megközelítést) lehet alátámasztani különböző szolgáltatási területeken).

6.2.2 A D-1. ábra (az összes ábra a melléklet végénél került elhelyezésre) mutatja be a kezdeti fedésterületet és a körülbelüli kezdeti szolgáltatási területeket a három SBAS-re: a Széles Területű Kiegészítő Rendszer-t (WAAS), az Európai Geostacionárius Navigációs Átfedő Szolgáltatás-t (EGNOS) és a Többfunkciós Közlekedési Műhold (MTSAT) Műhold Bázisú Kiegészítő Rendszer-t (MSAS).

6.2.3 Egy SBAS pontos és megbízható szolgáltatást biztosíthat a meghatározott szolgáltatási terület(ek)en kívül is. A távolság-meghatározási, a műhold állapot és az alap differenciál helyesbítési funkciók felhasználhatóak a teljes fedésterületen belül is. Ezeknek a funkcióknak a teljesítménye technikailag elegendő lehet az útvonal, a közelkörzeti és a nem-precíziós megközelítési üzemeltetések alátámasztására, az ellenőrző és teljességi adatoknak az állandó-pályájú műhold rendszerekre és/vagy az SBAS műholdakra történő biztosításával. A sértetlenség szempontjából a veszélyeztető lehetőség az a műhold efemerisz hiba, amit az SBAS földi hálózat nem tud érzékelni, miközben az egy elfogadhatatlan hibát hoz létre a szolgáltatási területen kívül. A nem-precíziós megközelítésre meghatározott 0,3 tengeri mérföldes, vagy annál nagyobb riasztási határértékek elérése nagyon valószínűtlen.

6.2.4 Az egyes Államok felelősek azért, hogy a légtereiken belül meghatározzák az SBAS szolgáltatási területeket, és jóváhagyják az SBAS-bázisú üzemeltetéseket. Bizonyos esetekben, az Államok fel fognak állítani SBAS földi infrastruktúrát egy meglévő SBAS-hez kapcsolódóan. Ezeknek szükséges lesz az, hogy elérjék a Megközelítés Függőleges Vezetéssel /APV/-hez, vagy a precíziós megközelítéshez szükséges teljesítményt. Más esetekben az Államok egyszerűen jóváhagyhatnak szolgáltatási területeket és a rendelkezésre álló SBAS jeleket felhasználó, SBAS-alapú üzemeltetéseket. Mindkét esetben az egyes Államok felelősek annak biztosításáért, hogy az SBAS kielégíti a 3. Fejezet 3.7.2.4 pontjának követelményeit a légterükön belül, és hogy a légterükről megfelelő üzemelési állapot jelentések és NOTAM-ok kerülnek biztosításra.

6.2.5 Az SBAS-alapú üzemeltetések jóváhagyása előtt az Államnak meg kell határoznia azt, hogy a javasolt üzemeltetéseket egy, vagy több SBAS kellően alátámasztja. Ennek a meghatározásánál az SBAS-jelek felhasználásának gyakorlatára kell összpontosítani, számításba véve az SBAS földi hálózat relatív elhelyezkedését. Ez magában foglalhatja az SBAS-ek üzemeltetéséért felelős Állam(okk)al, vagy szervezet(ekk)el való együttműködést. Egy olyan légtérnél, ami viszonylag távol helyezkedik el az SBAS földi hálózattól, lecsökkenhet azoknak a látható műholdaknak a száma, amelyekre az SBAS állapot és alap helyesbítéseket biztosít. Mivel az SBAS vevők képesek arra, hogy egyidejűleg két SBAS adatait használják fel, és az önálló hiba észlelés és kizárás alkalmazására, amikor az szükséges, a rendelkezésre állás még így is elegendő lehet az üzemeltetések jóváhagyásához.

6.2.6 Az államtól elvárt az, hogy mielőtt az SBAS jelekre alapozott eljárásokat közzétenné, egy állapot ellenőrzést és egy NOTAM rendszert biztosítson. Egy rendszer elem hibájának a szolgáltatásra gyakorolt hatása meghatározásához matematikai szolgáltatási teljesítmény modellt kell felhasználni. Az Állam a modellt, vagy az SBAS üzemeltetőjétől szerezheti be, vagy kifejlesztheti saját modelljét. Az alap rendszer elemeinek pillanatnyi és előrejelzett állapot adatai és annak a helynek az adatai felhasználásával, ahova az Állam az üzemeltetéseket jóváhagyta, a modell képes lesz azonosítani azt a légteret és azokat a repülőtereket, ahol szolgáltatási kimaradások várhatóak, és ezt lehet felhasználni a NOTAM-ok létrehozásához. A modellhez szükséges rendszer alkotóelem állapot adatokat (pillanatnyi és előrejelzett), vagy az SBAS szolgáltatás biztosítóval kötött kétoldalú szerződésen keresztül lehet beszerezni, vagy pedig az adatok egy valós idejű 'sugárzási' kapcsolatán keresztül, ha az SBAS szolgáltatást biztosító az adatok biztosításának ezt az útját választja.

6.2.7 A résztvevő Államok, vagy körzetek az ICAO-n keresztül fognak koordinálni annak megvalósításáért, hogy az SBAS megszakítás nélküli globális fedést biztosítson, számításba véve azt, hogy az a légijármű, amelyik a jel felhasználásra fel van szerelve, üzemeltetési korlátozásokat szenvedhet el abban az esetben, ha egy Állam, vagy egy körzet nem engedélyezi egy, vagy több SBAS jelnek a légterében történő felhasználását. Az ilyen esetben lehet, hogy a légijármű vezetőjének teljes egészében le kell választania a Globális Navigácós Műhold Rendszert /GNSS/, mivel a légijármű berendezései nem teszik lehetővé az összes SBAS, vagy egy meghatározott SBAS leválasztását.

6.2.8 Mivel az SBAS geostacionárius pályájú műhold fedésterülete (lábnyom) egymást átfedi, „interfész kérdések" lesznek az SBAS-ek között. Minimumként az SBAS légijármű fedélzeti vevőknek képesnek kell lenniük bármilyen SBAS fedésterületén belül üzemelni. Egy SBAS szolgáltatást biztosító részére lehetséges az, hogy olyan geostacionárius pályájú műholdat ellenőrizzen, és sértetlenségi és helyesbítési adatokat küldjön arról, amelyek egy másik SBAS szolgáltatás biztosítóhoz tartoznak. Ez növeli a rendelkezésre állást, a távolság-meghatározási források hozzáadásával. Ehhez a növekedéshez nem szükséges semmilyen 'összekapcsolás' az SBS rendszerek között, és ezt az összes SBAS szolgáltatás biztosítónak teljesítenie kell.

6.2.9 Az integrálás egy másik szintjét lehet megvalósítani az SBAS hálózatok közötti egyedül álló összekapcsolással (azaz önálló műhold összeköttetéssel). Ebben az esetben az SBAS-ek vagy elsődleges műhold mérési adatokat tudnak cserélni egy, vagy több referencia állomástól, vagy feldolgozott adatokat (helyesbítési, vagy sértetlenségi adatokat) a törzs állomásaitól. Ezt az információt fel lehet használni a rendszer hiba-tűrésének és pontosságának növelésére, az adatok középérték meghatározásán keresztül, vagy a teljesség növelésére egy kereszt-ellenőrzési mechanizmuson keresztül.
A rendelkezésre állást ugyancsak növelni lehet a szolgáltatási területen belül, és a műszaki teljesítmény ki fogja elégíteni a GNSS Szabványok és Ajánlott Gyakorlatok előírásait a teljes fedésterületen belül (azaz a műholdak efemerisz ellenőrzése javulni fog). Végül, az SBAS ellenőrző és állapot adatokat lehet cserélni a rendszer karbantartásának növelésére.

6.3 Sértetlenség

6.3.1 A sértetlenség előírásai összetettek, mivel a jellemző tulajdonságok egy része az SBAS földi hálózaton belül kerül meghatározásra és a térbeli-jelbe továbbításra, míg a többi jellemző tulajdonság a légijármű fedélzetén lévő SBAS berendezésen belül kerül meghatározásra. A műhold működési állapotára és az alap helyesbítési funkciókra vonatkozó, az efemerisz és óra /idő/ helyesbítésekre vonatkozó hiba bizonytalanságot az SBAS földi hálózat határozza meg. Ezt a bizonytalanságot egy nulla-átlagú szórásnégyzet modellezi, a normális eloszlást, ami a felhasználói differenciál távolság-mérési hibát (UDRE) írja le az egyes távolság-meghatározási forrásokra, a gyors és a hosszútávú helyesbítések alkalmazása után, valamint az atmoszférikus hatások és vevő hibák kizárásával.

6.3.2 A pontos differenciál funkcióhoz az ionoszférikus helyesbítés egy hiba bizonytalansága is meghatározásra kerül. Ezt a bizonytalanságot egy nulla átlagú szórásnégyzet modellezi, a normális eloszlást, ami az L1, a maradék Felhasználói Ionoszférikus Távolság Hibát (UIRE) írja le az egyes távolság-meghatározási forrásokra, az ionoszférikus helyesbítések alkalmazása után. Ez a szórásnégyzet egy, a Sugárzási Hálózati Ionoszférikus Függőleges Hiba (GIVE) felhasználásával egy ionoszférikus modellből kerül meghatározásra.

6.3.3 Van egy véges valószínűség arra, hogy egy SBAS vevő nem fog venni egy SBAS közleményt. Abból a célból, hogy az ilyen esetben a navigáció folytatódjon, az SBAS teljesítőképesség csökkenési paramétereket sugároz a térbeli-jelben. Ezek a paraméterek több matematikai modellben kerülnek felhasználásra a kiegészítő maradék hibák leírására mindkét, azokhoz az alap és a pontos differenciál helyesbítésekhez, amelyeket az elöregedett, de aktív adatok hoznak létre. A modellek a Felhasználói Differenciál Távolságmérési Hiba /UDRE/ és a Felhasználói Ionoszférikus Távolság Hiba (UIRE) szórásnégyzetének módosítására használatosak, ahogy az megfelelő.

6.3.4 A fentiekben leírt egyedi hiba bizonytalanságokat használja fel a vevő arra, hogy kiszámítsa a navigációs megoldás egy hiba modelljét. Ezt úgy végzi el, hogy a pszeudo-távolság hiba modelleket kivetíti a helyzet területére. A Vízszintes Védelmi Szint (HPL) egy korlátozást biztosít a vízszintes helyzet hibára a sértetlenségi követelményekből levezetett valószínűséggel. Hasonlóképpen, a Függőleges Védelmi Szint (VPL) biztosítja a függőleges helyzet korlátozást. Ha a kiszámított HPL egy meghatározott üzemeltetésre meghaladja a Vízszintes Riasztási Határértéket (HAL), akkor az SBAS sértetlensége nem elegendő annak az üzemeltetésnek az alátámasztására. Ugyanez igaz a precíziós megközelítési és a Megközelítés Fügőleges Vezetéssel /APV/ üzemeltetésekre is, ha a VPL meghaladja a Függőleges Riasztási Határértéket (VAL).

6.3.5 Egy SBAS szolgáltatás biztosító részére az egyik legnagyobb kihívást jelentő feladat a Felhasználói Differenciál Távolságmérési Hiba /UDRE/ és a Hálózati Ionoszférikus Függőleges Hiba /GIVE/ szórásnégyzeteinek meghatározása úgy, hogy a védelmi szint sértetlenségi követelmények kielégítésre kerüljenek anélkül, hogy befolyása lenne a rendelkezésre állásra.
Egy egyedi SBAS teljesítménye függ a hálózat konfigurációjától, a földrajzi kiterjedéstől és a sűrűségtől, a felhasznált mérések típusától és minőségétől, valamint az adatok feldolgozásához használt algoritmusoktól. A modell szórásnégyzet meghatározásának általános módszere a 13. Részben került leírásra.

6.3.6 *Maradék óra és efemerisz hiba* (σ_{UDRE}). A megmaradó óra hiba jól leírható egy nulla átlagú normális eloszlással, mivel több vevő van, ami ebben a hibában részt vesz. A megmaradó efemerisz hiba a felhasználó helyzetétől függő. A pontos differenciál funkció érdekében az SBAS szolgáltatás biztosító biztosítani fogja azt, hogy a megmaradó hiba az összes felhasználó részére egy meghatározott szolgáltatási területen belül a σ_{UDRE}-ben tükrözésre kerüljön. Az alap differenciál funkcióra a megmaradó efemerisz hibát, mint figyelmen kívül hagyhatót, lehet kiértékelni és meghatározni.

6.3.7 *Függőleges ionoszférikus hiba* (σ_{GIVE}). A megmaradók ionoszférikus hibát jól jeleníti mg egy nulla átlagú normális eloszlás, mivel több vevő van, ami az ionoszférikus becslésben részt vesz. A hibák a mérési zajból, az ionoszférikus modellből és az ionoszféra térbeli dekorrelációjából erednek.

Az ionoszférikus hiba által okozott helyzet hibát magának az ionoszférának a pozitív korrelációja csillapítja. Ezenkívül a megmaradó ionoszférikus hiba eloszlásnak levágott végei vannak, azaz az ionoszféra nem tud létrehozni negatív késést és így egy maximális késése van.

6.3.8 *Légijármű fedélzeti alkotó-elem hibák.* Az összetett többutas szóródás és a vevő hozzájárulás úgy kerül korlátozásra, ahogy az a 13. Részben van leírva. Ezt a hibát a többutas szóródásra és a vevő hozzájárulására lehet felosztani úgy, ahogy az a B-Függelék 3.6.5.5.1 pontban meghatározásra került, és a többutas szóródás egy szabvány modelljét lehet felhasználni. A vevő hozzájárulást a pontossági követelményekből (B-Függelék 3.5.8.2 és 3.5.8.4.1 pont) lehet venni és extrapolálni a jellemző jel körülményekre. Kifejezetten a légijárműnél el lehet fogadni azt, hogy $\sigma^2_{air} = \sigma^2_{vevő} + \sigma^2_{többutas}$ hibája van, ahol elfogadott az, hogy a $\sigma_{vevő}$-t az az RMS_{pr_air} határozza meg, ami a Földi Kiegészítő Rendszer /GBAS/ Légijármű-fedélzeti Pontossági Jelölés A-berendezésre előírt, és a $\sigma t_{öbbutas}$-t a B-Függelék 3.6.5.5.1 pontja határozza meg. A légijárműnek a többutas szóródásban való hozzájárulása magában foglalja a magától a légijárműtől eredő reflexiós hatásokat. A más tárgyaktól eredő reflexió által eredményezett többutas hibák nem kerültek számításba. Ha a tapasztalat azt mutatja, hogy ezek a hibák nem elhanyagolhatóak, akkor azokat üzemeltetési szempontból számításba kell venni.

6.3.9 *Troposzférikus hiba.* A vevőnek fel kell használni egy modellt a troposzférikus hatások helyesbítéséhez. A modell maradék hibáját a maximális torzítás, valamint a B-Függelék 3.5.8.4.2 és 3.5.8.4.3 pontjában meghatározott szórásnégyzet eltérés szűkíti. Ennek az átlagnak a hatásait a földi al-rendszernek kell számításba venni. A légijármű fedélzeti felhasználók egy meghatározott modellt alkalmaznak a maradék troposzférikus hibára (σ_{tropo}).

6.4 Rádiófrekvenciás /RF/ jellemzők

6.4.1 *Műhold Bázisú Kiegészítő Rendszer /SBAS/ ál-véletlen zaj (PRN) kódok.* Az RTCA/DO-229C ”A”- Függeléke két módszert biztosít az SBAS PRN kód generálására.

6.4.2 *Műhold Bázisú Kiegészítő Rendszer /SBAS/ hálózat idő.* Az SBAS hálózat idő egy, az SBAS által fenntartott idő referencia a helyesbítések meghatározása céljára. Amikor a helyesbítések alkalmazásra kerülnek, akkor a felhasználó beállítási ideje az SBAS hálózat idejére vonatkozó, és nem pedig a műhold helyzet-sor rendszer idejére. Ha helyesbítések nem kerülnek alkalmazásra, akkor a helyzet megoldás egy összetett, a műhold helyzet-sor rendszer/műhold bázisú kiegészítő rendszer hálózat idejére kerül vonatkoztatásra a felhasznált műholdaktól függően, és a létrejövő pontosságot a közöttük lévő különbség fogja befolyásolni.

6.4.3 *A Műhold Bázisú Kiegészítő Rendszer /SBAS/ konvolúciós kódolása.* Az SBAS közlemények konvolúciós kódolására és dekódolására vonatkozó tájékoztatásokat az RTCA/DO-229C ”A”-Függelékében lehet megtalálni.

6.4.4 *Közlemény időzítés.* A felhasználók konvolúciós dekódere egy rögzített késleltetést fog bevezetni, ami az ő megfelelő algoritmusuktól függ (általában 5 befogás hossz, vagy 35 bit), amelyet ki kell egyenlíteniük a vett jelből az SBAS hálózati idő (SNT) meghatározásához.

6.5 Műhold Bázisú Kiegészítő Rendszer /SBAS/ adat jellemzők

6.5.1 *SBAS közlemények.* A korlátozott sávszélesség miatt az SBAS adatok olyan közleményekbe vannak kódolva, amelyek célja az, hogy a minimálisra csökkentsék a szükséges adat átmenetet. Az RTCA/DO-229C ”A”- Függeléke adja meg az SBAS közlemények részletes előírásait.

6.5.2 *Adatsugárzási időközök.* Az SBAS közlemények közötti maximális sugárzási időközök a ”B”-Függelék B-54. táblázatában kerültek meghatározásra. Ezek az időközök olyanok, hogy az SBAS szolgáltatási területére belépő felhasználó képes egy helyesbített helyzet információ kimenetet kapni, az SBAS által biztosított sértetlenségi információval együtt, elfogadható időn belül. Az útvonal, a közelkörzeti és a nem-precíziós megközelítési /NPA/ üzemeltetésekhez szükséges adatok 2 percen belül vételre fognak kerülni, míg a precíziós megközelítési üzemeltetésekre ez maximum 5 percet fog jelenteni. A sugárzások közötti maximális időközök nem garantálják a pontossági teljesítmény egy meghatározott szintjét, ahogy az a 3. Fejezet 3.7.2.4-1. táblázatában meghatározásra került. Abból a célból, hogy egy adott pontossági teljesítmény biztosítva legyen, az egyes szolgáltatás biztosítók el fognak fogadni egy sugárzási időköz rendszert az olyan különféle paramétereket figyelembe véve, mint például a konstelláció típusa (azaz GPS Szelektív elérhetőséggel /SA/, GPS SA nélkül) vagy az ionoszférikus aktivitás.

6.5.2.1 A gyors helyesbítésekre a B-54. táblázat lehetővé teszi azt, hogy a maximális sugárzási időköz 60 másodperc legyen. A B-56. táblázat megadja a különféle adat közleményekre az adat idő túllépési időközöket a B-57. táblázatra hivatkozva, ami a gyors helyesbítések idő túllépési időközét a gyors helyesbítések teljesítőképesség csökkenési jelzése (ai_i) függvényeként mutatja be. Azonban ha a szolgáltatás biztosító a gyors helyesbítés sugárzási időközeként a 60 másodpercet választja és az ai_i 15 volt, akkor a felhasználó amiatt, hogy az adat idő túllépés megelőzi a következő sugárzást, nem kapná meg a gyors helyesbítéseket a Nem-precíziós megközelítési (NPA) és a Függőleges útirány vezetéses megközelítés – I. (APV-I.) minden egyes percének 42 másodpercére és az APV-II., valamint a Precíziós megközelítés (PA) minden egyes percének 48 másodpercére.

Abból a célból, hogy biztosítva legyen az, hogy a légijármű fedélzeti elemei érvényes gyors helyesbítéseket ilyen megszakítások nélkül dolgozzanak fel, a gyors helyesbítésekre a maximális sugárzási időközt olyan értékre kell beállítani, ami az NPA és az APV-I. gyors helyesbítési idő túllépésének az egyharmada, és az APV-II. és a PA gyors helyesbítési idő túllépésének a fele, ahogy azt az ai_i meghatározza.

Megjegyzés. – A maximális gyors helyesbítés sugárzási időközöket az egyes ai_i-kre az RTCA/DO-229C A-8. táblázatában lehet megtalálni.

6.5.3 *Idő-a-riasztásig.* A D-2. ábra adja meg a 3. Fejezet 3.7.2.4-1. táblázatában meghatározott teljes idő-a-riasztásig kiosztás magyarázó anyagát. Az idő-a-riasztásig követelmények a B-Függelék 3.5.7.3.1, 3.5.7.4.1 és 3.5.7.5.1 pontjában leírtak (a GNSS műhold állapotok, az alap differenciál helyesbítések és a pontos differenciál helyesbítési funkcióknak – külön-külön – megfelelő), a D-2. ábrában bemutatottak pedig magukba foglalják mind a földi, mind az űrbeli elosztást.

6.5.4 *Troposzférikus funkció.* Mivel a troposzférikus törés egy helyi elhajlási jelenség, ezért a felhasználók fogják kiszámítani a saját troposzférikus késési helyesbítéseiket. A precíziós megközelítésre egy troposzférikus késési becslés került leírásra az RTCA/DO-229C-ben, ennek ellenére más modellt is fel lehet használni.

6.5.5 *Többutas szóródási megfontolások.* Az SBAS hely-meghatározási hibáinak az egyik legnagyobb hozzájárulója a többutas szóródás, és mind a földi, mind a légijármű fedélzeti elemekre hatással van. Az SBAS földi elemeinél hangsúlyt kell fektetni a többutas szóródás hatásának lecsökkentésére, vagy csillapítására, amennyire az csak lehetséges, úgy, hogy a térbeli-jel bizonytalansága kicsi legyen. Több csillapítási technika került tanulmányozásra mind az elméleti, mind a tapasztalati távlatokban. A legjobb megközelítés az SBAS referencia állomásoknak a minimális többutas szóródási hibákkal való megválasztására:

a) Annak biztosítása, hogy többutas szóródási csökkentő jellemzőjű antenna kerüljön kiválasztásra;

b) A földi síkfelület technika mérlegelése;

c) Annak biztosítása, hogy az antenna egy alacsony többutas terjedési hatású helyszínen kerüljön elhelyezésre; és

d) Többutas szóródás csökkentő vevő hardver és jelfeldolgozó technika alkalmazása.

6.5.6 *GLONASS adat kibocsátás.* Mivel a meglévő GLONASS felépítés nem biztosít egy egyértelműen meghatározott azonosítót az efemerisz és az óra adatok sorozatának azonosítására, ezért az SBAS egy különleges mechanizmust fog felhasználni ahhoz, hogy a sugárzott helyesbítések alkalmazásában minden bizonytalanság elkerülésre kerüljön. Ez a mechanizmus a D-3. ábrában kerül elmagyarázásra. A várakozási idő és az érvényességi időtartam meghatározását a hozzá kapcsolódó kódolási követelményekkel együtt a
”B”- Függelék 3.5.4 részében lehet megtalálni. A felhasználó a vett hosszú-távú helyesbítéseket csak akkor alkalmazhatja, ha a fedélzeten felhasznált GLONASS efemerisz és óra adatállomány az érvényességi időtartamon belül kerül vételre.

6.6 Műhold Bázisú Kiegészítő Rendszer /SBAS/ Végső Megközelítési Szakasz (FAS) adatblokk

6.6.1 A Műhold Bázisú Kiegészítő Rendszer /SBAS/ Végső Megközelítési Szakasz (FAS) adatblokk egy meghatározott megközelítési eljárásra a D-1. táblázatban kerül bemutatásra. Ez ugyanolyan, mint a Földi Bázisú Kiegészítő Rendszer /GBAS/ Végső Megközelítési Szakasz /FAS/ adatblokkja, amely a ”B”- Függelék 3.6.4.5 pontjában került meghatározásra azzal a kivétellel, hogy az SBAS FAS adatblokk magába foglalja még a megközelítési eljárásra használatos Oldalirányú /Vízszintes/ Riasztási Határértéket /HAL/ és a Függőleges Riasztási Határértéket /VAL/ úgy, ahogy az a 6.3.4 pontban leírásra került.

6.6.2 A Műhold Bázisú Kiegészítő Rendszer /SBAS/ Végső Megközelítési Szakasz (FAS) adatblokkja és néhány Földi Bázisú Kiegészítő Rendszer /GBAS/ megközelítés egy közös fedélzeti adatblokkban van tárolva, mely támogatja mind a Műhold Bázisú Kiegészítő Rendszert /SBAS/, mind a Földi Bázisú Kiegészítő Rendszert /GBAS/. Ezen az adatbázison belül minden egyes megközelítéshez egyedi csatorna kiosztásnak kell tartoznia és ezt a polgári hatóságoknak kell koordinálnia. Az Államok a felelősek az adatbázisba kerülő Végső Megközelítési Szakasz (FAS) adat biztosításáért. Egy egyedi megközelítési eljárás Végső Megközelítési Szakasz (FAS) adatblokkja a ”B”- Függelék 3.6.4.5.1 pontja és a B-66. Táblázat alatt van ismertetve.

D-1. Táblázat: Műhold Bázisú Kiegészítő Rendszer (SBAS)

Végső Megközelítési Szakasz (FAS) adatblokk

Adattartalom	Felhasznált bitek száma	Érték tartomány	Felbontás
Üzemeltetés típusa	4	0-tól 15-ig	1
SBAS szolgáltatás biztosító azonosító (ID)	4	1-től 15-ig	1
Repülőtér azonosító (ID)	32	-	-
Futópálya azonosító száma (1. Megjegyzés)	6	0-tól 36-ig	1
Futópálya azonosító betűjele	2	-	-
Megközelítési teljesítmény kijelölő	3	0-tól 7-ig	1
Útvonal jelzés	5	-	-
Referencia pálya adat kiválasztó	8	0-tól 48-ig	1
Referencia pálya azonosító	32	-	-
Leszállási küszöb-pont / Látszólagos küszöb-pont (LTP/FTP) földrajzi szélesség	32	±90,0°	0,0005 arc szekundum

Adattartalom	Felhasznált bitek száma	Érték tartomány	Felbontás
Leszállási küszöb-pont / Látszólagos küszöb-pont (LTP/FTP) földrajzi hosszúság	32	±180,0º	0,0005 arc szekundum
Leszállási küszöb-pont / Látszólagos küszöb-pont (LTP/FTP) magasság	16	-512,0-tól 6041,5m-ig	0,1m
Repülési pálya irány-pont ∆FPAP földrajzi szélesség	24	±1,0º	0,0005 arc szekundum
Repülési pálya irány-pont ∆FPAP földrajzi hosszúság	24	±1,0º	0,0005 arc szekundum
Megközelítési küszöb keresztezési magasság (TCH) (2. Megjegyzés)	15	0-tól 1638,35m-ig (0-tól 3276,7 láb)	0,05m (0,1 láb)
Megközelítési küszöb keresztezési magasság (TCH) mértékegység kiválasztó	1	-	-
Siklópályaszög (GPA)	16	0-tól 90º-ig	0,01º
Útirány szélesség a küszöbnél (1. Megjegyzés)	8	80,0-tól 143,75m-ig	0,25m
∆Hosszúság (távolság) eltolás	8	0-tól 2032m-ig	8m
Oldalirányú Vízszintes riasztási határérték (HAL)	8	0-tól 50,8m-ig	0,2m
Függőleges riasztási határérték (VAL) (3. Megjegyzés)	8	0-tól 50,8m-ig	0,2m
Végső megközelítés szakasz Ciklikus Redundancia Ellenőrzés (CRC)	32	-	-

1. Megjegyzés. – Amikor a futópálya száma 00-ra van állítva, akkor az útirány szélesség mező figyelmen kívül van hagyva és az útirány szélessége 38 m.

2. Megjegyzés. – Az információ megadható méterben, vagy lábban, amit a megközelítési küszöb keresztezési magasság (TCH) mértékegység jelez.

3. Megjegyzés. – A 0-s értékű Függőleges Riasztási Határérték (VAL) azt jelzi, hogy függőleges eltéréseket nem használnak (azaz megközelítés csak oldalirányú útirány-vezetéssel)

7. Földi Bázisú Kiegészítő Rendszer (GBAS) és Földi Bázisú Regionális Kiegészítő Rendszer (GRAS)

Megjegyzés. – Ebben a részben, kivéve ott, ahol külön meg van említve, a Megközelítés Függőleges Vezetéssel (APV) elnevezés APV-I-t és APV-II-t jelent.

7.1 Rendszer leírás

7.1.1 A GBAS földi és légijármű fedélzeti alkotó-elemeket foglal magába. Egy GBAS földi al-rendszer (földi állomás) tipikusan a következőkből épül fel: egy egyedül álló VHF adat sugárzó (VDB) adó a sugárzó antennával – ezt sugárzó állomásnak jelölik, - valamint több referencia vevő. Egy GBAS földi al-rendszer állhat több VDB adóból és antennából, melyek megosztoznak egy közös GBAS azonosítón (GBAS ID) és frekvencián ugyanúgy, mint a kisugárzandó adaton.
Egy GBAS földi al-rendszer (földi állomás) támogatni tudja a 'fedésterületén belül' lévő összes légijármű fedélzeti al-rendszert – ellátva a légijárműveket megközelítési adatokkal és a GNSS műholdak helyesbítési és sértetlenségi információival.
Az összes olyan nemzetközi repülőgép, mely alátámasztja a Megközelítés Függőleges Vezetéssel-t (APV), köteles kezelni a fedélzeti adatbázison belül a megközelítési adatot.
A 4. Típusú üzenetet kell kisugározni, ha a földi al-rendszer támogatja az 1. Kategóriájú precíziós megközelítéseket. A 4. Típusú üzenetet akkor is ki kell sugározni, amikor a földi al-rendszer APV megközelítéseket támogat, miközben a megközelítési adatra a fedélzeti adatbázisban szereplő Államnak erre nincs szüksége.

Megjegyzés. – A GBAS al-rendszerek közötti teljesítmény követelmények kiosztását és a kiosztás módszertanát az RTCA/DO-245 Minimális Repülési Teljesítmény Szabványok a Globális Helymeghatározó Rendszerre/Helyi Körzeti Kiegészítő Rendszerre (GPS/LAAS)-ban lehet megtalálni. A Földi Bázisú Regionális Kiegészítő Rendszer (GRAS) fedélzeti berendezés számára a Minimális Működési Teljesítmény Szabványok kidolgozás alatt van, ezt az RTCA végzi.

7.1.2 A GBAS földi al-rendszerek két szolgáltatást biztosítanak: a precíziós megközelítési szolgáltatást és a GBAS hely-meghatározási szolgáltatást. A precíziós megközelítési szolgáltatás 'eltérési' repülési pálya-vezetést biztosít a végső megközelítési szakaszokra, míg a GBAS hely-meghatározási szolgáltatás vízszintes helyzet információkat biztosít az RNAV üzemeltetéseknek a közelkörzeti területen belüli alátámasztásra. A két szolgáltatás között a másik alapvető megkülönböztetés az eltérő teljesítmény követelmények, összekapcsolódva a támogatott egyedi eljárásokkal (lásd 3.7.2.4-1. Táblázatot), beleértve az eltérő sértetlenségi /integritás/ követelményeket, amelyek a 7.5.1 pontban kerülnek tárgyalásra.

7.1.3 A GBAS földi al-rendszerek elsődleges megkülönböztető jellemzője az, hogy sugározzák-e a kiegészítő efemerisz-hiba helyzet határ paramétereket. Ez a jellemző a hely-meghatározási szolgáltatáshoz szükséges, de választható a megközelítési szolgáltatásokhoz is. Amikor a kiegészítő efemerisz-hiba helyzet határok nem kerülnek sugárzásra, akkor a földi al-rendszer felelős a távolság-mérési források efemerisz adatai sértetlenségének biztosításáért anélkül, hogy a légijárművek az efemerisz határokat számítanák és alkalmaznák, ahogy az a 7.5.9 pontban tárgyalásra kerül.

7.1.4 Ennek megfelelően a GNSS szabványoknak eleget tevő GBAS földi al-rendszereknek többféle lehetséges konfigurációja van:

a) Az a konfiguráció, amely csak az I. kategóriájú megközelítéseket támasztja alá;

b) Az a konfiguráció, amely alátámasztja az I. Kategóriájú precíziós megközelítéseket és az APV-t, és még sugározza a kiegészítő efemerisz-hiba helyzet határ paramétereket is; és

c) A konfiguráció, amely alátámasztja az I. Kategóriájú precíziós megközelítést, az APV-t és a GBAS hely-meghatározási szolgáltatást, miközben sugározza a b) pontban hivatkozott efemerisz-hiba helyzet határ paramétereket is.

d) A konfiguráció, amely alátámasztja az APV és GBAS hely-meghatározási szolgáltatást és a Földi Bázisú Regionális Kiegészítő Rendszeren (GRAS) belül használják.

7.1.5 A felhasználó szempontjából egy Földi Bázisú Regionális Kiegészítő Rendszer (GRAS) földi al-rendszer (földi állomás) egy, vagy több GRAS földi al-rendszerből áll (ahogy a 7.1.1-től a 7.1.4 pontig ismertetve van), mindegyik egy egyedi GBAS azonosítóval rendelkezik és alátámasztják a hely-meghatározási szolgáltatást és az APV-t, ahol szükséges. Több GBAS sugárzó állomás használatával és a 101. Típusú üzenet kisugárzásával a GRAS alkalmassá válik, hogy támogassa az útvonal eljárásokat a GBAS hely-meghatározási szolgáltatáson keresztül, miközben támogatja a körzeti, az indulási és APV eljárásokat is egy nagyobb lefedési területen, mint azt tipikusan a GBAS teszi. Néhány GRAS alkalmazásnál a 101. Típusú üzenetben kisugárzott helyesbítések a lefedési területen elosztott referencia vevők hálózatából megszerzett adat felhasználásával számíthatók ki. Ez lehetővé teszi a mérési hibák és a vevő hibák észlelését és csökkentését.

7.1.6 Egy GBAS földi al-rendszer (földi állomás) minden sugárzó állomása azonos adatot sugároz ki azonos frekvencián, ugyanazzal a GBAS azonosítóval. A repülőgép fedélzeti vevőjének nem szükséges és nem is tud különbséget tenni a GBAS földi al-rendszer különböző sugárzó állomásaitól érkező üzenetei között. Amikor két ilyen sugárzó állomás lefedési területén belül van, a vevő kétszer kapja meg és dolgozza fel ugyanazt az üzenetet eltérő idő-osztásos többszörös hozzáférésű (TDMA) időrésben.

7.1.7 Az RTCA/DO-253A szabványú GBAS földi és a fedélzeti egységek közötti működőképességet a ”B”- Függelék 3.6.8.1 pont tartalmazza. Az RTCA/DO-253A előírásnak megfelelő GBAS vevők nem lesznek kompatibilisek a 101. Típusú üzeneteket sugárzó GRAS földi al-rendszerekkel. Ugyanakkor az RTCA GRAS MOPS-nak megfelelő GRAS és GBAS vevők kompatibilisek a GBAS földi al-rendszerekkel. A Szabványok és Ajánlott Gyakorlatok-nak megfelelő GBAS vevők lehet, hogy nem tudják dekódolni helyesen a GBAS földi al-rendszerektől az APV-hez kiadott Végső Megközelítési Szakasz (FAS) adatot.
Ezek a vevők a Végső Megközelítési Szakasz Oldalirányú Riasztási Határérték (FASLAL) és a Végső Megközelítési Szakasz Függőleges Riasztási Határérték (FASVAL) adatot úgy kezelik, mintha 1. Kategóriás precíziós megközelítésű vezetés lenne. A biztonságos üzemeltetés biztosítása érdekében megfelelő üzemeltetési szigorításokat kell alkalmazni.

7.1.8 A GBAS VDB adat sugárzás vagy vízszintes, vagy elliptikus polarizációval (GBAS/H, vagy GBAS/E) történik. Ez lehetővé teszi a szolgáltatás biztosítóknak azt, hogy hozzá igazítsák a sugárzást az üzemeltetési követelményeikhez és a felhasználói közösséghez.

7.1.9 A légijárművek többsége vízszintesen polarizált VDB adat sugárzási vevő antennával lesz felszerelve, ami képes lesz arra, hogy a VDB adat sugárzást mind a GBAS/H, mind a GBAS/E berendezésektől vegyék. A légijárművek egy része függőlegesen polarizált antennával lesz felszerelve, felszerelési korlátozások, vagy gazdaságossági megfontolások miatt. Ezek a légijárművek nem egyeztethetők össze a GBAS/H berendezéssel, és ennek megfelelően olyan GBAS-alapú üzemeltetésekre korlátozottak, amelyeket GBAS/E támaszt alá.

7.1.10 A GBAS szolgáltatás biztosítóknak közzé kell tenniük a földi állomások típusát (GBAS/H, vagy GBAS/E) az egyes GBAS állomásokra a Légiforgalmi Tájékoztató Kiadványban (AIP). Azoknak a légijármű üzemeltetőknek, akik függőlegesen polarizált vevő antennákat használnak, figyelembe kell venni ezt az információt, amikor a repülési üzemeltetéseiket kezelik, beleértve a repülés tervezési és esetleges eljárásokat is.

7.2 Rádiófrekvenciás /RF/ jellemzők

7.2.1 *Frekvencia és időrés tervezés*

7.2.1.1 *Teljesítmény tényezők*

7.2.1.1.1 Egy tervezett GBAS állomás és meglévő VOR, vagy GBAS telepített berendezések közötti földrajzi elkülönítéseknél a következő tényezőket kell számításba venni:

a) A tervezett GBAS fedésterületének kiterjedését, a minimális térerősségét és a kisugárzott teljesítményét (ERP) a GBAS helymeghatározási szolgáltatást is beleértve, ha ilyet biztosítanak. A fedésterületre és a térerősségre vonatkozó minimális követelményeket a 3. Fejezet 3.7.3.5.3 és 3.7.3.5.4.4 pontjában lehet megtalálni külön-külön. A kisugárzott teljesítményt /ERP/ ezekből a követelményekből lehet meghatározni;

b) A környezetben lévő VOR és GBAS állomások fedésterületének kiterjedését, minimális térerősségét és kisugárzott teljesítményét /ERP/, a GBAS helymeghatározási szolgáltatást is beleértve, ha ilyet biztosítanak. A VOR-ra vonatkozó fedésterület és térerősség előírásokat a 3. fejezet 3.3 pontjában lehet megtalálni; és a megfelelő útmutató anyagot a "C"- Melléklet adja meg;

c) A VHF adat sugárzás /VDB/ vevők teljesítményét, beleértve a közös-csatorna és a szomszédos csatorna csillapítást és az FM sugárzás jeleitől származó kereszt-modulációs termékek iránti érzékenység csökkentést és védettséget. Ezek a követelmények a
"B"-Függelék 3.6.8.2.2 pontjában találhatók;

d) A VOR vevők teljesítményét, beleértve a közös-csatorna és szomszédos csatorna csillapítást a VHF adat sugárzás (VDB) jeleire. Mivel a meglévő VOR vevők nem kifejezetten úgy voltak megtervezve, hogy elnyomják a VHF adat sugárzás adásait, a megkívánt – nem-kívánt (D/U) jel arányok a VHF adat sugárzás /VDB/ közös csatorna és szomszédos csatorna elnyomása tapasztalati alapon kerültek meghatározásra. A D-2. táblázat összegzi az elfogadott jel arányokat nagyszámú 50 kHz-s csatorna-elosztással tervezett VOR vevő tapasztalati teljesítményeire alapozva;

e) A frekvencia „zsúfoltságú" területeken/körzetekben a frekvencia szétválasztás pontos meghatározására lehet szükség a megfelelő követelmények alkalmazásával.
7.2.1.1.2 A VHF adat sugárzás /VDB/ névleges kapcsolat kiosztása a D-3. táblázatban kerül bemutatásra. A táblázatban elfogadott számok egy 3000 m-es (10 000 láb) közepes tengerszint feletti magasságra /MSL/ és olyan adó antennára épülnek, amelyet úgy terveztek, hogy elnyomja a földi besugárzást abból a célból, hogy a halkulási veszteséget a fedésterület határvonalainál egy maximális 10 dB-es értékre korlátozza. A GBAS/E berendezés esetében a 10 dB magában foglalja még a vízszintes és függőleges összetevők közötti interferencia miatti jel veszteség bármilyen hatását is.

7.2.1.2 *Frekvenciamodulációs /FM/ érzéketlenség*

7.2.1.2.1 Miután a 'tervezett' frekvencia azonosításra került, az, amely a GBAS és a VOR frekvencia elválasztási követelményeket kielégíti, meg kell határozni a frekvenciamodulációs /FM/ továbbítással való összeférhetőségét is. Ezt úgy kell elvégezni, hogy azt a módszert kell alkalmazni, mint amit az FM-nek a VOR-ral történő összeegyeztethetőségénél használtak. Ha az FM sugárzás megsérti ezt a követelményt, akkor egy választható kijelölt frekvenciát kell figyelembe venni.

D-2. táblázat: Elfogadott Megkívánt $[D/U]_{required}$ jel arányok a VOR-nak a GBAS VHF adat sugárzás /VDB/ elleni védelméhez

Frekvencia eltolás	A VOR vevők védelméhez szükséges $[D/U]_{required}$ arány (dB)
Közös csatorna	26
$\mid f_{VOR} – f_{VDB} \mid$ = 25 kHz	0
$\mid f_{VOR} – f_{VDB} \mid$ = 50 kHz	–34
$\mid f_{VOR} – f_{VDB} \mid$ = 75 kHz	–46
$\mid f_{VOR} – f_{VDB} \mid$ = 100 kHz	–65

D-3. táblázat: Névleges VHF adat sugárzási /VDB/ kapcsolat kiosztás

VHF adat sugárzási /VDB/ kapcsolat elemek	A kapcsolat kiosztás függőleges elemei a fedésterület határánál	A kapcsolat kiosztás vízszintes elemei a fedésterület határánál
Szükséges vevő érzékenység (dBm)	–87	–87
Maximális légijármű kivitelezési veszteség (dB)	11	15
A légijármű antennája utáni teljesítmény szint (dBm)	–76	–72
Üzemeltetési határérték (dB)	3	3
Jel-feszültség csökkenési határérték (dB)	10	10
Szabadtér-beli jel út veszteség (dB) 43 km-nél (23 tengri mérföld)	106	106
Névleges kisugárzott teljesítmény (dBm)	43	47

7.2.1.2.2 Az érzéketlenítés nincs alkalmazva a 107,7 MHz feletti FM vivőhullámokra és a 108,050 MHz-es VHF adat sugárzó /VDB/ csatornákra, azért, mert az ilyen magas szintű sugárzások csatornán kívüli összetevői a 107,7 MHz feletti FM állomásoktól zavarni fogják a Földi Bázisú Kiegészítő Rendszer /GBAS/ VHF adat sugárzási (VDB) üzemeltetéseket a 108,025 és a 108,050 MHz-en, ennélfogva ezeket a kijelöléseket ki kell zárni, kivéve bizonyos speciális kijelöléseknél, az olyan földrajzi területeken, ahol a működő FM sugárzó állomások száma kevés, és az interferencia létrehozása a VHF adat sugárzó vevőknél valószínűtlen.

7.2.1.2.3 A frekvencia-modulációs /FM/ kereszt-modulációs érzéketlenségi követelmények nem alkalmazandók a 108,1 MHz alatt üzemelő VDB csatornákra, ennélfogva a 108,1 MHz alatti kijelöléseket ki kell zárni, kivéve bizonyos speciális kijelöléseknél, az olyan földrajzi területeken, ahol a működő FM sugárzó állomások száma kevés, és nem valószínű az, hogy kereszt-modulációs termékeket hoznak létre a VDB vevőknél.

7.2.1.3 *Földrajzi elkülönítési módszerek*

7.2.1.3.1 Az alábbi módszereket lehet felhasználni a GBAS –GBAS közötti, valamint a GBAS – VOR közötti szükséges földrajzi elkülönítés meghatározásához. Ezek arra támaszkodnak, hogy megvédjék a minimális megkívánt – nem-kívánt jel arányt. A $[D/U]_{required}$ úgy van meghatározva, mint az a jel arány, amelyet arra tervezetek, hogy megvédje a megkívánt jelet egy nem-kívánt adás közös csatorna, vagy szomszédos csatorna interferenciájától. A $[D/U]_{required}$ értékei, amelyek a GBAS vevőnek a nem-kívánt GBAS, vagy VOR jelektől való védelméhez szükségesek, a "B"- Függelék 3.6.8.2.2.5 és 3.6.8.2.2.6 pontjában kerültek meghatározásra. Azok a $[D/U]_{required}$ értékek, amelyek a VOR vevőnek a GBAS VHF Adat-sugárzás /VDB/ adásaitól való védelmére szántak – ahogy azt a D-2. Táblázat bemutatja – nem kerültek a Szabványok és Ajánlott Gyakorlatokban /SARPs/ meghatározásra, és azokat az elfogadott értékeket mutatják be, amelyek ellenőrző méréseken alapulnak.

7.2.1.3.2 A földrajzi elkülönítés leszűkítésre került a $[D/U]_{required}$ megvédésére a megkívánt jel fedésterület határvonalánál, ahol a megkívánt jel teljesítményt a 3. Fejezetben lévő minimális térerő követelményekből vezették le. A megkívánt jelszint, dBm-re átalakítva, $P_{D,min}$-ként van jelölve. A nem-kívánt jelre megengedett ($P_{U,allowed}$) jel teljesítmény a következő:

$$P_{U,allowed}\,(\text{dBm}) = (P_{D,min}\,(\text{dBm}) - [D/U]_{required}\,(\text{dBm}))$$

A nem-kívánt jel teljesítmény, a P_U dBm-re átalakítva:

$$P_U\,(\text{dBm}) = (Tx_U\,(\text{dBm}) - L\,(\text{dB}))$$

ahol:

Tx_U = a nem-kívánt jel adójának kisugárzott teljesítménye; és

L = a nem-kívánt jel adójának átviteli vesztesége, beleértve a szabad-térbeli átviteli veszteséget, az atmoszférikus és föld hatásokat. Ez az átviteli veszteség a nem-kívánt jel adója és a megkívánt jel fedésterületi körzetének határa közötti távolságtól függ.

Annak biztosítására, hogy a $D/U_{required}$ kielégítésre kerüljön, a P_U kisebb, egyenlő, mint $D_{U,allowed}$.

Egy csatorna kijelölésének a korlátozása ennek megfelelően:

$$L(\text{dB}) \geq ([D/U]_{required}\,(\text{dB}) + Tx_U\,(\text{dBm}) - P_{D,min}\,(\text{dBm}))$$

7.2.1.3.3 Az átviteli veszteséget az ITU-R Ajánlás P.528-2-ben lévő szabvány terjedési modellből lehet megkapni, vagy a rádióhorizontig terjedő szabadtérbeli csillapításból és azután egy állandó 0,5 dB/tengeri mérföld csillapítási tényezőből. Ez a két módszer egy kissé eltérő földrajzi elkülönítést eredményez a közös csatornára és az első szomszédos csatornákra, és azonos elkülönítést, amint a második szomszédos csatorna kerül figyelembevételre. A szabadtérbeli terjedés közelítése alkalmazásra került ebben az útmutató anyagban.

7.2.1.4 *Példa a GBAS/GBAS földrajzi elkülönítési követelményekre*

7.2.1.4.1 A GBAS VHF adat sugárzás /VDB/ közös csatornájú átvitelére, amely azonos időrésre van kiosztva, a vízszintes polarizáció paraméterei a következők:

D/U	=	26 dB ("B"- Függelék 3.6.8.2.2.5.1 pont);
$P_{D,min}$	=	–72 dBm (ez megfelel 215 mikrovolt/méter-nek, 3. Fejezet 3.7.3.5.4.4 pontja); és
Tx_U	=	47 dBm (kapcsolt kiosztás példa, D-2. Táblázat);

Ennek megfelelően:

$$L \geq (47 + 26 - (-72)) = 145\ \text{dB}.$$

7.2.1.4.2 A közös csatornájú, közös résidejű GBAS VDB kiosztások földrajzi elkülönítését úgy lehet megkapni, hogy meghatározzák azt a távolságot, amelynél az átviteli veszteség 145 dB-el egyenlő a 3000 m-es (10 000 láb) tengerszint feletti magasságon, azon pont felett, ahol a GBAS VDB adó antennája van. Ez a távolság 318 km (172 tengeri mérföld) egy szabadtér-beli csillapítási megközelítést használva és egy elfogadható adó antenna magasságot figyelembe véve. Ezután a minimális szükséges földrajzi elkülönítést meg lehet határozni ennek a távolságnak a GBAS adó 43 km-es (23 tengeri mérföld) távolsága és a fedésterület határvonala közötti névleges távolsághoz történő hozzáadásával. Ez egy közös csatornájú, közös résidejű 361 km-es (195 tengeri mérföld) újrafelhasználási távolságot eredményez.

7.2.1.5 *Irányvonalak a GBAS/GBAS földrajzi elkülönítési követelményhez.* A fentiekben leírt módszer alkalmazásával jellemző földrajzi elkülönítési követelményeket lehet meghatározni a GBAS – GBAS és a GBAS – VOR elkülönítésekre. A létrejövő GBAS – GBAS közötti minimálisan szükséges földrajzi elkülönítési követelmények eredményei a D-4. Táblázatban kerültek összefoglalásra.

Megjegyzés. – Az olyan GBAS adók közötti földrajzi elkülönítési követelmények, amelyek GBAS helymeghatározási szolgáltatást biztosítanak, kidolgozás alatt állnak. Körültekintő értékeket – amelyek a rádióhorizontnak felelnek meg – lehet alkalmazni ideiglenes értékként az azonos frekvenciájú, szomszédos idősésű adókra annak biztosítására, hogy az időrések nem fognak átfedést adni.

7.2.1.6 *Irányvonalak a GBAS/VOR földrajzi elkülönítési követelményekhez.* A GBAS/VOR minimális földrajzi elkülönítési követelmények a D-5. Táblázatban kerültek összefoglalásra, ezek ugyanazon a módszeren és névleges VOR fedésterület kiterjedésen alapulnak, mint ami a ”C”- Mellékletben található.

1. Megjegyzés. – Amikor a VOR és a GBAS közötti földrajzi elkülönítés meghatározásra kerül, akkor a VOR mint megkívánt jel, a korlátozó eset általában a VOR fedésterületei körzetének nagyobb védettségi magassága miatt.

2. Megjegyzés. – Csökkentett földrajzi elkülönítési követelményeket lehet elérni az ITU-R Ajánlás P.528-2-ben meghatározott szabvány terjedési modellek alkalmazásánál.

D-4. táblázat: A jellemző GBAS/GBAS frekvencia kijelölési követelmény

A nem-kívánt VDB csatorna azonos időrésben	Útvonal veszteség (dB)	Minimális szükséges földrajzi elkülönítés a TxU = 47 dBm-re és PD,min = –72 dBm-re km-ben (tmf)
Közös csatorna	145	361 (195)
1. szomszédos csatorna (±25 kHz)	101	67 (36)
2. szomszédos csatorna (±50 kHz)	76	44 (24)
3. szomszédos csatorna (±75 kHz)	73	Nincs korlátozás.
4. szomszédos csatorna (±100 kHz)	73	Nincs korlátozás.

Megjegyzés. – Nem várhatóak földrajzi adó korlátozások a közös frekvenciájú szomszédos idősésű adók között, feltéve, hogy a nem-kívánt jelű VDB sugárzó antenna legalább 200 m-re van azoktól a területektől, ahol a megkívánt jel a minimális térerőnél van.

D-5. táblázat: A minimális szükséges földrajzi elkülönítés egy VOR fedésterületre (12 000 m (40 000 láb) szinten)

Nem-kívánt GBAS VDB csatorna	Útvonal veszteség (dB)	A V OR fedésterület sugara		
		342 km (185 tengeri mérföld)	300 km (162 tengeri mérföld)	167 km (90 tengeri mérföld)
Közös csatorna	152	892 km (481 tengeri mérföld)	850km (458 tengeri mérföld)	717km (386 tengeri mérföld)
$\lvert f_{Megkívánt} - f_{Nem\text{-}kívánt} \rvert = 25$ kHz	126	774 km (418 tengeri mérföld)	732 km (395 tengeri mérföld)	599 km (323 tengeri mérföld)
$\lvert f_{Megkívánt} - f_{Nem\text{-}kívánt} \rvert = 50$ kHz	92	351 km (189 tengeri mérföld)	309 km (166 tengeri mérföld)	176 km (94 tengeri mérföld)
$\lvert f_{Megkívánt} - f_{Nem\text{-}kívánt} \rvert = 75$ kHz	80	344 km (186 tengeri mérföld)	302 km (163 tengeri mérföld)	169 km (91 tengeri mérföld)
$\lvert f_{Megkívánt} - f_{Nem\text{-}kívánt} \rvert = 100$ kHz	61	Nincs korlátozás.	Nincs korlátozás.	Nincs korlátozás.

Megjegyzés. – A számítások a 112 MHz-es referencia frekvencián alapulnak és a GBAS Tx_U = 47 dBm és a VOR $P_{D,min}$ = –79 dBm.

7.2.2 A GBAS/ILS és a GBAS/VHF hírközlés földrajzi elkülönítési követelményei kidolgozás alatt állnak.

7.2.3 *Az ILS-el való kompatibilátás.* Addig, amíg a GBAS VDB és az ILS kompatibilitási követelményei kidolgozásra nem kerülnek, a VHF adat sugárzást /VDB/ nem lehet kijelölni a 112,025 MHz alatti csatornákra. Amikor egy magas frekvencia kijelölésű ILS van ugyanazon a repülőtéren, ahol a VHF adat sugárzás /VDB/ frekvenciája a 112 MHz közelében van, akkor szükségszerűen figyelembe kell venni az ILS és a VDB kompatibilitását. A VDB csatornák kijelölésének megfontolásai magukba foglalják az ILS és a VDB közötti frekvencia elkülönítést, az ILS fedésterülete és a VDB közötti távolsági elkülönítést, a VDB és az ILS térerősségét, valamint a VDB és az ILS érzékenységét. Egy GBAS berendezésre – aminek az adó teljesítménye 150 W-ig terjedő (GBAS/E), 100 W a vízszintes összetevőre és 50 W a függőleges összetevőre, vagy 100 W (GBAS/H), a 16. csatornájának (és azon túl) –106 dBm-el alatta kell lenni a VDB adótól 200 m-es távolságnál, beleértve egy +5 dB-es pozitív visszaverődés figyelembevételét is. Ez a –106 dBm-es számjegy egy –86 dBm-es iránysávadó jelet feltételez az ILS vevő bemenetén és egy minimális 20 dB-es jel-zaj arányt.

7.2.4 *Kompatibilitás a VHF összeköttetésekkel.* A 116,400 MH-es GBAS VHF adat sugárzásnál /VDB/ szükségszerű a VHF összeköttetések és a GBAS VDB kompatiblitásának számításba vétele. Ezeknek a VDB csatornáknak a kijelölésénél a meggondolások magukba foglalják a VHF összeköttetések és a VDB közötti frekvencia elkülönítést, az adók és a fedésterületi körzetek közötti távolsági elkülönítést, a térerőket, a VDB jel polarizációját, valamint a VDB és a VHF érzékenységét. Mindkettőt, a légijármű fedélzeti (mozgó) és a légiforgalmi irányítási (állandó-helyű) VHF összeköttetési berendezéseket is számításba kell venni.
Egy GBAS/E berendezésre, aminek a maximális adó teljesítménye 150 W-ig terjedő, (100 W a vízszintes összetevőre és 50 W a függőleges összetevőre) a 64. csatornájának (és azon túl) –120 dBm-el alatta kell lenni a VDB adótól 200 m-es távolságnál, beleértve egy +5 dB-es pozitív

visszaverődés figyelembevételét is. Egy GBAS/H berendezésre – aminek az adó maximális teljesítménye 100 W terjedő – a 32. csatornájának (és azon túl) –120 dBm-el alatta kell lenni a VDB adótól 200 m-es távolságnál, beleértve egy +5 dB-es pozitív visszaverődés figyelembevételét, valamint egy 10 dB-es polarizációs elkülönítést is. Meg kell jegyezni azt, hogy a VHF adat sugárzás /VDB/ és a VHF adat összeköttetés /VDL/ adó maszkjának különbségei miatt különálló elemzést kell végezni annak biztosítására, hogy a VDL ne zavarja /interferencia/ a VDB-t.

7.2.5 Egy olyan GBAS földi al-rendszernél, ami csak egy vízszintesen polarizált jelet sugároz, azt a követelményt, hogy elérjék a minimális érzékenységhez kapcsolódó teljesítményt, a térerő követelményen keresztül közvetlenül ki lehet elégíteni. Egy olyan GBAS földi al-rendszernél, ami ellipszis polarizációjú összetevőkkel sugároz, a Vízszintes Polarizációjú /HPOL/ és a Függőleges Polarizációjú /VPOL/ összetevők közötti ideális fáziseltolás 90 fokos. Abból a célból, hogy biztosítva legyen az, hogy a megfelelő vett teljesítmény a szabályos légijármű manőverek során a GBAS teljes fedésterületén megmaradjon, a sugárzó berendezéseket úgy kell megtervezni, hogy a HPOL és VPOL jel összetevőket egy 90 fokos RF fáziseltolással sugározzák. Ennek a fáziseltolásnak állandónak kell maradni az idő és a környezeti körülmények minden esetén. A névleges 90 foktól való eltérést számításba kell venni a rendszer tervezésnél és a kapcsolat kiosztásnál, úgy, hogy a polarizációs veszteség miatti bármilyen elhalkulás /fading/ ne veszélyeztesse a minimális vevő érzékenységet. Rendszer minősítési és légi ellenőrzési eljárások fogják számításba venni a fáziseltolásnak azt a megengedhető eltérését, ami összeegyeztethető a GBAS fedésterülete kiterjedésének teljes egészében az előirányzott jelszinttel. Mindkét, a vízszintes és a függőleges térerő biztosításának az egyik módja az egy olyan egyedüli VDB antenna használata, ami egy elliptikusan polarizált jelet sugároz, és repülés közben ellenőrzi a függőleges és vízszintes jelek tényleges térerősségét a fedésterületen belül.

7.3 Fedésterület

7.3.1 Az I. Kategóriájú precíziós megközelítést alátámasztó GBAS fedésterületet a D-4. ábra rajzolja le. Amikor a kiegészítő efemerisz-hiba helyzet határ paraméterek sugárzásra kerülnek, akkor a differenciális helyesbítéseket csak a 2. Típusú közleményben meghatározott maximális felhasználási távolságon (D_{max}) belül lehet felhasználni.

7.3.2 A GBAS helymeghatározási szolgáltatás alátámasztásához szükséges fedésterület a tervezett különleges üzemeltetések függvénye. Erre a szolgáltatásra az optimális fedésterület ’körsugárzóként’ tervezett abból a célból, hogy alátámassza azokat az üzemeltetéseket, amelyeket a GBAS helymeghatározási szolgáltatás precíziós megközelítési fedésterület légterén kívül hajtanak végre. Nem várható az, hogy a GBAS fedésterületét megnöveljék arra a célra, hogy az a helymeghatározási szolgáltatást is ellássa.

7.3.3 A GBAS helymeghatározási szolgáltatás felhasználhatóságának határát a Maximális felhasználási távolság /D_{max}/ adja meg, ami azt a legnagyobb távolságot határozza meg, amelyen belül a megkívánt sértetlenség /integritás/ biztosítva van, és a differenciális helyesbítéseket mind a helymeghatározási szolgáltatásra, mind a precíziós megközelítésre fel lehet használni.
Azonban a D_{max} nem ’körvonalazza’ azt a fedésterületet, ahol a 3. Fejezet 3.7.3.5.4.4 pontjában meghatározott térerősségi követelmények kielégítésre kerülnek, és nem is egyezik meg ezzel a területtel. Ennek megfelelően a GBAS helymeghatározási szolgáltatásra alapozott üzemel-tetéseket csak azon a fedésterület(ek)en belülre lehet alapozni, ahol a térerősség követelmények teljesülnek a D_{max} távolságon belül.

7.4 Adat szerkezet

Egy bit rejtjelező/rejtjelfejtő a D-5. ábrán került bemutatásra.

Megjegyzés. – A VHF adat sugárzás adat szerkezetére vonatkozó kiegészítő tájékoztatások az RTCA/DO-246B-ben, a GNSS Alapú Precíziós Megközelítés Helyi Körzeti Kiegészítő Rendszer (LAAS) – Térbeli-jel Interferencia Ellenőrző Dokumentum-ban (ICD) *találhatók.*

7.5 Sértetlenség

7.5.1 Különböző sértetlenségi szintek kerültek meghatározásra a precíziós megközelítési üzemeltetésekre és a GBAS helymeghatározási szolgáltatásra alapozott üzemeltetésekre. A térbeli-jel sértetlenségi veszély az I. Kategóriájú megközelítésenként 2×10^{-7}. Azoknak a földi al-rendszereknek, amelyeket a GBAS helymeghatározási szolgáltatás felhasználásával egyéb üzemeltetések végrehajtásának alátámasztására is terveztek, ki kell elégíteniük a közelkörzeti üzemeltetésekre meghatározott térbeli-jel sértetlenségi követelményeket, ami óránként 1×10^{-7} (3. fejezet 3.7.2.4.-1 táblázat). Ennek megfelelően kiegészítő lépésekre van szükség a helymeghatározási szolgáltatásoknak a jóval szigorúbb követelményű alátámasztására. A térbeli-jel sértetlenségi veszély fel van osztva a földi al-rendszer sértetlenségi veszélyre és a védelmi szint sértetlenségi veszélyre. A földi al-rendszer sértetlenségi veszély rész a földi al-rendszer hibáit, valamint a műhold helyzet-sor rendszer és a Műhold Bázisú Kiegészítő Rendszer /SBAS/ hibákat fedi úgy, mint jel minőség-hibákat és efemerisz-hibákat. A védelmi szint sértetlenségi veszély rész a ritka hibamentes teljesítmény veszélyeket és az egy referencia vevő mérései hibáinak esetét fedi. Mindkét esetben a védelmi szint egyenletek biztosítják azt, hogy a légijármű fedélzeti vevője által felhasznált műhold geometriai hatások számításba vételre kerüljenek. Ez a következő pontokban kerül jóval részletesebben leírásra.

7.5.2 A Földi Bázisú Kiegészítő Rendszer /GBAS/ földi al-rendszer meghatároz egy helyesbített pszeudo-távolság hiba bizonytalanságot a referencia pontra (σ_{pr_gnd}) vonatkozó hibára, valamint a függőleges (σ_{tropo}) és a vízszintes (σ_{iono}) térbeli dekorrelációból eredő hibákra. Ezek a bizonytalanságok nulla-átlagú normál szórásnégyzetes értékeivel vannak modellezve, amelyek ezeket a hibákat az egyes távolság-meghatározási forrásokra leírják.

7.5.3 A fentiekben leírt egyedi hiba bizonytalanságokat használja fel a vevő a navigációs megoldásnál a hiba modell kiszámításához. Ezt úgy végzi, hogy kivetíti a pszeudo-távolságot a helyzet tartományra. Az általános módszerek annak meghatározásához, hogy a modell szórásnégyzet kielégítő-e a védelmi szint sértetlenségi veszély biztosításához, a 13. részben kerülnek leírásra. Az Oldalirányú Védelmi Szint (LPL) biztosítja az oldalirányú helyzet hiba határolást egy olyan valószínűséggel, amit a sértetlenségi követelményből származtat. Hasonlóképpen a Függőleges Védelmi Szint (VPL) biztosítja a függőleges helyzet határolást. Az I. Kategóriájú precíziós megközelítésre, ha a számított LPL meghaladja az Oldalirányú Riasztási Határértéket (LAL), vagy a VPL meghaladja a Függőleges Riasztási Határértéket (VAL), akkor a sértetlenség nem kielégítő ahhoz, hogy az üzemelést alátámassza.
A helymeghatározási szolgáltatásra nem kerültek a szabványban riasztási határértékek meghatározásra, csak az, hogy a vízszintes védelmi szintet és az efemerisz-hiba helyzet határokat kell kiszámítani és alkalmazni. A riasztási határértékek a végrehajtott üzemeltetésekre alapozva kerülnek meghatározásra. A légijármű alkalmazni fogja a kiszámított védelmi szintet és efemerisz-hiba határértékeket, és ellenőrzi azt, hogy azok kisebbek-e mint a riasztási határértékek. Két védelmi szint került meghatározásra, az egyik, amely azt a helyzetet célozza meg, amikor az összes referencia vevő hibamentes (H_0 - Szabvány Mérési Körülmények) és a másik, ami azt a helyzetet, amikor a referencia vevők egyike hibás méréseket tartalmaz (H_1 - Hibás Mérési Körülmények). Kiegészítésképpen egy efemerisz-hiba helyzet határ határértéket biztosít a távolságmérési forrás efemerisz-hibája miatti helyzet hibákhoz is. Az I. Kategóriájú precíziós megközelítésekre egy oldalirányú határérték /LEB/ és egy függőleges határérték /VEB/ került meghatározásra. A helymeghatározási szolgáltatásra a vízszintes efemerisz-hiba határérték /HEB/ van meghatározva.

7.5.4 *A földi rendszer hozzájárulása a helyesbített pszeudo-távolság hibához (σpr_gnd).* Azok a hibaforrások, amelyek ehhez a hibához hozzájárulnak, a vevő zaját, a többutas visszaverődést és az antenna fázis-középpontjának a kalibrálásában jelentkező hibákat foglalják magukba. A vevő zajnak egy nulla-átlagú normál eloszlású hibája van, míg a több-utas visszaverődés és az antenna fázis-középpont kalibrálás egy kis négyzetes közép hibát eredményezhet.

7.5.5 *Megmaradó troposzférikus hibák.* A troposzférikus paraméterek a 2. Típusú közleményekben kerülnek továbbításra a troposzféra hatásainak modelezésére, amikor a légijármű a referencia ponttól eltérő magasságban van. Ezt a hibát jól le lehet írni egy nulla-átlagú normál eloszlással.

7.5.6 *Megmaradó ionoszférikus hibák.* Egy ionoszférikus paraméter kerül a 2. Típusú közleményekben sugárzásra az ionoszférikus hatásoknak a referencia pont és a légijármű közötti hatásai modellezésére. Ezt a hibát jól le lehet írni egy nulla-átlagú normál eloszlással.

7.5.7 *A légijármű fedélzeti vevőjének hozzájárulása a helyesbített pszeudo-távolság hibához.* A vevő hozzájárulása úgy van határolva, ahogy az a 13. Részben leírásra került. Azt a maximális hozzájárulást, ami a GBAS szolgáltatás biztosító által elemzésre használatos, a pontossági követelményből lehet venni, ahol az az elfogadott, hogy a $\sigma_{receiver}$ egyenlő az RMS_{pr_air}-el a GBAS A-jelölésű Repülési Pontosságú berendezésre.

7.5.8 *Repülőgép test többutas visszaverődési hiba.* A repülőgép test többutas visszaverődéséből eredő hiba hozzájárulás a "B"-Függelék 3.6.5.5.1 pontjában került meghatározásra. A más egyéb tárgyakról való tükröződésekből eredő többutas szóródási hibák nem kerültek figyelembevételre. Ha a tapasztalatok azt jelzik, hogy ezek a hibák nem elhanyagolhatóak, akkor ezeket számításba kell venni üzemeltetési szempontból, vagy a földfelszín által (vissza)sugárzott paraméterek megnövekedésén keresztül (azaz σ_{pr_gnd}).

7.5.9 *Efemerisz-hiba bizonytalanság.* Az efemerisz-hibák eredményeként létrejövő pszeudo-távolság hibák (amik úgy kerültek meghatározásra, mint a tényleges műhold helyzet és a sugárzott adatokból meghatározott műhold helyzet közötti eltérés) térbelileg dekorreláltak, és ennek megfelelően különbözőek lesznek a különböző helyeken lévő vevők részére. Amikor a felhasználók viszonylag közel vannak a GBAS referencia ponthoz, az efemerisz-hibák miatti differenciál hibák kicsik lesznek, és mind a helyesbítések, mind a bizonytalansági paraméterek, σ_{pr_gnd} , amelyeket a földi al-rendszer küld, érvényesek lesznek ahhoz, hogy a durva méréseket helyesbítsék, és a védelmi szintet kiszámítsák. Azoknak a felhasználóknak a részére, akik távolabb vannak a GBAS referencia ponttól, az efemerisz-hibák elleni védelmet két eltérő módon lehet biztosítani:

a) a földi al-rendszer nem sugározza a kiegészítő efemerisz-hiba helyzet határ paramétereket. Ebben az esetben a földi al-rendszer felelős a sértetlenség biztosításáért, a műhold efemerisz-hibák esetében, anélkül, hogy a légijárművek az efemerisz határokat kiszámítanák és alkalmaznák. Ez korlátozást okozhat a GBAS referencia pont és az elhatározási tengerszint feletti magasság/repülőtér feletti magasság közötti távolságban, attól függően, hogy a földi al-rendszer figyelembe veszi-e a távolság-mérési forrás efemerisz-hibák megállapítását. A 'megállapítás' egyik eszköze az SBAS által sugárzott műhold sértetlenségi információk felhasználása; és

b) a földi al-rendszer egy olyan kiegészítő efemerisz-hiba helyzet paramétert ad le, ami lehetővé teszi a légijármű fedélzeti vevője részére azt, hogy kiszámítsa az efemerisz-hiba határt. A paraméterek a következők: az efemerisz-hiba helyzet határ egyenletekben használt ($K_{md\_e\_()}$) együttható, ahol a () jelölés jelentése: "GPS", "GLONASS", "POS,GPS", vagy "POS GLONASS"; a differenciál helyesbítésekhez használt maximális felhasználási távolság, a (D_{max}), és az efemerisz dekorrelációs paraméterek (P). Az 1. Típusú közleményben lévő (P) efemerisz dekorrelációs paraméter úgy írja le a megmaradó hibát, hogy az a referencia pont és a légijármű közötti távolság függvénye. A P értékei m/m-ben vannak kifejezve. A P értékeit a földi al-rendszer az egyes műholdakra határozza meg. A P értékeit befolyásoló fő tényezők egyike a földi al-rendszer ellenőrző egységének felépítése. A földi ellenőrző berendezés minőségét az a legkisebb efemerisz-hiba (vagy a Minimális Kimutatható Hiba (MDE)) fogja leírni, amit ki tud mutatni. Egy meghatározott műholdra a P paraméter és az MDE közötti összefüggést a $P_i = MDE_i/R_i$ képlettel lehet közelíteni, ahol az R_i a földi al-rendszer referencia vevő antennájá(i)tól az előre jelzett távolságokból a legkisebb, a P_i érvényességi időtartam alatt. Mivel ez a műhold geometriától függő, a P paraméterek értékei lassan változóak. Azonban a földi al-rendszer részére nem követelmény a dinamikusan változó P. Ha statikus P paramétereket lehetne küldeni, akkor azok teljesen biztosítanák a sértetlenséget. Ebben az utóbbi esetben az elérhetőség kismértékben lecsökkenne. Általánosan ahogy az MDE értéke kisebbé válik, úgy az átfogó GBAS elérhetőség javul.

7.5.10 *Efemerisz-hiba/meghibásodás ellenőrzés.* Több különféle típusú ellenőrzési megközelítése van az efemerisz-hibáknak/meghibásodásoknak, ezek:

a) Hosszú alapvonal. Ez a földi al-rendszernél azt teszi szükségessé, hogy egymástól elkülönített és nagy távolságban elhelyezett vevőket használjon az olyan efemerisz-hibák kimutatására, amelyek egy egyedüli vevővel nem érzékelhetők. A hosszabb alapvonalak az MDE-n belüli jobb teljesítményre vezetnek;

b) SBAS. Mivel az SBAS kiegészítő rendszer, biztosítja a műhold teljesítményének ellenőrzését, az efemerisz adatokat is beleértve, így az SBAS által sugárzott sértetlenségi információkat fel lehet használni az efemerisz érvényességének jelzéseként. Az SBAS felhasználása a földi al-rendszernél a vevők nagyon hosszú alapvonalon való telepítését igényli, ennek megfelelően ez optimális teljesítményt biztosít az efemerisz ellenőrzéséhez, és ezáltal kis MDE-k érhetők el; és

c) Efemerisz adat ellenőrzés. Ez a megközelítés azt foglalja magába, hogy a sugárzott efemeriszek az egymás után következő műhold körönként összehasonlításra kerülnek. Van egy olyan feltételezés, hogy a csak az efemerisz-hiba miatti hiba veszély a műhold helyzetsor földi vezérlő hálózatából ered. A manőverezési utasítás nélküli műhold manőverei miatti hibák valószínűtlenségének elegendőnek kell lenni ahhoz, hogy ez a megközelítés a szükséges sértetlenséget biztosítsa.

7.5.10.1 Az ellenőrző rendszer felépítése (példaként az, ami a Minimális kimutatható hibával /MDE/ érhető el) a sértetlenségi veszély követelményeken és azon a hiba modellen alapszik, amely elleni védelemre az ellenőrző rendszert szánják. A GPS efemerisz-hiba határt a 3.fejezet 3.7.3.1.3 pontjában megadott megbízhatósági követelményekből lehet meghatározni, mivel így egy efemerisz-hiba az a hiba, ami egy nagyobb szolgáltatási hibát képezne.

7.5.10.2 A GLONASS vezérlő része az efemerisz és idő paramétereket ellenőrzi, és bármilyen rendellenes helyzetben megkezdi az új és pontos navigációs közlemény leadását. Az efemerisz- és idő paraméter hibák nem haladják meg a 70 méteres távolságmérési hibákat. A GLONASS műhold hiba gyakorisága az efemerisz és idő paraméter hibákat is beleértve nem haladja meg a 4×10^{-5} -t műholdanként és óránként.

7.5.11 Egy tipikus GBAS földi al-rendszer a referencia pont közvetlen szomszédságában telepített 2-4 referencia vevő méréseit dolgozza fel. A repülőgép vevője nagyszámú hiba, vagy hiba állapot ellen védett egy egyedülálló referencia vevőben úgy, hogy az 1. Típusú, vagy a 101. Típusú közleményből származó B paramétereket feldolgozzák és összehasonlítják a különböző referencia vevőből származó adattal. A referencia vevő mérésekben megfelelően felépített redundanciával rendelkező alternatív rendszer kialakítások alkalmazhatnak olyan feldolgozó algoritmusokat, melyek képesek azonosítani nagyszámú hibákat, vagy meghibásodásokat az egyes vevőkben. Ez felhasználható egy széles területen elosztott vevőkkel és ionoszférikus áthatolási pontok megfelelő sűrűségével rendelkező GRAS hálózatnál arra, hogy elkülönítsék a vevő hibákat az ionoszférikus hatásoktól. A sértetlenség (integritás) megvalósítható csak a védelmi szintek használatával a normál mérési állapotoknál (VPL_{HO} és LPL_{HO}), a megfelelő K_{ffmd} és σ_{pr_gnd} értékekkel. Ez a B paramétereket nem tartalmazó 101. Típusú közlemény használatával valósítható meg.

7.6 A szolgáltatás folyamatossága

7.6.1 *A földi folyamatossági és sértetlenségi kijelölő.* A földi folyamatossági és sértetlenségi kijelölő (GCID) a GBAS földi al-rendszerek osztályozását biztosítja. A földi al-rendszer kielégíti az I. Kategóriájú precíziós megközelítési, vagy az APV követelményeket akkor, amikor a GCID 1-re van állítva. A GCID 2, 3 és 4 olyan jövőbeli üzemeltetések alátámasztására vannak tervezve, amelyek követelményei jóval szigorúbbak, mint az I. Kategóriájú üzemeltetéseké. A GCID a földi rendszer állapotának egy olyan tervezett jelzése, ami akkor használatos, amikor egy légijármű kiválaszt egy megközelítést. Nem az a célja, hogy helyettesítse, vagy kiegészítse az 1. Típusú közleményekben közölt folyamatos sértetlenségi jelzéseket. A GCID nem biztosít semmilyen jelzést a földi al-rendszernek a GBAS helymeghatározási szolgáltatás alátámasztási képességéről.

7.6.2 *A földi al-rendszer szolgáltatási folyamatossága.* A GBAS földi al-rendszerekkel szemben az az elvárás, hogy feleljenek meg a "B"- Függelék 3. fejezetének 3.6.7.1.3 pontjában meghatározott folyamatosságnak azzal a céllal, hogy az I. Kategóriájú precíziós megközelítést és az APV-t alátámasszák.
Azoknak a GBAS földi al-rendszereknek, amelyek arra a célra is szolgálnak, hogy más üzemeltetéseket is alátámasszanak, a GBAS helymeghatározási szolgáltatás felhasználásán keresztül teljesíteniük kell a közelkörzeti területi működéshez szükséges minimális folyamatossági követelményt, ami $1 - 10^{-4}$/óra. (3. fejezet 3.7.2.4-1. táblázat). Amikor az I. Kategóriájú precíziós megközelítésre megkívánt folyamatosság ($1 - 3{,}3 \times 10^{-6}$/15 másodperc) óránkénti értékre kerül átalakításra, akkor az nem elégíti ki az $1 - 10^{-4}$/óra minimális folyamatossági követelményt. Ennek megfelelően kiegészítő intézkedések szükségesek ahhoz, hogy az egyéb üzemeltetések által megkívánt folyamatosság kielégíthető legyen. Az egyik módszer a teljesítés igazolására annak elfogadása, hogy a légijármű fedélzeti rendszere felhasználja mind a Földi Bázisú Kiegészítő Rendszert /GBAS/, mind a Légijármű Bázisú Kiegészítő Rendszert /ABAS/ a tartalék biztosításához, és azt, hogy az ABAS kielégítő pontosságot biztosít a tervezett üzemeltetéshez.

7.7 GBAS csatorna kiválasztás

7.7.1 A GBAS-nél használt csatorna számok megkönnyítik az illeszkedést a légijármű berendezése és azon térbeli-jel között, ami összhangban van az ILS-el és az MLS-el való illesztésekkel. A légijármű pilótakabinjának egység berendezését és a személyzetnek a GBAS-hez való kapcsolódását 5-számjegyes csatorna számok bevitelére lehet alapozni. Egy olyan illeszkedés, ami a megközelítés kiválasztáson és a repülés vezérlési funkción alapszik, és az ILS-nél fennálló jelenlegi gyakorlathoz hasonló, ugyancsak lehetséges. A GBAS csatorna számot tárolni lehet egy fedélzeti navigációs adatbázisban, egy megnevezett megközelítés egy részeként. A megközelítést a nevével lehet kiválasztani, és a csatorna számot automatikusan biztosítani lehet a berendezés részére, hogy annak ki 'kelljen' választani a megfelelő GBAS megközelítési adatokat a sugárzott adatokból. Hasonlóképpen a GBAS helymeghatározási szolgáltatás felhasználását is lehet egy 5-számjegyű csatorna szám kiválasztásra alapozni. Ez lehetővé teszi a Végső megközelítési szakasz /FAS/ adatok által meghatározott megközelítésektől eltérő üzemeltetések végrehajtását is.

7.7.2 A 20 001 és a 39 999 közötti csatorna számokból választanak egyet, amikor Végső Megközelítési Szakasz (FAS) adatot sugároznak ki a 4. Típusú közleményben. A 40 000 és a 99 999 közötti csatorna számokból választanak egyet, amikor a fedélzeti adatbázisból egy Megközelítés Függőleges Vezetéssel-hez (APV) kapcsolt FAS adathoz jutnak hozzá.

7.8 Referencia pálya adat-kiválasztó /RPDS/ és Referencia állomás adat-kiválasztó /RSDS/

Egy térképezési vázlat egy egyedi csatorna-szám kijelölést biztosít minden egyes GBAS megközelítésre. A csatorna-szám öt számjegyből áll, a 20 001-től a 39 999-ig terjedő tartományban. A csatorna-szám lehetővé teszi a GBAS légijármű fedélzeti al-rendszernek a pontos frekvenciára hangolást, és annak a Végső Megközelítési Szakasz (FAS) adatblokknak a kiválasztását, amely a kívánt megközelítést meghatározza. A pontos FAS adatblokk a referencia pálya adat-kiválasztóval (RPDS) kerül kiválasztásra, ami a 4. Típusú közleményben a FAS meghatározási adat egy részeként került beépítésre. A D-6. táblázat példákat mutat be a csatorna-szám, a frekvencia és az RPDS közötti összefüggésre. Ugyanilyen térképezési vázlatot kell alkalmazni a helymeghatározási szolgáltatásnak a Referencia állomás adat-kiválasztó /RSDS/ általi kiválasztására. Az RSDS a 2. Típusú közleményben

kerül sugárzásra, és lehetővé teszi egy olyan egyedüli GBAS földi al-rendszer kiválasztását, amely biztosítja a helymeghatározási szolgáltatást.
Az olyan földi al-rendszereknél, amelyek nem biztosítják a helymeghatározási szolgáltatást, de sugározzák a kiegészítő efemerisz adatokat, az RSDS a 255-re van kódolva. Az egy földi al-rendszer által sugárzott összes RPDS-nek és RSDS-nek egyedülinek kell lenni a sugárzási frekvencián a jel felhasználási földrajzi körzetén belül. Az RSDS értéke nem lehet azonos egyetlen sugárzott RPDS értékkel sem.

D-6. táblázat: Csatorna kijelölési példák

Csatorna-szám (N)	Frekvencia MHz-ben (F)	Referencia pálya adat- kiválasztó (RPDS), vagy Referencia állomás adat-kiválasztó (RSDS) szám
20 001	108,025	0
20 002	108,05	0
20 003	108,075	0
…..	…..	…..
20 397	117,925	0
20 398	117,95	0
20 412 (Megjegyzés)	108,025	1
20 413	108,05	1
…..	…..	…..

Megjegyzés. – A 20 398 és a 20 412 közötti csatornák nem oszthatók ki, mivel a csatorna algoritmusa olyan frekvenciákra jelöli ki azokat, amelyek kívül esnek a 108,025 MHz és a 117,950 MHz közötti tartományon. Hasonló csatorna kiosztási 'rés' fordul elő az egyes RPDS átmeneteknél is.

7.9 A Referencia Pálya Adat-kiválasztó /RPDS/ és a Referencia Állomás Adat-kiválasztó /RSDS/ kijelölése a szolgáltatás biztosítója által

Az RPDS és RSDS kijelöléseket ellenőrizni kell azért, hogy a csatorna számok duplikált használatát az adat sugárzó frekvencia védelmi területén belül elkerüljék. Ennek megfelelően a GBAS szolgáltatás biztosítónak biztosítania kell azt, hogy az RPDS és RSDS csak egyszer kerül kijelölésre egy meghatározott GBAS földi al-rendszer rádió hatótávolságán belül. Az RPDS és RSDS kijelölését a frekvencia kijelölésnek és a VHF adat sugárzás időréseinek kijelölésével együtt kell kezelni.

7.10 GBAS azonosító

A GBAS azonosító /ID/ használatos egy, a GBAS fedésterületi körzetén belüli egy adott frekvencián működő földi al-rendszer egyedülálló azonosítására. A légijármű navigálásakor egy GBAS földi al-rendszer egy, vagy több GBAS sugárzó állomásának adását fogja felhasználni (amiket a közös GBAS azonosító fog jellemezni).

7.11 Végső megközelítési szakasz (FAS) pálya

7.11.1 A FAS pálya egy térbeli vonal, amelyet a Leszállási küszöb pontja/Látszólagos küszöb pontja (LTP/FTP), a Repülési pálya irány pont (FPAP), a Küszöb keresztezési magasság (TCH) és a Siklópálya szöge (GPA) határozza meg. Ezek a paraméterek azokból az adatokból kerülnek meghatározásra, amelyeket a 4. Típusú közleményen belül a FAS adatblokk biztosít. Az ezen paraméterek és a FAS pálya közötti összefüggést a D-6. ábra mutatja be.

7.11.1.1 Az SBAS és néhány GBAS megközelítés számára szükséges FAS adatot a közös fedélzeti adatbázisban tárolják, mely támogatja mind az SBAS-t, mind a GBAS-t. Az Államok a felelősek az APV eljárások támogatásához szükséges FAS adat biztosításáért, amikor a 4. Típusú közleményt nem sugározzák ki. Ezek az adatok azokat a paramétereket tartalmazzák, melyek a FAS blokkban és az RSDS-ben vannak, valamint a kiosztott sugárzási frekvenciát is tartalmazzák. Egy adott megközelítési eljáráshoz szükséges FAS blokkot a
"B"- Függelék, 3.6.4.5.4 pontja és a B-66. Táblázat ismerteti.

7.11.2 *A Végső megközelítési szakasz /FAS/ pálya meghatározása*

7.11.2.1 *Oldalirányú irányítottság.* A Leszállási küszöb pont/Látszólagos küszöb pont /LTP/FTP/ jellemzően a futópálya küszöbénél, vagy annak közelében van. Azonban azért, hogy üzemeltetési körülmények, vagy fizikai korlátozások kielégítésre kerüljenek, az LTP/FTP lehet nem a futópálya küszöbénél is. A Repülési pálya irány pont /FPAP/ az LTP/FTP-hez kapcsolódóan használatos a megközelítés oldalirányú referencia síkjának meghatározására. Egy közvetlen egyenes megközelítésre, ami a futópályával egy vonalban van, a Repülési pálya irány pont /FPAP/ a futópálya megállási végénél, vagy azon túl van. Az FPAP nem kerül elhelyezésre a futópálya megközelítési vége elé.

7.11.2.2 *ΔHossz eltérés.* A Δhossz eltérés a futópálya végétől az FPAP-ig tartó távolságot határozza meg. Ez a paraméter azért van biztosítva, hogy lehetővé tegye a légijármű fedélzeti berendezése számára a futópálya végéig tartó távolság kiszámítását. Ha a Δhossz eltérés nincs beállítva úgy, hogy megfelelően jelezze a futópálya végét az FPAP-hoz viszonyítva, akkor a szolgáltatás biztosítónak biztosítania kell azt, hogy a paraméter „nincs biztosítva"-ként kerüljön kódolásra.

7.11.2.3 *Függőleges irányítottság.* A helyi függőleges a megközelítésre a WGS-84 ellipszoidra merőlegesként van meghatározva az LTP/FTP-nél, és ez jelentősen eltérhet a helyi gravitációs vektortól. A megközelítésre a helyi szint síkja úgy van meghatározva, hogy az az LTP/FTP-n áthaladó helyi függőlegesre merőleges sík (azaz az LTP/FTP-nél lévő ellipszoid érintője). Az Alapsík keresztezési pont (DCP) egy, a Küszöb keresztezési magasság /TCH/ által meghatározott pontnál lévő magasság az LTP/FTP felett. A Végső megközelítési szakasz /FAS/ pályája úgy van meghatározva, hogy egy vonal egy szögértékkel (amit a Siklópálya szöge /GPA/ határoz meg) ahhoz a helyi szintű síkhoz van viszonyítva, amely az Alapsík keresztezési ponton /DCP/ halad át. A Siklópálya befogási pont /GPIP/ az a pont, ahol a Végső megközelítési pálya keresztezi a helyi szint síkját. A GPIP ténylegesen – a futópálya görbületétől függően – lehet a futópálya felülete fölött, vagy előtt.

7.11.3 *„ILS-el hasonlónak látszó" eltérés számítások.* A jelenlegi légijármű tervezéshez való összeegyeztethetőségért a légijármű berendezései számára kívánatos az, hogy a kimenő vezetési információk a Végső megközelítési szakasz /FAS/ pályája által meghatározott megkívánt repülési pályához viszonyított eltérések formájában kerüljenek kiadásra.
A 4. Típusú közlemények tartalmazzák azokat a paramétereket, amelyek az ILS követelményekkel megegyező eltérések kiszámítását alátámasztják.

7.11.3.1 *Az oldalirányú eltérés meghatározása.* A D-6. ábra mutatja be a Repülési pálya irány pont /FPAP/ és az oldalirányú szög elétérések kiindulópontja közötti összefüggést. Az útirány szélesség paraméter és az FPAP használatos az oldalirányú eltérések kiindulópontjának és érzékenységének meghatározásához. Az FPAP elhelyezésének és az útirány szélesség értékének szabályozásával egy GBAS útirány szélességet és érzékenységet be lehet állítani a kívánt értékre. Ezeket be lehet állítani úgy, hogy egybeessenek egy meglévő ILS útirány szélességével és érzékenységével. Ez szükséges lehet, például, a meglévő látásos leszállási segédeszközökkel való összeegyeztethetőséghez.

7.11.3.1.1 *Az oldalirányú eltérés referenciája.* Az oldalirányú eltérés referencia síkja az a sík, ami magába foglalja az LTP/FTP-t, az FPAP-t és egy, a WGS-84 ellipszoidnak az LTP/FTP-nél lévő merőleges vektorát. Az egyenes-vonalú oldalirányú eltérés az a távolság, ami a számított légijármű helyzet az oldalirányú eltérés referencia síktól. A szögbeli oldalirányú eltérés a GBAS oldalszög referencia pontjához (GARP) viszonyított megfelelő oldalszög eltérés. A GARP az FPAP-on túl az eljárás középvonalában egy állandó 305 méteres
(1 000 láb) eltolású pontként került meghatározásra.

7.11.3.1.2 *Oldalirányú elmozdulási érzékenység.* Az oldalirányú elmozdulási érzékenységet a légijármű fedélzeti berendezése határozza meg a FAS adatblokkhoz megadott útirány szélességből. A szolgáltatás biztosítójának felelőssége az, hogy az útirány szélesség paramétert olyan értékre állítsa be, hogy az a teljes skálájú kitérésnek (azaz 0,155 Modulációs mélység különbség /DDM/, vagy 150 μA) megfelelő szöget adjon minden üzemeltetési kényszert figyelembe véve.

7.11.3.2 *Függőleges eltérések.* A függőleges eltéréseket a légijármű fedélzeti berendezése számítja ki egy GBAS magassági referencia ponthoz (GERP) vonatkoztatva. A GERP lehet a Siklópálya befogási pontnál /GPIP/, vagy a GPIP-től oldalirányban egy állandó GERP eltolási értékkel, 150 m-el eltoltan. Az eltolt GERP alkalmazása lehetővé teszi a siklópálya eltérésnél azt, hogy ugyanazt a hiperbolikus hatást hozza létre, mint ami az ILS, vagy MLS normál eltolási karakterisztikája (200 láb alatt). Annak az eldöntését, hogy a GERP eltolt vagy sem, a légijármű fedélzeti berendezés végzi a meglévő légijármű rendszerekkel kompatíbilis működési követelményekkel összhangban. A szolgáltatás biztosítóknak tudniuk kell azt, hogy a felhasználók kiszámíthatják a függőleges eltéréseket a GERP felhasználásával, amely bármelyik helyzetben van elhelyezve. A függőleges eltérések érzékenysége a légijármű fedélzeti berendezésben automatikusan van beállítva a Siklópálya szög /GPA/ egy funkciójaként. A GPA és a függőleges eltérés érzékenység közötti összefüggés megegyezik az ILS által biztosított siklópálya elmozdulási érzékenységgel.

7.11.4 *A futópálya középvonalával nem egy egyenesbe eső megközelítések.* Bizonyos üzemeltetések megkövetelhetik egy olyan megközelítési szakasz meghatározását, amely nem esik egy egyenesbe a futópálya középvonalával, ahogy azt a D-7. ábra bemutatja. Azokra a megközelítésekre, amelyek nem esnek egy egyenesbe a futópályával, az LTP/FTP lehet, hogy igen, lehet, hogy nem a futópálya meghosszabbított középvonalán van. Az ilyen típusú megközelítéseknél a Δhossz eltérésnek nincs jelentése és így „nem-biztosított”-ra kell állítani.

7.11.5 *SBAS szolgáltatás biztosító.* Egy közös formátum használatos a Végső megközelítési szakasz /FAS/ adatblokkban, amelyet mind a GBAS, mind az SBAS rendszernek fel kell használni. Az SBAS szolgáltatás biztosító azonosító /ID/ mező azt azonosítja, hogy melyik SBAS rendszer(eke)t használhatja az a repülőgép, amely a megközelítése során a FAS adatokat felhasználja. A GBAS szolgáltatás biztosító megakadályozhatja a bármelyik SBAS szolgáltatáshoz kapcsolódó FAS adatok felhasználását. A GBAS-en alapuló precíziós megközelítéseknél ez a mező nem használatos, és a légijármű fedélzeti GBAS berendezés szándékosan figyelmen kívül hagyhatja azt.

7.11.6 *Megközelítés azonosító.* A szolgáltatás biztosító felelős azért, hogy minden egyes megközelítésre kijelöljön egy megközelítés azonosítót. A megközelítés azonosításának egyedülállónak kell lenni egy nagy földrajzi területen belül. Az egy adott repülőtéren lévő több futópálya megközelítéseinek azonosítását úgy kell kiválasztani, hogy az összetévesztés és a téves azonosítás lehetőségét lecsökkentsék. A megközelítés azonosítását fel kell tűntetni azon a közzétett térképen, amely a megközelítést leírja.

7.12 Repülőtéri telepítési megfontolások

7.12.1 A GBAS földi al-rendszer telepítése különleges megfontolásokat foglal magába a referencia vevő antennák és a VHF adat sugárzó /VDB/ antenna(k) leendő elhelyezéseinek kiválasztásában. Az antenna elhelyezés tervezésénél az Annex 14 akadálykorlátozási követelményeit ki kell elégíteni.

7.12.2 *A referencia vevő antennák elhelyezése.* A helyszínt úgy kell kiválasztani, hogy az egy akadályoktól mentes terület legyen, úgy, hogy lehetővé tegye a műholdak jeleinek vételét olyan ’alacsony’ magassági szögben, amennyire az csak lehetséges. Általánosságban, ha bármi kitakarja a GNSS műholdakat az 5 foknál magasabb magassági szögekben, az csökkenteni fogja a rendszer rendelkezésre állását.

7.12.2.1 A referencia vevők antennáit úgy kell megtervezni és elhelyezni, hogy csökkentsék azokat a többutas szóródási jeleket, amelyek a megkívánt jelet zavarják. Az antennáknak a közel a földfelszín síkjához történő telepítése csökkenti az antenna reflexiókból eredő hosszú késleltetésű többutas szóródást. A felépítési magasságnak elegendőnek kell lenni ahhoz, hogy megelőzzék az antennák hóval való beborítását, vagy a karbantartó személyzet, illetve a földi forgalom általi interferenciát. Az antennát úgy kell elhelyezni, hogy bármilyen fém-szerkezet, mint például levegő szellőztetők, csövek és más antennák, az antenna közel-területi hatásain kívül legyenek.

7.12.2.2 Az egyes referencia vevő antenna elhelyezéseknél a több-utas visszaverődési hiba nagysága mellett a korrelációs fokot is számításba kell venni. A referencia vevő antennákat olyan helyeken kell elhelyezni, amelyek önálló többutas visszaverődési környezetet biztosítanak.

7.12.2.3 Az egyes antennák felszerelése magába kell foglaljon olyan felépítést, ami nem fog meghajolni a szél hatására, vagy jég terhelése alatt. A referencia vevő antennákat olyan területeken kell elhelyezni, ahol az átjárás ellenőrzött. A forgalom hozzájárulója lehet a többutas szóródás miatti hibának, vagy akadályozhatja az antennáktól a műholdra való rálátást.

7.12.3 *A VHF adat-sugárzó /VDB/ antenna elhelyezése.* A VDB antennát úgy kell elhelyezni, hogy egy akadálymentes rálátási vonal álljon fenn az antennától a fedésterület kiterjedésén belül minden alátámasztott Végső megközelítési szakasz /FAS/ pontra. Tekintetbe kell venni még a minimális adó-vevő elkülönítés biztosítását is, úgy, hogy a maximális térerősség ne kerüljön túllépésre. Abból a célból, hogy a szükséges fedés egy többszörös FAS-ra is biztosítva legyen egy adott repülőtéren, továbbá abból a célból, hogy a VDB antenna telepítési rugalmasságát lehetővé tegyék, az adó antenna körüli tényleges fedésterületi kiterjedésnél szükség lehet egy lényegesen nagyobb területre, mint ami egy egyedüli FAS részére szükséges. Ennek a fedésterület biztosításnak a képessége a VDB antenna helyének a futópályához viszonyított helyzetétől és a VDB antenna magasságától függ. Általánosságban mondva, megnövelt antenna magasságra lehet szükség a felhasználók részére az alacsony magasságokon a kielégítő jel erősség biztosításához, de ez elfogadhatatlan többutas szóródási nullát is eredményezhet a kívánt fedésterületi kiterjedésen belül. A megfelelő antenna magasságok meghatározását elemzésre alapozva kell meghozni annak biztosítása érdekében, hogy a jel erősség követelmények a teljes kiterjedésen belül kielégítésre kerüljenek. Figyelmet kell még fordítani a többutas szóródási környezetben lévő terep jellegzetességekre és épületekre is.

7.12.4 *Több adó antenna felhasználása a VDB fedésterületének javítása céljából.* Néhány GBAS berendezés telepítésnél korlátozások állnak fenn az antenna elhelyezésnél, a helyi terep, vagy akadályok földi többutas szóródást és/vagy jel-blokkolást eredményezhetnek úgy, hogy bonyolulttá teszik az előírt térerősség biztosítását a fedésterület terjedelmén belüli minden ponton. Néhány GBAS földi berendezésnél alkalmazni lehet egy, vagy több kiegészítő antenna rendszert úgy telepítve, hogy olyan diverziti jel-utat biztosítsanak, ami által azok közösen megfeleljenek a fedésterületi követelményeknek.

7.12.4.1 Amikor többszörös antenna rendszerek használatosak, akkor az antenna sorrendet és a közlemény ütemezést úgy kell elrendezni, hogy a fedésterületen belül minden pontban olyan sugárzást biztosítson, ami következetesen betartja az előírt minimális és maximális adat sugárzási átviteli sebességet és térerőt, anélkül, hogy meghaladná a vevő alkalmazkodási képességét az adásról adásra történő jelerősség változásokban egy adott időrésben. A vevőnek az elveszett, vagy duplikált közleményeket érintő feldolgozási kérdéseinek elkerülése céljából egy egyedüli kereten belül lévő adott mérési típusú – az 1. Típusú közlemények, vagy az összekapcsolt 1. Típusú közlemény-párok – összes adat továbbítását azonos adat-tartalommal kell biztosítani.

7.12.4.2 Egy példa a többszörös antennák használatára, amikor két, ugyanazon helyen telepített, de a föld felszíne felett különböző magasságban elhelyezett antennát használnak egy berendezésnél. Az antennák magassága úgy van megválasztva, hogy az egyik antenna karakterisztikája kitölti a másik antenna karakterisztikájában a földfelszín síkja által eredményezett reflexiók miatt létrejövő nullákat. A földi állomás váltogatja a sugárzást a két antenna között, az egyes keretek egy, vagy két kijelölt időrését használva az egyes antennákra. Az 1. Típusú közlemények keretenként egyszer kerülnek sugárzásra antennánként. Ez lehetővé teszi egy, vagy két 1. Típusú közlemény vételét keretenként, attól függően, hogy vajon a felhasználó egy antenna karakterisztika ’nulláján’ belül tartózkodik-e. A 2. és 4. Típusú közlemények az első antennáról egy keretben kerülnek sugárzásra, azután a második antennáról a következő keretben. Ez lehetővé teszi minden 2. és 4. Típusú közlemény egyikének vételét egy, vagy két keretben a felhasználó helyzetétől függően.

7.13 Az oldalirányú és a függőleges riasztási határértékek meghatározása

7.13.1 Az oldalirányú és a függőleges riasztási határértékek az I. Kategóriájú precíziós megközelítésekre vonatkozóan úgy kerülnek kiszámításra, ahogy az a ”B”- Függelék B-68. és B-69. táblázataiban meghatározásra került. Ezekben a számításokban a D és H paramétereknek a jelentése a D-8. ábrán került bemutatásra.

7.13.2 Az 1. Kategóriájú precíziós megközelítésekre vonatkozó függőleges riasztási határérték léptéke a Leszállási küszöb pontja/Látszólagos küszöb pontja (LTP/FTP) felett 60m (200 láb) magasságtól kezdődik. Egy olyan eljárásnál, ahol a döntési magasság több, mint 60m (200 láb), a VAL azon a döntési magasságon nagyobb lesz, mint a kisugárzási FASVAL.

7.13.3 Az oldalirányú és a függőleges riasztási határértékek a 40 000 és 99 999 közötti csatorna számokhoz kapcsolódó APV eljárásokra vonatkozóan ugyanúgy kerülnek kiszámításra, ahogy az SBAS-t használó APV eljárásoknál történnek, amit a ”D”- Melléklet, 3.2.8 pontja tartalmaz.

7.14 Ellenőrző és karbantartó tevékenységek

7.14.1 Speciális ellenőrzési követelményekre, vagy beépített vizsgálatokra lehet szükség, és ilyeneket kell meghatározni egyedileg az Államoknak. Mivel a VHF adat sugárzás /VDB/ jelei a kritikusak a GBAS földi állomások üzemeltetésénél, a VDB bármilyen hibáját, - azaz hogy sikeresen továbbítsa a felhasználható jeleket a kijelölt időréseken belül és a teljes fedésterületi körzeten belül - amint csak lehetséges, ki kell javítani. Ennek megfelelően ajánlott az, hogy irányvonalként a következő feltételeket alkalmazzák a VDB ellenőrző berendezés kivitelezésénél:

a) Teljesítmény. Egy jelentékeny teljesítmény csökkenést 3 másodpercen belül észlelni kell.

b) Közlemény típus elvesztése. Bármelyik beütemezett közlemény típus(ok) továbbításának hibája. Ezt arra a hibára lehet alapozni, hogy egy egyedüli közlemény típusnak az egymás utáni sorrendben, vagy a különféle közlemény típusok egy kombinációjának a továbbítása hiányzik.

c) Az összes közlemény típus elvesztése. Bármelyik közlemény típus továbbításának 3 másodperccel egyenlő, vagy annál hosszabb idejű hibáját észlelni kell.

7.14.2 Egy hiba észlelésekor és egy második adó hiányában a VDB szolgáltatás befejezését kell számításba venni, ha a jelet nem lehet megbízhatóan felhasználni a fedésterületen belül, oly mértékig, hogy az a légijárművek üzemeltetését jelentős mértékben befolyásolná. Az üzemeltetési eljárásokban megfelelő tevékenységeket kell figyelembe venni annak az esetnek az enyhítésére, ha a jel a szolgáltatásból eltávolításra kerül. Ez magában foglalhatja a diszpécser szolgálat karbantartó specialistái általi GBAS VDB javítását, vagy különleges ATC eljárásokat. Kiegészítőleg, karbantartási tevékenységet kell végrehajtani, amikor lehetséges, az összes beépített vizsgálati észlelésű hibák esetében a GBAS szolgáltatás elvesztésének megelőzése érdekében.

7.15 Példák a VHF adat sugárzási /VDB/ közleményekre

7.15.1 A VDB közlemények kódolására példák találhatók a D-7.-től a D-10.-ig terjedő táblázatokban. A példák bemutatják a különféle alkalmazási paraméterek kódolását, beleértve a Ciklikus Redundancia Ellenőrzést (CRC) és a Vevő oldali hibajavítás (FEC) paramétereit, valamint a bit ’rejtjelezés’ és a D8PSK szimbólum kódolás eredményeit. A közlemény paraméterek műszaki értékei ezekben a táblázatokban a közlemény kódolási folyamatot mutatják be, és nem szükségszerűen a tényleges értékek képviselői.

7.15.2 A D-7. táblázat egy példát ad az 1. Típusú VDB küldeményre. A kiegészítő közlemény jelzés mező annak jelzésére került kódolásra, hogy ez a két 1. Típusú közleményből az első, amit ugyanazon a kereten belül továbbítani kell. Ez bemutatás céljából került ide; a második 1. Típusú közlemény nem jellemzően szükséges, kivéve, hogy több távolság-mérési forrás helyesbítés sugárzását teszi lehetővé annál, mint amit egy egyedüli közlemény be tud fogadni.

7.15.3 A D-7A. táblázat egy példát ad a 101. Típusú VDB küldeményre. A kiegészítő közlemény jelzés mező annak jelzésére került kódolásra, hogy ez a két 101. Típusú közleményből az első, amit ugyanazon a kereten belül továbbítani kell. Ez bemutatás céljából került ide; a második 101. Típusú közlemény nem jellemzően szükséges, kivéve, hogy több távolság-mérési forrás helyesbítés sugárzását teszi lehetővé annál, mint amit egy egyedüli közlemény be tud fogadni.

7.15.4 A D-8. táblázat példákat ad arra, amikor egy 1. Típusú VDB közlemény és egy 2. Típusú VDB közlemény egy egyedül álló szinkron vezérjel után van kódolva (azaz két közlemény kerül sugárzásra egy egyedüli adattovábbítási időrésben). Az 1. Típusú közlemény kiegészítő közlemény jelzés mezője azért van kódolva, hogy jelezze azt, miszerint ez két 1. Típusú közleményből a második, amit ugyanazon a kereten belül továbbítani kell. A 2. Típusú közlemény magába foglalja az 1. kiegészítő adatblokkot. A D-8A. Táblázat példát mutat arra, amikor az 1. Típusú és a 2. Típusú közlemények kiegészítő 1. és 2. adatblokkal rendelkeznek.

7.15.5 A D-9. táblázat egy példát mutat be a 4. Típusú két Végső megközelítési szakasz /FAS/ adatblokkot magába foglaló közleményre.

7.15.6 A D-10. táblázat egy példát ad az 5. Típusú közleményre. Ebben a példában a jelforrás rendelkezésre állási időtartamok az összes megközelítésre és két távolság-meghatározási jelforrásra vannak biztosítva. Kiegészítőleg, a jelforrás rendelkezésre állási időtartamok két egyedi megközelítésre vannak biztosítva: az első megközelítésnek két befogott távolság-meghatározási forrása van és a második megközelítés egy befogott távolság-meghatározási forrással rendelkezik. A 2. Típusú közlemény tartalmaz kiegészítő 1. adatblokkot.

7.16 GBAS felmérési pontosság

A navigációs berendezések felmérési pontosságának szabványait az Annex 14 – *Repülőterek* foglalja magába. Ezenkívül a *Geodéziai Világrendszer-1984*. (WGS-84) (Doc 9674) *Kézikönyv* ad útmutatásokat az egyes repülőtereken lévő felmérési ellenőrző pontok hálózatának létesítéséről és arról, hogy a hálózatot hogyan kell a WGS-84 koordináták megállapítására felhasználni. Addig, amíg a GBAS-re speciális követelmények nem kerülnek kidolgozásra, az Annex 14-ben lévő, a repülőtéren elhelyezett navigációs berendezések felmérési pontosságára vonatkozó követelményeket kell alkalmazni.

A ”B”- Függelékben lévő, a 3.fejezet 3.6.7.2.3.4 pontban leírt ajánlások a GBAS referencia pontjának felmérési pontjára vonatkozóan azt célozzák, hogy tovább csökkenjen a hiba - a WGS-84 helymeghatározásban a levegőben lévő a GBAS helymeghatározási szolgáltatást felhasználó számára – egy olyan értékre, ami kisebb annál, mint amit a ”B”- Függelék 3. fejezete 3.6.7.2.4.1 és 3.6.7.2.4.2 pontjai követelményként megállapítanak a GBAS szabványokban és hogy tovább növelje a felmérési pontosságot ahhoz hasonlítva, ami az Annex 14-ben előírásra került. A GBAS-ben használt összes légiforgalmi adat sértetlensége megegyezik a 3. fejezet 3.7.2.4-1. táblázatában leírt sértetlenségi követelményekkel.

7.17 2. Típusú közlemény kiegészítő 2. adatblokk

A 2. Típusú közlemény kiegészítő 2. adatblokk felhasználható a GRAS-nál, azért hogy lehetővé tegye, hogy a GRAS fedélzeti al-rendszer a GBAS sugárzó állomások között kapcsolhasson, különösen akkor, ha a GBAS sugárzó állomások eltérő frekvenciákat használnak. A kiegészítő 2. adatblokk az éppen vett GBAS sugárzó állomás és a többi szomszédos, vagy közeli GBAS sugárzó állomás csatorna számát és helyét azonosítja.

MEGJEGYZÉSEK. –

1. A jobbról a legszélső bit a legkisebb helyértékű bitje /LSB/ a bináris paraméter értéknek, és ez az első bit, ami továbbításra, vagy a bit-keverőbe kerül küldésre. Az összes adatmező a táblázatban meghatározott sorrendben kerül leadásra.

2. Ez a mező hexadecimálisan van kódolva, és az első bitjével kerül a bit-keverőbe továbbításra, mint a legnagyobb helyértékű bit /MSB/. Az első karakter egy egyedülálló bitet képvisel.

3. Ebben a példában a kitöltő bitek nincsenek keverve.

4. Ez a mező képviseli a fázist, a $\pi/4$ egységben (például egy 5-ös érték egy $5\pi/4$ radián fázist képvisel) az első szimbólum fázisára vonatkoztatottan.

MEGJEGYZÉSEK. –

1. A jobbról a legszélső bit a legkisebb helyértékű bitje /LSB/ a bináris paraméter értéknek, és ez az első bit, ami továbbításra, vagy a bit-keverőbe kerül küldésre. Az összes adatmező a táblázatban meghatározott sorrendben kerül leadásra.

2. Ez a mező hexadecimálisan van kódolva, és az első bitjével kerül a bit-keverőbe továbbításra, mint a legnagyobb helyértékű bit /MSB/. Az első karakter egy egyedülálló bitet képvisel.

3. Ebben a példában a kitöltő bitek nincsenek keverve.

4. Ez a mező képviseli a fázist, a π/4 egységben (például egy 5-ös érték egy 5π/4 radián fázist képvisel) az első szimbólum fázisára vonatkoztatottan.

D-8. táblázat: Példa egy egyedül álló jelsorozatban továbbított

1. Típusú és 2. Típusú VHF adat sugárzási /VDB/ közleményekre

MEGJEGYZÉSEK. –

A jobbról a legszélsõ bit a legkisebb helyértékû bitje /LSB/ a bináris paraméter értéknek, és ez az elsõ bit, ami továbbításra, vagy a bit-keverõbe kerül küldésre. Az összes adatmezõ a táblázatban meghatározott sorrendben kerül leadásra.

1. Ez a mező hexadecimálisan van kódolva, és az első bitjével kerül a bit-keverőbe továbbításra, mint a legnagyobb helyértékű bit /MSB/. Az első karakter egy egyedülálló bitet képvisel.

2. Ebben a példában a kitöltő bitek nincsenek keverve.

3. Ez a mező képviseli a fázist, a π/4 egységben (például egy 5-ös érték egy 5π/4 radián fázist képvisel) az első szimbólum fázisára vonatkoztatottan.

MEGJEGYZÉSEK. –

1. A jobbról a legszélső bit a legkisebb helyértékű bitje /LSB/ a bináris paraméter értéknek, és ez az első bit, ami továbbításra, vagy a bit-keverőbe kerül küldésre. Az összes adatmező a táblázatban meghatározott sorrendben kerül leadásra.

2. Ez a mező hexadecimálisan van kódolva, és az első bitjével kerül a bit-keverőbe továbbításra, mint a legnagyobb helyértékű bit /MSB/. Az első karakter egy egyedülálló bitet képvisel.

3. A szimbólumokat a közlemény első szimbólumához viszonyított differenciál fázisuk ábrázolja, $\pi/4$ egységben (például egy 5-ös érték egy $5\pi/4$ radiáns fázist képvisel) az első szimbólum fázisára vonatkoztatottan.

7.18 101. Típusú közlemény

A 101. Típusú közlemény az 1. Típusú közlemény alternatívája, amit azért fejlesztettek ki, hogy megfeleljen a GRAS rendszerek speciális szükségleteinek. A két közlemény típus tartalma és alkalmazása közötti elsődleges különbség kettős: a) a 101. Típusú közleménynek nagyobb a σ_{pr_gnd} értéktartománya és b) a földi rendszer idő-a-risztásig ideje nagyobb a rendszer sugárzó 101. Típusú közlemények számára. Egy rendszerben az első állapot tipikusan ott fordul elő, ahol egy sugárzó állomás nagy területet fed le, így a dekorrelációs hibák megnövelik a pszeudó-távolság korrekciós hibák felső határértékét. A második állapot olyan rendszerekre jellemző, ahol a központi mester állomás egy nagy területet lefedő több vevőről érkező jeleket dolgoz fel.

8. A Jel minőség ellenőrzés (SQM) tervezés

8.1 A Jel minőség ellenőrzés (SQM) célja az, hogy észlelje a műhold jel rendellenességeket annak érdekében, hogy megelőzze azt, hogy a légijármű fedélzeti vevők félrevezető információkat (MI) használjanak fel. A félrevezető információ /MI/ egy nem-észlelt légijármű fedélzeti pszeudo-távolság differenciál hiba, amely nagyobb annál a maximális hibánál (MERR), amit el lehet tűrni. Ezek a nagy pszeudo-távolság hibák a műhold ’hasznos terhelési’ jellemzői által okozott torzított /durva/ hozzáférési /C/A/ kód korrelációs csúcs torzítása miatt vannak. Ha a referencia vevő úgy van használva, hogy létrehozza a differenciál helyesbítéseket, és a légijármű fedélzeti vevőjének van eltérés mérő mechanizmusa (azaz vevő sávszélesség és követő kör korrelátor szünet), akkor a jel-torzítás különböző módon érinti azokat. A Jel minőség ellenőrzésnek /SQM/ védenie kell a légijármű fedélzeti vevőjét azokban az esetekben, amikor a mechanizálás nem azonos. Az SQM teljesítményének további meghatározója a műhold hiba érzékelésének valószínűsége és a műhold hiba helytelen jelentésének valószínűsége.

8.2 Azokat a jel hatásokat, amik létrehozhatják azt, hogy egy Föld Bázisú Kiegészítő Rendszer /GBAS/, vagy Műhold Bázisú Kiegészítő Rendszer /SBAS/ egy félrevezető információt adjon le, három különböző hatásként kategorizálhatók a korrelációs funkcióra, a következők szerint:

a) Holt zónák: Amikor a korrelációs funkció elveszti a csúcsát, akkor a vevők diszkriminátor funkciója egy ’lapos pontot’, vagy holt zónát fog magába foglalni. Ha a referencia vevő és a légijármű fedélzeti vevője ennek a holt zónának különböző részeit rögzíti, akkor az félrevezető információt /MI/ eredményezhet.

b) Hamis csúcsok: Ha a referencia vevő és a légijármű fedélzeti vevő különböző csúcsokat rögzít, akkor az MI-t eredményezhet.

c) Torzítások: Ha a korrelációs csúcs eltorzult, és egy légijármű más korrelátor szünetet használ ahhoz képest, mint amit a referencia vevők alkalmaznak, akkor félrevezető információ /MI/ tapasztalható.

8.3 Fenyegetés modell alkalmazása javasolt a Jel minőség ellenőrzés /SQM/ kiértékelésének három részére, ami létrehozhatja a fentiekben felsorolt három korrelációs csúcs ’kórképet’.

8.4 Az ’A’ fenyegetés modell egy szabvány torzított hozzáférési /C/A/ kódot foglal magában, kivéve azt, hogy a pozitív chipeknek egy olyan lefutó éle van, ami annak a chipnek a pontos vég-idejéhez viszonyítva siet, vagy késik. Ez a fenyegetés modell a Navigációs adat egységben (NDU) kapcsolódik a hibához, a GPS, vagy GLONASS műhold digitális szegmensében.

8.4.1 Az ’A’ fenyegetés modellnek egy GPS-re egy egyedüli paramétere van, a Δ, ami a sietés ($\Delta < 0$), vagy a késés ($\Delta > 0$) a chip tört részében kifejezve. Ennek a paraméternek a tartománya $-0{,}12 \leq \Delta \leq 0{,}12$. A GLONASS-ra a egy egyedüli paraméter van, a Δ, ami a sietés ($\Delta < 0$), vagy a késés ($\Delta > 0$) a chip tört részében kifejezve. Ennek a paraméternek a tartománya $-0{,}11 \leq \Delta \leq 0{,}11$.

8.4.2 Ezen a tartományon belül az ’A’ fenyegetés modell létrehozza a fentiekben leírt holt zónákat. (A sietéses hullámformát nem kell ellenőrizni, mivel azok korrelációs funkciója egyszerűen előreviszi a korrelációs funkciót a késésre; ennélfogva a félrevezető információ /MI/ fenyegetés egyforma.)

8.5 A ’B’ fenyegetés modell bevezeti az amplitúdó-modulációt és a teljesítőképesség csökkenést a GPS, vagy GLONASS műhold analóg részében. Meghatározottabban, az egy másodrendű rendszer kimenetéből áll akkor, amikor a névleges C/A kód alapsáv jele a bemenet. A ’B’ fenyegetés modell elfogadja azt, hogy a teljesítőképesség csökkent műhold al-rendszert egy lineáris rendszerként be lehet vinni egy komplex konjugált pólus-pár által. Ezek a pólusok a $\sigma \pm j2\pi f_d$-nél vannak, ahol a ’σ’ a csillapító tényező neper/másodperc; és az ’f_d’ a rezonancia frekvencia ciklus/másodperc egységekben.

8.5.1 Egy másodrendű rendszer egység ugrásra adott válaszát a következő adja:

$$e(t) = \begin{cases} 0 & t \le 0 \\ 1 - \exp(-\sigma t)\left[\cos\omega_d t + \dfrac{\sigma}{\omega_d}\sin\omega_d t\right] & t \ge 0 \end{cases}$$

ahol a $\omega_d = 2\pi f_d$.

8.5.2 A ’B’ fenyegetés modell a GPS-re a másodrendű rendellenességeknek megfelelően a Δ, f_d és σ paraméterekre a következő tartományokat használja fel:

$$\Delta = 0;\ 4 \le f_d \le 17;\quad \text{és}\quad 0{,}8 \le \sigma \le 8{,}8.$$

A ’B’ fenyegetés modell a GLONASS-ra a másodrendű rendellenességeknek megfelelően a Δ-ra a következő paraméter tartományokat használja fel:

$$\Delta = 0;\ 10 \le f_d \le 20;\quad \text{és}\quad 2 \le \sigma \le 8.$$

8.5.3 Ezeken a paraméter tartományokon belül a ’B’ fenyegetés modell létrehozza a korrelációs csúcs torzításokat, valamint a hamis csúcsokat.

8.6 A ’C’ fenyegetés modell mindkettőt, a sietés/késés-t és az amplitúdó-modulációt is bevezeti. Kifejezetten, ez a másodrendű rendszerből eredő kimenetekből áll akkor, amikor a C/A kód jel a bemenetnél sietést, vagy késést szenved el. A hullámforma a fentiekben leírt két hatás kombinációja.

8.6.1 A ’C’ fenyegetés modell a GPS-re a Δ-ra, f_d-re és σ-ra a következő paraméter tartományokat használja fel:

$$-0{,}12 \le \Delta \le 0{,}12;\ 7{,}3 \le f_d \le 13;\quad \text{és}\quad 0{,}8 \le \sigma \le 8{,}8.$$

A ’C’ fenyegetés modell a GLONASS-ra a Δ-ra, f_d-re és σ-ra a következő paraméter tartományokat használja fel:

$$-0{,}11 \le \Delta \le 0{,}11;\ 10 \le f_d \le 20;\quad \text{és}\quad 2 \le \sigma \le 8.$$

8.6.2 Ezen paraméter tartományokon belül a ’C’ modell létrehoz holt zónákat, korrelációs csúcs torzításokat és hamis csúcsokat.

8.7 A GPS-től és a GLONASS-tól eltérően a Műhold Bázisú Kiegészítő Rendszer /SBAS/ jelet a szolgáltatás biztosító helyezi üzembe és ellenőrzi. Ezen felül a szolgáltatás biztosító folyamatosan ellenőrzi az SBAS-ból jövő jelek minőségét. Ebből a célból egy fenyegetés modell kerül meghatározásra és közzétételre a szolgáltatás biztosító által az egyes SBAS műholdakra. Az SBAS jel minőség ellenőrzés /SQM/ úgy lesz megtervezve, hogy az összes, a D-12. táblázatban leírtaknak megfelelő repülési elektronikát védje. A Fenyegetés modell közzététele azokra az esetekre szükséges, ahol a szolgáltatás biztosító lehetővé teszi azt, hogy a szomszédos szolgáltatás biztosítótól eredő SBAS távolság-meghatározási jelek felhasználásra kerüljenek a precíziós megközelítések számára az SBAS, vagy GBAS által. Ezekben az esetekben a szolgáltatás biztosító folyamatosan ellenőrizni fogja a szomszédos műholdtól eredő SBAS távolság-meghatározási jelet.

8.8 Abból a célból, hogy egy meghatározott folyamatos ellenőrző rendszer teljesítményét ellenőrizzék, az ellenőrző berendezés határértékeit úgy kell meghatározni és beállítani, hogy védje az egyedi műholdak pszeudo-távolság hibáit, a védelmi szintre vonatkozóan a földi al-rendszerek teljességi kockázatának felhasználásával. A Maximális eltűrhető hibát (MERR-ként jelezve) az egyes 'i' távolság-meghatározási forrásokban a Földi Bázisú Kiegészítő Rendszer /GBAS/-ben lehet meghatározni, mint:

$MERR = K_{ffmd}\sigma_{pr\_ground,i}$ és

$$MERR = K_{V,PA}\sqrt{\sigma^2_{i,UDRE} + \min\left\{\sigma^2_{i,UIRE}\right\}}$$

Az SBAS megközelítés függőleges vezetéssel /APV/ és precíziós megközelítésekre, ahol a $\min\left\{\sigma^2_{i,UIRE}\right\}$ minimális lehetséges érték valamennyi felhasználó részére. A MERR a hibamentes felhasználói vevő kimeneten kerül kiértékelésre, és a műhold magassági szögétől és a földi rendszer teljesítményétől függően változó.

8.9 A Jel minőség ellenőrzés /SQM/ úgy van megtervezve, hogy a Felhasználói differenciális távolságmérési hibát /UDRE/ olyan értékre korlátozza, ami a MERR alatt van egy műhold rendellenesség esetében. Jellemzően az SQM méri a különféle korrelációs csúcs értékeket és olyan 'jelközöket' és arány metrikát hoz létre, amelyek leírják a korrelációs csúcs torzításokat. A D-9. ábra mutatja be egy hibamentes, szűrés nélküli korrelációs csúcs tetejének jellemző pontjait.

8.9.1 Egy korrelátor pár használatos a nyomkövetéshez. Az összes egyéb korrelátor érték ehhez a korrelátor párhoz viszonyítottan kerül mérésre.

8.9.2 Az ellenőrző metrika két típusa van kialakítva: a korai– mínusz–késői metrika (D), amelyek a csúcs torzítások által okozott nyomkövetési hibákra utalnak, és az amplitúdó viszony metrika (R), amellyel a meredekséget mérik és az /amplitúdó/ csúcs egyenletesség, vagy a közel többszörös csúcsokra utalnak.

8.9.3 Szükséges az, hogy a Jel minőség ellenőrzés /SQM/ vevő rendelkezzen egy olyan előkorrelációs sávszélességgel, ami megfelelően széles ahhoz, hogy mérje a keskeny térköz metrikát, úgy, hogy az ne okozzon maga is jelentős csúcs-torzítást vagy, hogy eltakarja azokat a rendellenességeket, amelyeket a műholdak hibái okoztak. Jellemzően, az SQM vevőnek a GPS-re legalább 16 MHz-es és a GLONASS-ra legalább 15 MHz-es előkorrelációs sávszélességgel kell rendelkezni.

8.9.4 Az ellenőrző metrika ezután alul-áteresztő digitális szűrőkkel kerül simításra. Ezeknek a szűrőknek az idő-állandója rövidebb annál, mint amit kapcsoltan (és 100 másodpercre szabványosítottan) a referencia vevők alkalmaznak a differenciál helyesbítések származtatására és a légijármű fedélzeti vevők a pszeudo-távolság mérések simításához (vivőhullám simításra felhasználva). A simított metrika kerül ezután a küszöbökkel összehasonlításra. Ha a küszöbök bármelyike túllépésre kerül, akkor egy riasztás jelentkezik arra a műholdra.

8.9.5 A küszöbök használatosak azoknak a teljesítményeknek a származtatására, amelyek Minimális észlelhető hibák-ként (MDE-k) és Minimális észlelhető arányok-ként (MDR-ek) kerülnek meghatározásra. A hibamentes adás hibás észlelésének valószínűsége és a kimaradt észlelés valószínűsége használatos az MDE-k és MDR-ek származtatására. A (D) és (R) metrika zaj $\sigma_{D,test}$-ként és $\sigma_{R,test}$-ként jelölve – az alábbiakban – uralja a többutas visszaverődési hibákat. Jegyezzék meg, hogy a metrika ellenőrzéseknek is lehet egy középértéke (μ_{test}), amit az SQM vevő szűrőjének torzítása okoz. A küszöb ellenőrzéseket is számításba kell venni a középértékeknél.

8.9.6 Azok az MDE és MDR értékek, amelyek a Jel minőség ellenőrzés /SQM/ teljesítmény szimulációkban használatosak, a következő egyenletekre alapozva kerültek kiszámításra:

$$MDE = (K_{ffd} + K_{md})\ \sigma_{D,test} \text{ és}$$
$$MDR = (K_{ffd} + K_{md})\ \sigma_{R,test}$$

ahol:

K_{ffd} = 5,26 Ami a jellemző hibamentes érzékelés szorzója egy $1{,}5 \times 10^{-7}$ ellenőrzésenkénti hibás érzékelési valószínűséget képvisel;

K_{md} = 3,09 Ami a jellemző kimaradt észlelés szorzója egy 10^{-3} ellenőrzésenkénti kimaradt észlelési valószínűséget képvisel;

$\sigma_{D,test}$ Az eltérési ellenőrzés metrika ’D’ mért értékeinek szabvány eltérése; és

$\sigma_{R,test}$ Az arány ellenőrzés metrika ’R’ mért értékeinek szabvány eltérése.

8.9.7 Ha reflexió független SQM vevők használatosak a hibák érzékeléséhez, akkor a szigma értékeket le lehet csökkenteni a független ellenőrző berendezések számának négyzetgyökével.

8.9.8 Hiba akkor kerül bejelentésre, ha

$$|\ D,test - \mu_{D,test}\ | \geq MDE, \text{ vagy}$$
$$|\ R,test - \mu_{R,test}\ | \geq MDR$$

bármelyik elvégzett ellenőrzésre, ahol a $\mu_{X,test}$ az ’X’ ellenőrzés középértéke hibamentes SQM vevő szűrő torzításra visszavezetve, valamint hogy a korrelációs csúcs torzítás sajátosan jellemző az egyedi C/A kód Ál-véletlen zajára /PRN/. (A C/A kódok korrelációs csúcsai nem mindegyikének azonos a meredeksége. A szimulációs környezetben azonban ezt a PRN torzítást figyelmen kívül lehet hagyni, és pontos korrelációs csúcsot lehet használni, eltekintve a szimulált szűrő torzítástól.)

8.10 Az ellenőrzési statisztika szabvány eltéréseit $\sigma_{D,test}$ -ként és $\sigma_{R,test}$ -ként az adatgyűjtésen keresztül lehet meghatározni egy több-kollerátorú vevőn a várható üzemeltetési környezetben. Az adatgyűjtő vevő a korrelátorok egy egyszerű nyomkövető párját használja fel és kiegészítő korreláció funkció mérési pontokat, amelyek ehhez a nyomkövető párhoz vannak kapcsolva, ahogy az a D-9. ábrán bemutatásra kerül. Az adatok az összes rendelkezésre álló mérési pontra összegyűjtésre és simításra kerülnek abból a célból, hogy a metrikájuk kiszámításra kerüljön. Ezeknek a metrikáknak a szabvány eltérése határozza meg $\sigma_{D,test}$ -et. Az is lehetséges, hogy ezeket az egy szigma ellenőrző statisztikákat kiszámítják, ha a telepítési környezet többutas visszaverődési modellje rendelkezésre áll.

8.10.1 Az eredményként kapott $\sigma_{D,test}$ nagymértékben függő attól a többutas szóródási környezettől, amelyben az adatok összegyűjtésre kerültek. A többutas szóródás miatti eltérés egy nagyságrenddel nagyobb lehet annál, mint amit a zaj eredményezhet még a minimális vivőfrekvencia zaj szintnél is.

Ez a helyzet magyarázza meg az antenna tervezés és a telepítési követelmények fontosságát, amelyek elsődleges tényezők annak a többutas szóródási szintnek a meghatározásában, ami a vevőbe be fog lépni. A többutas szóródás csökkenése jelentős mértékben le fogja csökkenteni a létrejövő Minimális észlelhető hibát /MDE/ és ezáltal növeli a Jel minőség ellenőrzés /SQM/ teljesítőképességét.

8.10.2 A $\mu_{D,test}$ és a $\mu_{R,test}$ középértékei másrészről egy viszonylag hibamentes környezetben kerültek meghatározásra, úgy mint egy GPS és GLONASS jel szimulátor bemenetként való felhasználásán keresztül. Ezek a középértékek a névleges Jel minőség ellenőrzési /SQM/ vevők autokorrelációs csúcsainak szűrő torzítását modellezik, beleértve a szomszédos mellék autokorrelációs csúcsok miatti torzítási hatásokat. A közepes értékek eltérhetnek az ezekre a jellemzőkre alapozott különféle Ál-véletlen zajokra.

8.11 A földi ellenőrző berendezésnél abból a célból, hogy a felhasználókat a fentiekben leírt különféle fenyegetés modellek ellen megvédjék, az szükséges, hogy elfogadjuk, hogy a légijármű fedélzeti vevőknek speciális karakterisztikája van. Ha az ilyen korlátozás nem kerülne elfogadásra, akkor a földi ellenőrző berendezés komplexitása szükségtelenül túl magas lenne. A technológia fejlődése a légijármű fedélzeti vevőkben megnövelt észlelési képességhez vezethet, és csökkentheti a jelenlegi kényszert.

8.11.1 A kettős delta-korrelátoroknál a légijármű fedélzeti vevője a legerősebb korrelációs csúcsot követi a teljes kódsorozat során a navigációs megoldásban használt minden egyes távolság-meghatározási forrásra.

8.11.2 A kettős delta-korrelátoroknál az elő-korrelátor szűrő legalább oktávonként 30 dB-el ’előre gördül’ az átváltási sávban.

8.11.3 A következő paraméterek használatosak a követési teljesítmény adatok leírására a műholdak egyes típusára:

a) A pillanatnyi korrelátor térköz úgy van meghatározva, hogy az a korrelációs funkció korai és késői mintái egy egyedi sorozat közötti térköz;

b) Egy átlagos korrelátor térköz úgy van meghatározva, hogy az a pillantnyi korrelátor térköz egy egy-másodperces átlaga. Az átlag minden egyes egy-másodperces időkeretre vonatkozik;

c) A diszkriminátor Δ a korai-mínusz-késői minták egy átlagán alapszik a meghatározott tartományon belüli térközökkel, vagy a $\Delta = = 2\Delta_{d1} - \Delta_{2d1}$ típusú mindkét értékre, a d_1-re és a $2d_1$-re a meghatározott tartományban. Akár koherens, vagy nem-koherens diszkriminátor használatos;

d) A differenciál csoport-futási időt kell alkalmazni a teljes légijármű fedélzeti rendszerre a korrelátort megelőzően, az antennát is beleértve. A differenciál csoport-futási idő a következők szerint van meghatározva:

$$\left|\frac{d\phi}{d\omega}(f_c) - \frac{d\phi}{d\omega}(f)\right|$$

ahol:

f_c a prekorrelációs sávszűrő középfrekvenciája;

f bármilyen frekvencia az előkorrelációs szűrő 3 dB-es sávszélességén belül;

ϕ az előkorrelációs sávszűrő és az antenna összekapcsolt fázis válasza; és

ω egyenlő 2πf-el.

8.11.4 Az olyan légijármű fedélzeti vevőknél, amelyek korai-késői korrelátorokat használnak és a GPS műholdakat követik, a berendezés előkorrelációs sávszélesség a korrelátor térköz és a differenciál csoportfutási idő a D-11. táblázatban meghatározott tartományon belül van.

8.11.5 Az olyan légijármű fedélzeti vevőknél, amelyek korai-késői korrelátorokat használnak és a GLONASS műholdakat követik, a berendezés előkorrelációs sávszélesség a korrelátor térköz és a differenciál csoport-futási idő a D-12. táblázatban meghatározott tartományon belül van.

8.11.6 Az olyan légijármű fedélzeti vevőknél, amelyek kettős-delta korrelátorokat használnak és a GPS műholdakat követik, a berendezés előkorrelációs sávszélesség a korrelátor térköz és a differenciál csoport-futási idő a D-13. táblázatban meghatározott tartományon belül van.

8.11.7 Az olyan légijármű fedélzeti vevőknél, amelyek korai-késői, vagy kettős-delta korrelátorokat használnak és az SBAS műholdakat követik, a berendezés előkorrelációs sávszélesség a korrelátor térköz és a differenciál csoport-futási idő a D-14. táblázatban meghatározott tartományon belül van.

9. Állapot ellenőrzés és NOTAM

9.1 Rendszer állapot

9.1.1 A Földi Bázisú Kiegészítő Rendszer /GBAS/ teljesítőképesség csökkenésének általában helyi hatásai vannak, és ez főleg a megközelítési üzemeltetésekre hat. A GBAS rendszer teljesítőképesség csökkenését a megközelítési vonatkozású információkhoz kell szolgáltatni.

9.1.2 A műhold helyzetsor rendszer(ek), vagy a Műhold Bázisú Kiegészítő Rendszer /SBAS/ teljesítőképesség csökkenésének nem csak helyi hatása van, hanem kiegészítő következményei lesznek egy szélesebb területre, és közvetlen hatással lehet az útvonal-repülési üzemeltetésekre. Ezeknek az elemeknek a teljesítőképesség csökkenését a területi vonatkozású információkhoz kell szolgáltatni. Egy példa erre egy műhold hibája.

9.1.3 A GRAS működés teljesítőképesség csökkenésének helyi és/vagy nagy területű hatásai lehetnek. Ennek megfelelően, ha a teljesítőképesség csökkenésnek csak helyi hatásai vannak, a GRAS rendszer teljesítőképesség csökkenési információját a 9.1.1 pontnak megfelelően kell szolgáltatni. Ha a teljesítőképesség csökkenésnek nagy területű hatásai vannak, a GRAS rendszer teljesítőképesség csökkenési információját a 9.1.2 pontnak megfelelően kell szolgáltatni.

9.1.4 Az információt úgy kell szolgáltatni, hogy jelezze a GNSS-nek egy meghatározott üzemeltetés alátámasztására vonatkozó képtelenségét. Például a GPS/SBAS lehet, hogy nem támasztja alá egy meghatározott megközelítés precíziós megközelítési üzemeltetését. Ezt az információt automatikusan, vagy kézi bevitellel lehet létrehozni a rendszer teljesítmény modelljére alapozva.

D-11. táblázat: GPS nyomkövetési korlátozások a korai-késői korrelátorokra

Tartomány	3 dB-es előkorrelációs sávszélesség, BW	Átlagos korrelátor térköz (chipek)	Pillanatnyi korrelátor térköz (chipek)	Differenciál csoport-futási késleltetési idő
1	2 < BW ≤ 7 MHz	0,045 – 1,1	0,04 – 1,2	≤ 600 ns
2	7 < BW ≤ 16 MHz	0,045 – 0,21	0,04 – 0,235	≤ 150 ns
3	16 < BW ≤ 20 MHz	0,045 – 0,12	0,04 – 0,15	≤ 150 ns
4	20 < BW ≤ 24 MHz	0,08 – 0,12	0,07 – 0,13	≤ 150 ns

D-12. táblázat: GLONASS nyomkövetési korlátozások a korai-késői korrelátorokra

Tartomány	3 dB-es előkorrelációs sávszélesség, BW	Átlagos korrelátor térköz tartomány (chipek)	Pillanatnyi korrelátor térköz tartomány (chipek)	Differenciál csoport-futási késleltetési idő
1	7 < BW ≤ 9 MHz	0,05 – 1,0	0,045 – 1,1	≤ 100 ns
2	9 < BW ≤ 15 MHz	0,05 – 0,2	0,045 – 0,22	≤ 100 ns
3	15 < BW ≤ 18 MHz	0,05 – 0,1	0,045 – 0,11	≤ 100 ns

D-13. táblázat: GPS nyomkövetési korlátozások a kettős-delta korrelátorokra

Tartomány	3 dB-es előkorrelációs sávszélesség, BW	Átlagos korrelátor térköz tartomány (chipek)	Pillanatnyi korrelátor térköz tartomány (chipek)	Differenciál csoport-futási késleltetési idő
1	2 < BW ≤ 7 MHz	0,045 – 0,6	0,04 – 0,65	≤ 600 ns
2	7 < BW ≤ 14 MHz	0,045 – 0,24	0,04 – 0,26	≤ 150 ns
3	14 < BW ≤ 16 MHz	0,07 – 0,24	0,04 – 0,26	≤ 150 ns

D-14. táblázat: SBAS távolság-meghatározási funkció nyomkövetési korlátozások

Tartomány	3 dB-es előkorrelációs sávszélesség, BW	Átlagos korrelátor térköz (chipek)	Pillanatnyi korrelátor térköz (chipek)	Differenciál csoport-futási késleltetési idő
1	2 < BW ≤ 7 MHz	0,045 – 1,1	0,04 – 1,2	≤ 600 ns
2	7 < BW ≤ 20 MHz	0,045 –1,1	0,04 – 1,2	≤ 150 ns

9.2 Tájékoztatás a teljesítőképesség csökkenés típusáról

A következő tájékoztatásokat kell szolgáltatni:

a) A szolgáltatás nem-elérhető;

b) A szolgáltatás leminősítését, ha alkalmazható; és

c) A teljesítőképesség csökkenés idejét és várható időtartamát.

9.3 Az értesítések ütemezése

Tervezett eseményeknél az értesítést legalább 72 órával az eseményt megelőzően át kell adni a NOTAM hatóságnak. Nem-tervezett események esetén a NOTAM hatóságot 15 percen belül értesíteni kell. Az értesítést a 15 perces, vagy annál hosszabb időtartamú eseményekről kell adni.

10. Interferencia

10.1 Potenciális interferencia

A műholdas navigációs rendszereknek, azaz a GPS-nek és a GLONASS-nak, jellemzőjük a viszonylag gyenge vett jel teljesítmény, ami azt jelenti, hogy egy interferencia jel létrehozhatja a szolgáltatás elvesztését. A szolgáltatás fenntartása céljából szükséges lesz annak biztosítása, hogy a Szabványok és Ajánlott Gyakorlatokban /SARPs/ meghatározott maximális interferencia szintek ne kerüljenek túllépésre.

10.2 Az antenna bemenet interferencia küszöbének meghatározása

Az interferencia küszöb szintek jelzései az antenna bemenetre vannak vonatkoztatva. Ebben az összefüggésben az „antenna bemenet” kifejezés az antenna és a GNSS vevő közötti kapcsolatot jelenti, ahol a műhold jel teljesítménye megfelel a névleges minimális vett jel teljesítménynek, ami -164,5 dBW a GPS-re és -165,5 dBW a GLONASS-ra. A potenciális interferencia forrástól való lecsökkent távolság miatt azoknak a GNSS vevőknek, amelyek a repülés megközelítési szakaszában használatosak, magasabb interferencia küszöbjük van, mint azoknak a vevőknek, amelyek csak az útvonal-repülési navigációra használatosak.

10.3 Sávon-belüli interferencia források

A sávon-belüli káros interferencia potenciális forrása bizonyos Államokban az Állandóhelyű szolgálatok működése. Bizonyos Államokban van olyan elsődleges kiosztás a pont – pont mikróhullámú összeköttetési állandóhelyű szolgálatok számára, amelyek a GPS és a GLONASS által használt frekvenciasávban működnek.

10.4 Sávon-kívüli interferencia források

A sávon-kívüli potenciális interferencia források magukba foglalják a légiforgalmi VHF és UHF adások harmonikus és zavaró sugárzásait. A sávon-kívüli zaj a rádió és TV műsorszórás diszkrét zavaró termékei és keresztmodulációs termékei ugyancsak interferencia problémákat okozhatnak.

10.5 Légijármű által létrehozott források

10.5.1 A légijárműveken lévő GPS és GLONASS berendezések potenciális káros interferenciája a légijármű típusától, annak méretétől és a felszerelt adó berendezéstől függ. A GNSS antenna elhelyezésnél számításba kell venni a fedélzeti interferencia lehetőségét (főleg a SATCOM-ét).

10.5.2 Azoknak a GNSS vevőknek, amelyeket a légijármű fedélzetén a SATCOM berendezéssel együtt használnak, magasabb interferencia küszöbjüknek kell lenni az 1 610 MHz és az 1626,5 MHz közötti frekvencia-tartományban, mint az olyan légijárművek fedélzeti vevőinél, amelyeknek nincs SATCOM berendezésük. Ennek megfelelően az interferencia küszöbre vonatkozó előírások különbséget tesznek a két eset között.

Megjegyzés. – A kisugárzott SATCOM légijármű földi állomások határértékei az Annex 10 III. kötete I. része 4. fejezetének 4.2.3.5 pontjában került megadásra.

10.5.3 A fő csökkentési technika a fedélzeti interferenciára magában foglalja az árnyékolást, a szűrést, a vevő felépítési technikát és különösen a nagyobb légijárműveken az antennák fizikai elkülönítését, az adókat és a kábelezést. A vevő felépítési technika magán foglalja az adaptív szűrők és az interferencia törlő technikákat, hogy csökkentsék a keskeny sávon-belüli interferenciát. Az antenna felépítési technikák magukban foglalják az adaptív nulla irányítású antennákat, az antenna nyereségnek az interferencia forrás irányába történő csökkentésére, anélkül, hogy a műholdaktól jövő jel teljesítmény csökkenne.

10.6 Sértetlenség interferencia jelenlétében

A Műhold Bázisú Kiegészítő Rendszer /SBAS/ és a Föld Bázisú Kiegészítő Rendszer /GBAS/ vevőkkel szembeni azon követelmény, hogy ne jelezzenek ki félrevezető információt interferencia jelenlétében, azt célozza, hogy megelőzzék a félrevezető információk kijelzését az olyan nem-tervezett interferencia helyszíneken, amelyek előfordulhatnak. Nem az a szándék, hogy határozottan megcélozzuk a szándékosan előidézett interferenciát. Valójában lehetetlen az, hogy vizsgálatokkal teljes egészében felülvizsgáljuk ezt a követelményt, a teljesítés egy elfogadható eszközét meg lehet találni a megfelelő, az RTCA és az EUROCAE által kiadott Minimális Üzemeltetési Teljesítmény Szabványokban.

11. A GNSS paraméterek rögzítése

11.1 Abból a célból, hogy egy esemény, vagy egy baleset kivizsgálásának utólagos lefolytatása lehetséges legyen (2.Fejezet 2.4.3 pont), a GNSS információkat mindkét helyen, az üzemeltetéshez felhasznált kiegészítő rendszernél és a megfelelő műhold helyzetsor rendszer(ek)nél rögzíteni kell. Ennek megfelelően a rögzítendő paraméterek függetlenek az üzemeltetés típusától, a felhasznált kiegészítő rendszertől és a műhold rendszer elemektől. Egy adott szolgáltatási területen belül az összes, a felhasználók részére rendelkezésre álló paramétert a szolgáltatási területen belüli jellemző helyeken rögzíteni kell.

11.2 Nem az a cél, hogy egy független garanciát biztosítsanak arról, hogy a GNSS pontosan működik, és nem az, hogy a rendszer ellenőrzés egy másik szintjét biztosítsák a rendellenes teljesítmény, vagy a bemenő adatok szempontjából egy NOTAM feldolgozásra. Nem szükségszerű az, hogy a rögzítő rendszer a GNSS szolgáltatástól független legyen, és meg lehet bízni egy másik Államot, vagy mást is. Abból a célból, hogy egy meghatározott GNSS konfiguráció által biztosított helyzet, sebesség és idő jelzések későbbi rekonstrukciója biztosítva legyen, az az ajánlott, hogy az adatokat általában 1 Hz-es ütemmel pontosan 'jegyezzék fel'.

11.3 A GNSS műhold helyzetsor rendszerre a következő ellenőrzött elemeket kell rögzíteni az összes látható műholdra:

a) Az észlelt műhold vivőfrekvencia-zaj sűrűségét (C/N_0);

b) Az észlelt műhold „durva” pszeudo-távolság kódját és vivőhullám fázis méréseit;

c) A sugárzott műhold navigációs közleményeket; és

d) A vonatkozó rögzítő vevő állapot információit.

11.4 Az SBAS-nél a következő ellenőrzött elemeket kell rögzíteni az összes látható geostacionárius műholdról a fentiekben, a GNSS műhold helyzetsor rendszerre megadott ellenőrzött elemeken kívül:

a) Az észlelt geostacionárius műhold vivőfrekvencia-zaj sűrűségét (C/N_0);

b) Az észlelt műhold „durva” pszeudo-távolság kódját és vivőhullám fázis méréseit;

c) A sugárzott SBAS adat-közleményeket; és

d) A vonatkozó rögzítő vevő állapotának információit.

11.5 A GBAS-nél a következő ellenőrzött elemeket kell rögzíteni a fentiekben felsorolt, a GNSS műhold helyzetsor rendszerre és SBAS-re megadott ellenőrzött elemeken kívül (ahogy megfelelő):

a) A VHF adatsugárzási (VDB) teljesítmény szintet;

b) A VDB állapot információit; és

c) A sugárzott GBAS adat-közleményeket.

12. A GNSS teljesítmény értékelése

A 11. rész pontjaiban leírt adatokat a szolgáltatási területen belüli GNSS teljesítmény rendszeresen ismétlődő megerősítésével is alá lehet még támasztani.

13. GNSS és adatbázis

Megjegyzés. – A légiforgalmi adatokra vonatkozó előírásokat az Annex 11 2.fejezete és az Annex 15 3.fejezete foglalja magában.

13.1 Az adatbázis a legfrissebb, az érvényben lévő AIRAC ciklusra vonatkoztatva, ami általában azt jelenti, hogy a legfrissebb adatbázis kerül a rendszerbe betáplálásra az egyes 28 napos periódusonként. Az érvénytelen navigációs adatbázissal történő üzemeltetést el kell kerülni.

13.2 Bizonyos helyzetekben az egy lejárt adatbázis felhasználásával történő üzemeltetést is le lehet biztonságosan folytatni egy módszer végrehajtásával és/vagy olyan eljárások alkalmazásával, amelyek biztosítják azt, hogy a szükséges adatok pontosak. Ezekhez a módszerekhez és/vagy eljárásokhoz az Államok előzetes jóváhagyása szükséges.

13.2.1 Ezeket az eljárásokat a következő módszerek valamelyikére lehet alapozni:

a) Megkövetelni a légijármű személyzetétől, hogy az üzemeltetés előtt ellenőrizzék a kritikus adatbázis információkat a folyamatban lévő közzétételű információkkal szemben. (Ez a módszer növeli a munkaterhelést és gyakorlatilag nem az összes alkalmazásra választható meg.); vagy

b) Lemondani a folyamatban lévő adatbázis iránti követelménytől és a légijármű személyzete által gyakran ellenőrizni az adatbázis információkat. Ezt a lemondást csak nagyon speciális esetekben lehet alkalmazni ott, ahol a légijármű egy szigorúan korlátozott földrajzi területen kerül üzemeltetésre, és ahol a területet egy egyedüli szabályozó ügynökség ellenőrzi, vagy több ügynökség, amelyek koordinálják ezt a folyamatot; vagy

c) Más jóváhagyott módszert alkalmazni, ami a biztonság egyenértékű szintjét biztosítja.

14. A megmaradó hibák modellezése

14.1 A sértetlenségi követelményeknek az SBAS-re és a GBAS-re való alkalmazása megkívánja azt, hogy egy minta-eloszlás kerüljön felhasználásra a pszeudo-távolság hiba jellemzők leírására. A Vízszintes Védelmi Szint/Oldalirányú Védelmi Szint /HPL/LPL/ és a Függőleges Védelmi Szint /VPL/ modellek (lásd 7.5.3 pontot), amelyek megalkotásra kerültek, az egyedi hiba összetevők olyan modelljein alapulnak (a pszeudo-távolság tárgykörében), amelyek függetlenek, nulla-átlagúak, normál eloszlásúak. Ezen modell és a valós hiba eloszlás közötti összefüggést meg kell határozni.

14.2 A védelmi szint kockázat követelmény biztosításának az egyik módját kielégíti a modell négyzetes középeltérés (σ^2) meghatározása úgy, hogy a halmozott hiba eloszlás elégíti ki a feltételeket:

$$\int_y^{\infty} f(x)dx \le Q\left(\frac{y}{\sigma}\right) \qquad \text{az összes } \frac{y}{\sigma} \ge 0 \text{ -ra és}$$

$$\int_{-\infty}^{-y} f(x)dx \le Q\left(\frac{y}{\sigma}\right) \qquad \text{az összes } \frac{y}{\sigma} \ge 0 \text{ -ra}$$

ahol:

f(x) = a valószínűségi sűrűség a légijármű fedélzeti megmaradó pszeudo-távolság hibájának a függvénye, és

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} e^{-\frac{t^2}{2}} dt.$$

14.3 Ezt a módszert közvetlenül lehet alkalmazni akkor, amikor a hiba összetevők nulla-átlagúak, szimmetrikusak és egymódusú valószínűségi sűrűség-függvényük van. Ez a helyzet a vevőnek a helyesbített pszeudo-távolság hibához való hozzájárulásában, mivel a légijármű elemek nincsenek kitéve a kisfrekvenciás megmaradó többutas szóródási hibáknak.

14.4 Ezt a modelt ki lehet terjeszteni a nem-nulla-átlagú megmaradó hibákra, megemelve a model négyzetes középeltérését, úgy, hogy kiegyenlítse a középérték lehetséges hatását a helyzet tartományban.

14.5 A pszeudo-távolság hiba modellek hitelesítésénél számos tényezőt figyelembe kell venni, beleértve:

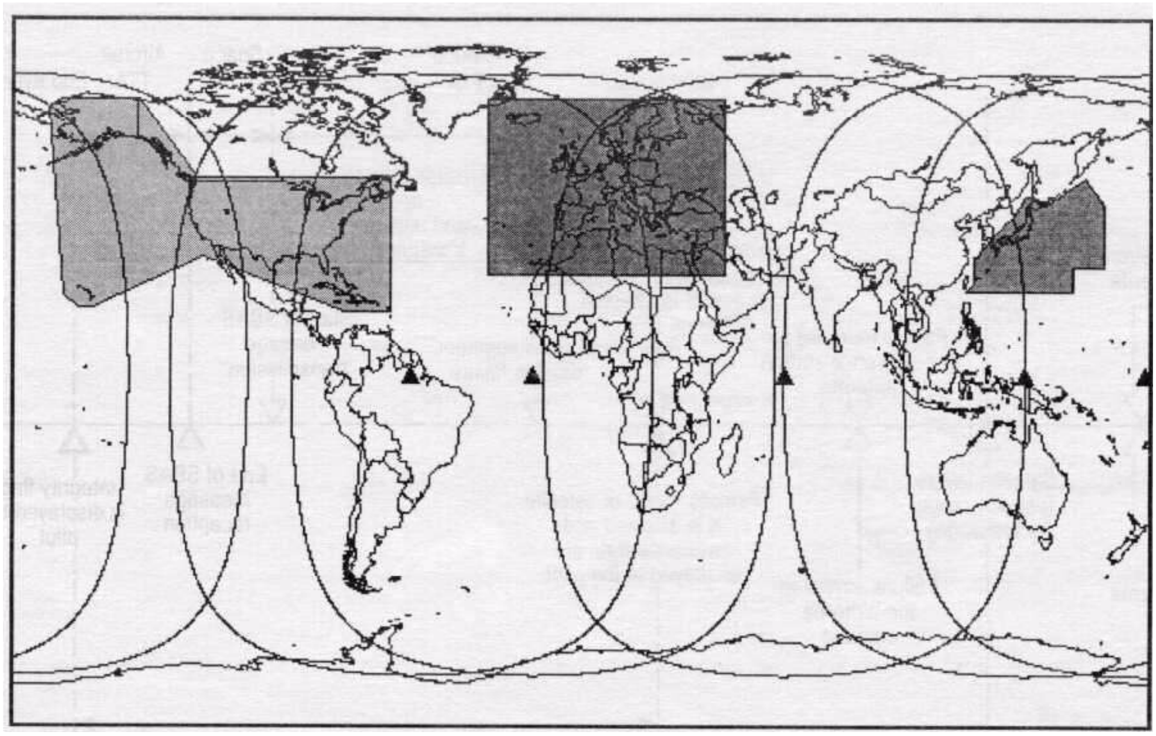
a) A hiba összetevők jellegét;

b) Annak a mintának a méretét, ami az adatgyűjtés és az egyes eloszlások felbecslésének megbízhatóságához szükségesek;

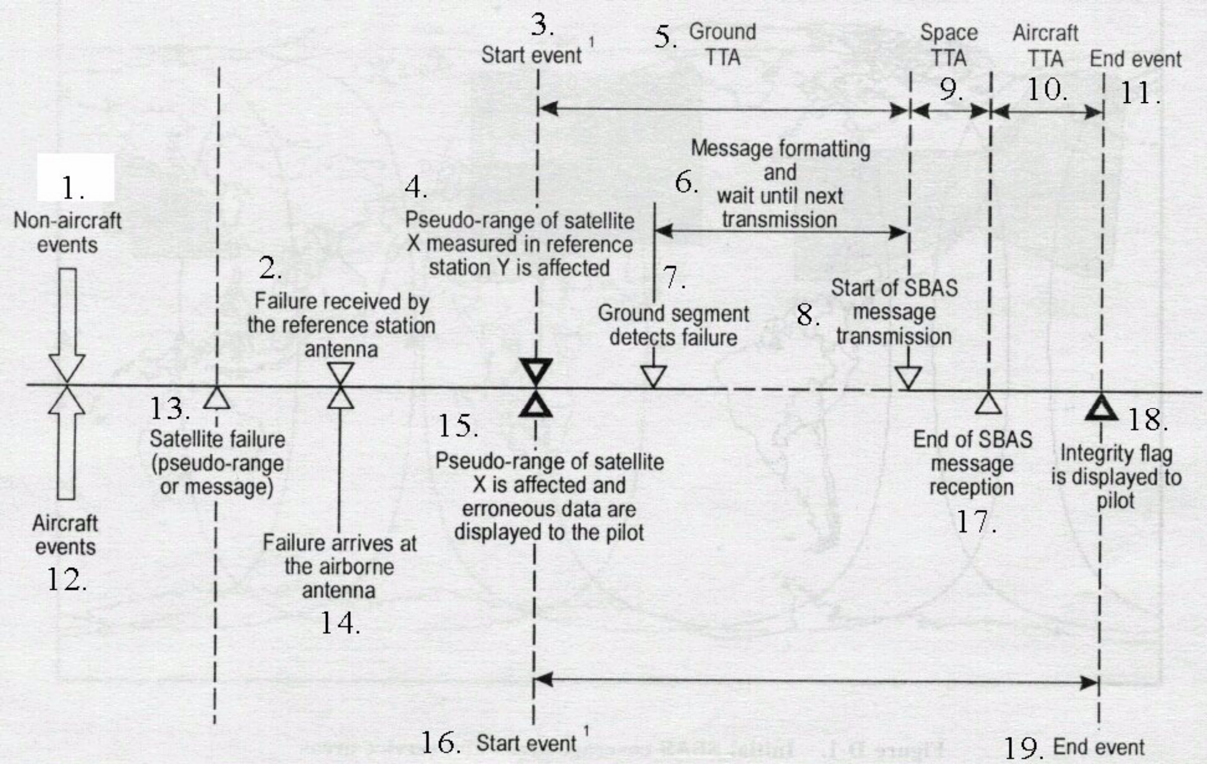
c) A hibák korrelációs idejét; és

d) Az egyes eloszlásoknak a földrajzi helyre és az időre vonatkozó érzékenységét.

Ábrák a "D"- Melléklethez



D-1. ábra: Kiinduló SBAS fedésterületi körzetek és szolgáltatási területek



Megjegyzés: [1]
Mindkét esemény egyidejűnek van tekintve. Pontosan nem ez az eset a meghatározott vevők teljesítmény különbsége miatt. Van egy kis különbség a vevők feldolgozása miatt azon időpontok között, amikor a pszeudo-távolság mérés érintett lesz, és amikor a hibás adat kijelzésre kerül. Gyakorlati okokból ez ebben az ábrában nem jelenik meg.

D-2. ábra: SBAS idő-a-riasztásig /TTA/

Ábraszöveg a D-2. ábrához:

1 – Nem légijármű fedélzeti események
2 – A referencia állomás antennája által vett hiba
3 – Az esemény kezdete[1]
4 – Az X műhold pszeudo-távolsága érintett az Y referencia állomásban mérten
5 – Földi idő-a-riasztásig /TTA/
6 – Közlemény összeállítás és várakozás a következő adásig
7 – A földi rész észleli a hibát
8 – Az SBAS közlemény továbbításának kezdete
9 – Térbeli idő-a-riasztásig
9 – Légijármű fedélzeti idő-a-riasztásig
10 – Az esemény vége
12 – Légijármű földi események
13 – Műhold hiba (pszeudo-távolság, vagy közlemény)
14 – A hiba megérkezik a légijármű fedélzeti antennához
15 – Az X műhold pszeudo-távolsága érintett és hibás adat kerül a légijármű vezető részére kijelzésre
16 – Az esemény kezdete[1]
17 – Az SBAS közlemény vételének vége
18 – A sértetlenségi jelzés a légijármű vezető részére kijelezve
19 – Az esemény vége

"E" MELLÉKLET: A VOR LÉGIJÁRMŰ FEDÉLZETI BERENDEZÉSEK REPÜLÉS ELŐTTI ELLENŐRZÉSÉRE VONATKOZÓ ÚTMUTATÓ ANYAG

1. A VOR légijármű fedélzeti berendezések ellenőrző berendezéseire (VOT) vonatkozó előírások

1.1 Bevezetés

Azon Államok részére, útmutatásként, akik biztosítani kívánnak a VOR légijármű fedélzeti berendezések részére egy repülés előtti ellenőrző mérő jelet, a VOR légijármű fedélzeti berendezések ellenőrző berendezésének (VOT) javasolt jellemzői a következőkben kerülnek megadásra.

1.2 Általános rész

1.2.1 A VOR ellenőrző berendezést (VOT) úgy kell megtervezni, hogy biztosítsa azokat a jeleket, amelyek lehetővé teszik egy tipikus légijármű fedélzeti VOR berendezés kielégítő működését, a repülőtér azon részein, ahol a repülés előtti ellenőrzés elvégzése alkalmas és kívánatos.

1.2.2 A VOR ellenőrző berendezést (VOT) úgy kell megszerkeszteni és beállítani, hogy a légijármű fedélzeti VOR irányszög kijelző akkor jelezze a "FROM" (-tól) nulla fokot, amikor a vevő berendezés nem tér el a kalibrálásától. Ez a kijelzés a légijárműnek a VOR ellenőrző berendezéshez (VOT) viszonyított szögbeli helyzetétől függetlenül a fedésterületen belül állandó marad.

1.2.3 Azon mód következtében, amelynek megfelelően a VOR ellenőrző berendezést (VOT) felhasználják, semmilyen alapvető szükség nincs arra, hogy bármilyen helyen a berendezést megkettőzzék.

1.2.4 A VOR ellenőrző berendezésnek (VOT) olyan rádiófrekvenciás vivőhullámot kell kisugároznia, amely két önálló 30 Hz-es modulációval kerül összekapcsolásra. Ezeknek a modulációknak azonosnak kell lenni a VOR-hoz kapcsolódó referencia fázisú és változó fázisú jelekével. Ezeknek a modulációknak a fázisa független kell, hogy legyen az irányszögtől, és egymással mindig egybe kell esniük.

1.3 Rádiófrekvencia

A VOR ellenőrző berendezésnek (VOT) a 108 MHz-től a 117,975 MHz-ig terjedő frekvenciasávban kell működni egy olyan módon kiválasztott megfelelő VOR csatornán, hogy ne zavarjon semmilyen ultrarövidhullámú navigációs, vagy hírközlési szolgálatot. A legmagasabb kiosztható frekvencia a 117,95 MHz lehet. A rádiófrekvenciás vivőhullám frekvencia tűréshatárának plusz, vagy mínusz 0,005 százaléknak kell lenni, kivéve azt, ami a 3. Fejezet 3.3.2.2 és 3.3.2.3 pontjában meghatározásra került.

1.4 Polarizáció és pontosság

1.4.1 A VOR ellenőrző berendezés (VOT) sugárzásának vízszintesen polarizáltnak kell lenni.

1.4.2 A VOR ellenőrző berendezéstől (VOT) eredő sugárzás által továbbított "iránymérési" pontosságnak plusz, vagy mínusz 1 foknak kell lenni.

Megjegyzés. - Mivel a rádióferekvenciás vivőhullámon a két moduláció minden időben fázisban van, ezért a maradék függőlegesen polarizált energiának nincs hatása a berendezés pontosságára.

1.5 Fedésterület

1.5.1 A fedésterületi követelmények és ebből eredően az a teljesítmény, amit ki kell sugározni, szükségszerűen és jelentékeny mértékben a helyi körülményektől függ. Bizonyos telepítési helyeknél olyan kis töredék teljesítmény is, mint az 1 W, kielégítő lesz, míg más esetekben, különösen, ha egy egyedüli berendezés két, vagy több egymáshoz közel álló repülőteret szolgál ki, több-wattos rádiófrekvenciájú teljesítmény kisugárzására lehet szükség.

1.5.2 Ahol szükséges az, hogy azonos csatornájú VOR, VOT és ILS iránysáv adó részére védelmet biztosítsanak a VOT-tól eredő zavarás ellen, ott a rádiósugárzást úgy kell korlátozni, hogy a szükség szerint biztosítva legyen az, hogy a további azonos csatornára kijelölt berendezések zavarása ne forduljon elő.

1.6 Moduláció

1.6.1 A rádiófrekvenciás vivőhulámnak, ahogy az a tér bármely pontjában észlelésre kerül, két jellel amplitúdó-moduláltnak kell lenni a következők szerint:

a) egy állandó amplitúdójú 9 960 Hz-es segédvivő frekvenciának, 30 Hz-es frekvencia-modulációval és 16 plusz, vagy mínusz 1-es (azaz 15-től 17-ig) eltérési viszonnyal;

b) 30 Hz.

1.6.2 A 9 960 Hz-es és a 30 Hz-es jelek modulációs mélységének az egyes összetevőkre a 28 százalékig terjedő határértéken belül kell lenni.

1.6.3 Azt a jelet, amely frekvenciában modulálja a 9 960 Hz-es segédvivő frekvenciát és azt a jelet, amely amplitúdó-modulálja a rádiófrekvenciás vivőhullámot 30 Hz plusz, vagy mínusz 1 százalékon belül kell tartani.

1.6.4 A 9 960 Hz-es segédvivő frekvenciát plusz, vagy mínusz 1 százalékon belül kell tartani.

1.6.5 Az adó kimeneten lévő 9 960 Hz-es segédvivő frekvencia amplitúdó-modulációjának százalékos értéke nem lehet 5 százaléknál nagyobb.

1.7 Azonosítás

1.7.1 A VOR ellenőrző berendezésnek (VOT) egy 1 020 Hz-es azonosító jelet kell adni. A VOR ellenőrző berendezés (VOT) azonosító kódját az illetékes hatóságnak úgy kell kiválasztani, hogy az összetéveszthetetlenül megkülönböztető legyen az ellenőrző feladatot adóan, és ha szükséges, a telepítési helyet illetően is.

Megjegyzés. - Egy Államban ott, ahol a VOR ellenőrző berendezés (VOT) fedésterülete egy egyedüli repülőtérre korlátozódik, az azonosítás egy folyamatos pont-sorozatot tartalmaz.

1.7.2 A rádiófrekvenciás vivőhullámnak az azonosító jellel történő modulációja mélységének körülbelül 10 százaléknak kell lenni.

1.8 Felügyelő rendszer

1.8.1 Alapjában véve nincs szükség a VOR ellenőrző berendezés (VOT) folyamatos automatikus felügyelő figyelésére, feltéve, hogy az amplitúdó-modulált és a frekvencia-modulált 30 Hz-es összetevőinek relatív fázisa mechanikusan szinkronizálva van, és berendezések állnak rendelkezésre a VOR ellenőrző berendezés (VOT) állapotának rendszeres ellenőrzésére és távolból történő felügyeletére.

1.8.2 Az automatikus felügyelő rendszer biztosítása megkettőzheti a VOR ellenőrző berendezés (VOT) telepítési költségét, és ennek megfelelően több illetékes hatóság valószínűleg csak a távoli felügyelő és vezérlő pont létrehozását alkalmazza. Azonban ahol az Állam a VOR ellenőrző berendezés üzemeltetési felhasználása figyelembevételével úgy dönt, hogy automatikus felügyeletet biztosít, ott a felügyelő rendszernek egy figyelmeztető jelzést kell továbbítani egy vezérlő pontra, és le kell állítania az adást, ha a megállapított feltételekhez képest a következő eltérések valamelyike fennáll:

a) a VOR ellenőrző berendezés (VOT) által kisugárzott "iránymérési" információnak - az ellenőrző berendezés helyén mért - 1 fokot meghaladó változása;

b) a felügyelő rendszer helyén, a 9 960 Hz-es, vagy a 30 Hz-es jelek szintjének az 50 százalékos csökkenése.

A felügyelő rendszer meghibásodásának automatikusan be kell szüntetnie az adást.

2. A repülőtéri VOR ellenőrző-pontok kiválasztása és felhasználása

2.1 Általános rész

2.1.1 Amikor egy, a repülőtérhez viszonyítottan megfelelően elhelyezkedő VOR berendezés rendelkezésre áll a légijármű fedélzeti VOR berendezések repülés előtti ellenőrzéséhez, akkor az ellenőrzést a repülőtér alkalmas részein elhelyezett, megfelelően kalibrált és jelzett ellenőrző-pontokkal lehet megkönnyíteni.

2.1.2 Az előforduló körülmények széleskörű eltérései következtében gyakorlatilag nem valósítható meg az, hogy bármilyen szabvány követelményt, vagy gyakorlatot meghatározzunk a repülőtéri VOR ellenőrző-pontok kiválasztásához. Azonban azon Államok részére, amelyek biztosítani kívánják ezt a lehetőséget, a felhasználható pontok kiválasztásához útmutatásként szolgálhatnak a következő megfontolandó tényezők.

2.2 Az ellenőrző-pontok elhelyezési követelményei

2.2.1 A közeli VOR jel erősségének kielégítőnek kell lenni ahhoz, hogy biztosítsa egy jellemző légijármű fedélzeti VOR berendezés kielégítő működését. Kihangsúlyozottan a teljes zászló működést (nem látható zászló) kell biztosítani.

2.2.2 Az ellenőrző-pontokat az üzemeltetési megfelelés határértékein belül, épületektől, vagy egyéb olyan tükrözést okozó tárgyaktól (állandó jellegű, vagy mozgó) távol kell elhelyezni, amelyek esetleg csökkenthetik a VOR jelek pontosságát, vagy stabilitását.

2.2.3 A vett VOR iránymérésnek bármely kiválasztott ponton ideálisan plusz, vagy mínusz 1,5 fokon belül kell lenni, a felméréssel, vagy térkép-szerkesztéssel pontosan meghatározott irán: iránnyméréshez viszonyítva.

Megjegyzés. - A plusz, vagy mínusz 1,5 fok értéknek nincs olyan közvetlen üzemeltetési jelentősége, hogy a vett iránymérés a közzétett iránymérés legyen, azonban, ahol egy nagyobb eltérést észlelnek, ott fennáll a rossz stabilitás bizonyos lehetősége.

2.2.4 A kiválasztott pont VOR informcióját üzemeltetésileg csak akkor lehet felhasználni, ha a közzétett irányméréshez viszonyítva egyenletesen plusz, vagy mínusz 2 fokon belülinek találják. A VOR informciónak a kiválasztott pontnál való stabilitását egy kalibrált vevő berendezéssel rendszeres időközönként ellenőrizni kell annak biztosításához, hogy a plusz, vagy mínusz 2 fokos tűréshatár a VOR vevő antenna tájolási helyzetétől függetlenül kielégítésre kerüljön.

Megjegyzés. - A plusz, vagy mínusz 2 fokos tűréshatár a kiválasztott ponton az információ állandóságára vonatkozik, és magába foglalja a pont ellenőrzésére használt kalibrált VOR vevő pontosságának kismértékű tűrését is. A 2 fokos érték nem vonatkozik a légijármű fedélzeti VOR berendezés alkalmassági, vagy alkalmatlansági értékére, ez a Hatóságok és a felhasználók döntésének ügye a végrehajtandó üzemeltetések figyelembevételével.

2.2.5 Azokat az ellenőrző-pontokat, amelyek ki tudják elégíteni a fentiekben megadott követelményeket, az érintett üzemeltetőkkel történő egyeztetés után kell kiválasztani. Az ellenőrző-pontok biztosítása általában a várakozó kitérőkben, a futópályák végein, valamint a karbantartási és rakodási területeken kívánatos.

2.3 A VOR ellenőrző-pontok jelölése

Minden egyes VOR ellenőrző-pontot megkülönböztető módon kell megjelölni. Ennek a jelölésnek magába kell foglalnia azt a VOR iránymérést, amit a légijármű vezetője a légijármű fedélzeti VOR berendezésen venni fog akkor, ha a berendezése pontosan működik.

2.4 A VOR ellenőrző-pontok felhasználása

Az a pontosság, amellyel a légijármű vezetőjének meg kell határoznia a légijárműnek az ellenőrző-ponthoz viszonyított helyzetét, a VOR állomás távolságától függ. Azokban az esetekben, ahol a VOR viszonylag közel van az ellenőrző-ponthoz, különös figyelmet kell fordítani arra, hogy a légijármű VOR vevő antennája közvetlenül az ellenőrző-pont felett legyen.

"F" MELLÉKLET: A RÁDIÓÖSSZEKÖTTETÉSI ÉS NAVIGÁCIÓS BERENDEZÉSEK MEGBÍZHATÓSÁGÁRA ÉS ÜZEMKÉSZSÉGÉRE VONATKOZÓ ÚTMUTATÓ ANYAG

1. Bevezetés és alapvető fogalmak

Ennek a Mellékletnek az a célja, hogy útmutató anyagként szolgáljon azon Tagállamok részére, amelyek hasznosnak találják az üzemeltetési követelményekkel megegyező berendezés megbízhatósági és üzemkészségi fok megadását.

Az ebben a Mellékletben lévő anyag célja az, hogy útmutató és tisztázó célra szolgáljon, és nem képezi az ebben az Annex-ben lévő Szabványok és Ajánlott Gyakorlatok részét.

1.1 Meghatározások

Facility availability. Berendezés üzemkészsége
A tényleges üzemelési időnek a meghatározott üzemelési időhöz viszonyított aránya.

Facility failure. Berendezés meghibásodása
Bármilyen olyan előre nem várt esemény, amely egy olyan üzemeltetésileg jelentős időtartamot hoz létre, amelynek során egy berendezés a meghatározott tűréshatárok között nem biztosítja szolgáltatását.

Facility reliability. Berendezés megbízhatósága
Az a valószínűség, hogy a földi berendezés a meghatározott tűréshatárok között üzemel.

Megjegyzés. - Ez a meghatározás arra a valószínűségre utal, hogy a berendezés egy meghatározott időtartamon keresztül üzemelni fog.

Mean time between failure (MTBF). A meghibásodások közötti átlag idő (MTBF)
Egy berendezés tényleges működési ideje osztva az ugyanazon időtartam alatti összes berendezés meghibásodás számával.

Megjegyzés. - Az üzemelési idő általában úgy kerül megálasztásra, hogy magába foglaljon legalább öt - de inkább több - berendezés meghibásodást abból a célból, hogy a kapott szám egy elfogadhatóbb mértékű bizonyosságot adjon.

Signal reliability. Jel megbízhatóság
Az a valószínűség, hogy az előírt jellemzőjű térbeli jel a légijármű részére rendelkezésre áll.

Megjegyzés. - Ez a meghatározás arra a valószínűségre utal, hogy a jel egy meghatározott időtartamon keresztül rendelkezésre áll.

1.2 Berendezés megbízhatóság

1.2.1 A megbízhatóság tényezők kombinációja által érhető el.
Ezek a tényezők változók és egyedileg lehet azokat szabályozni egy olyan egységes megközelítéssel, ami optimális, és összhangban áll az egyedi környezet körülményeivel és szükségleteivel. Egy tényező bizonyos mértékben ellensúlyozható lehet, például az alacsony megbízhatóság, a megnövelt karbantartó személyzet biztosításával és / vagy a berendezés tartalékolásával. Hasonlóképpen a karbantartó személyzet alacsony szintű hozzáértése a nagy megbízhatóságú berendezés biztosításával.

1.2.2 A következő képlet százalékban fejezi ki a berendezés megbízhatóságot:

$$R=100\ e^{-t/m}$$

ahol:

R = megbízhatóság (annak a valószínűsége, hogy a berendezés az előírt tűréshatáron belül üzemképes lesz a t idő alatt, azonkívül ezt úgy is nevezik, hogy a hibamentes működés valószínűsége, P_S);

e = a természetes logaritmus alapja;

t = az érintett időtartam;

m = a meghibásodások közötti átlag idő.

Látható az, hogy a megbízhatóság úgy növekszik, ahogy a meghibásodások közötti átlag idő (MTBF) növekszik. Egy magasfokú megbízhatósághoz és a t üzemeltetési szempontból jelentős értékeihez nagy meghibásodások közötti átlag időre lesz szükség, ennek megfelelően a meghibásodások közötti átlag idő a megbízhatóság kifejezésének egy másik, jóval megfelelőbb módja.

1.2.3 A gyakorlati tapasztalatok azt mutatják, hogy a fenti képlet az elektronikus berendezések többségére igaz ott, ahol a meghibásodások a Poisson féle eloszlást követik. Nem lesz alkalmazható a berendezés működésének kezdeti idején, amikor viszonylag nagyszámú az egyedi alkatrészek idő előtti meghibásodása, és akkor sem lesz igaz, amikor a berendezés közeledik a felhasználhatósági idejének végéhez.

1.2.4 Számos berendezés típusnál, amely hagyományos alkatrészeket használ fel, 1 000 órás, vagy annál több meghibásodások közötti átlag időt értek el. Az 1 000 órás meghibásodások közötti átlag idő jelentőségének jelzésére a megfelelő 24 órás megbízhatóság körülbelül 97,5 százalékos (azaz a berendezés meghibásodási valószínűség egy 24 órás időtartam alatt körülbelül 2,5 százalék).

1.2.5 Az F-1. számú ábra mutatja be a berendezés hibamentes működésének, P_S, az egy t időtartam utáni valószínűségét különféle meghibásodások közötti átlag idő értékekre.

Megjegyzés. - Fontos az, hogy annak valószínűsége, hogy a hibamentes működés időtartama egyenlő legyen a meghibásodások közötti átlag idővel (MTBF), csak 0,37 (37 százalék); ennek megfelelően nem feltételezett az, hogy a meghibásodások közötti átlag idő meghibásodás- mentes időtartam.

1.2.6 Látni lehet azt, hogy a meghibásodások közötti átlag idő szabályozása létre fogja hozni a megbízhatóság kívánt fokát. Azok a tényezők, amelyek hatással vannak a meghibásodások közötti átlag időre, és ebből eredően a berendezés megbízhatóságára, a következők:

a) a berendezés velejáró megbízhatósága;

b) a tartalékolás foka és típusa;

c) a kiszolgáló ellátó berendezések megbízhatósága, például az energiaellátásé, a telefoné, vagy a vezérlő vonalaké;

d) a karbantartás foka és minősége;

e) környezeti tényezők, például a hőmérséklet és a páratartalom.

1.3 A berendezés üzemkészsége

1.3.1 Az üzemkészséget, százalékban, ki lehet fejezni a tényleges üzemelési időt az egy hosszú időszakot vevő meghatározott üzemeltetési idő elosztásával kapott arányban.

Jelképesen,

$$A = \frac{\text{tényleges üzemelési idő (100)}}{\text{meghatározott üzemelési idő}}$$

Például, ha egy berendezés összességében 700 órát működött szabályszerűen egy 720 órás hónapban, akkor abban a hónapban az üzemkészsége 97,2 százalék volt.

1.3.2 A magasfokú berendezés üzemkészség biztosításához fontos tényezők a következők:

a) berendezés megbízhatóság;

b) a karbantartó személyzetnek a meghibásodásokra történő gyors intézkedése;

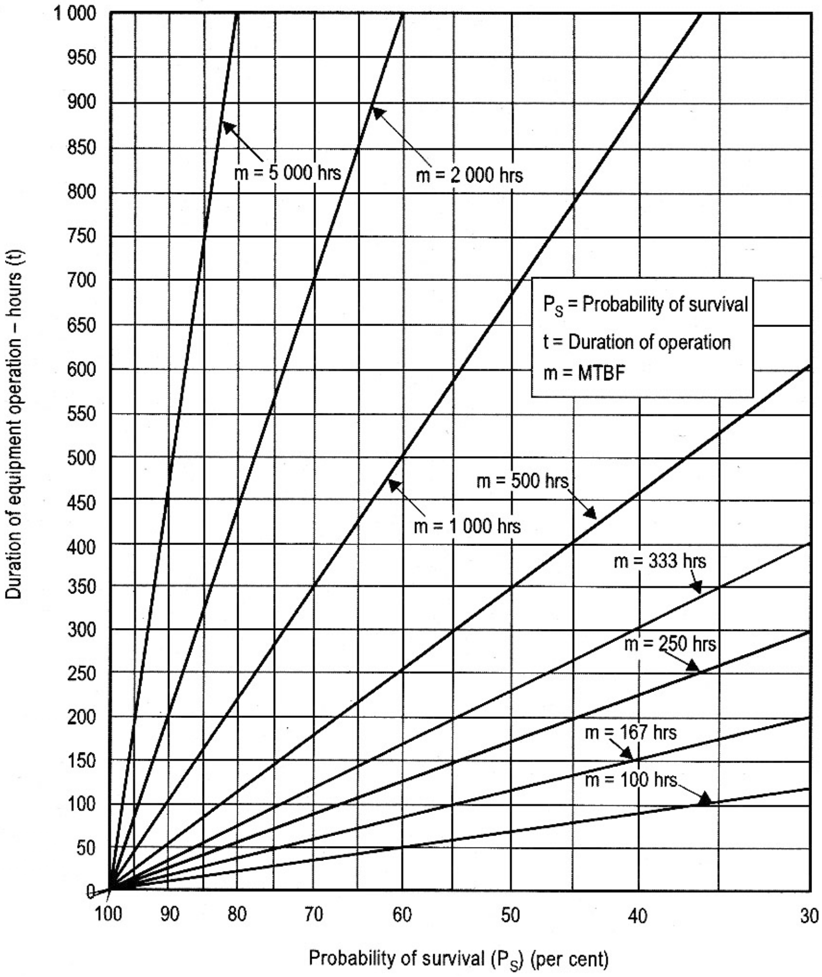
c) a karbantartó személyzet kielégítő gyakorlata;

d) olyan berendezés tervezés, amely biztosítja az alkarészekhez való jó hozzáférhetőséget és karbantarthatóságot;

e) hatékony logisztikai alátámasztás;

f) a megfelelő ellenőrző berendezések biztosítása;

g) készenléti berendezések és / vagy eszközök.



Vízszintes tengely = P_S – fennmaradási valószínűség százalékban
Függőleges tengely = berendezés üzemelési ideje órában
m = A meghibásodások közötti átlag idő (MTBF)

F-1. ábra: A Ps = 100 e-t/m szerkesztése

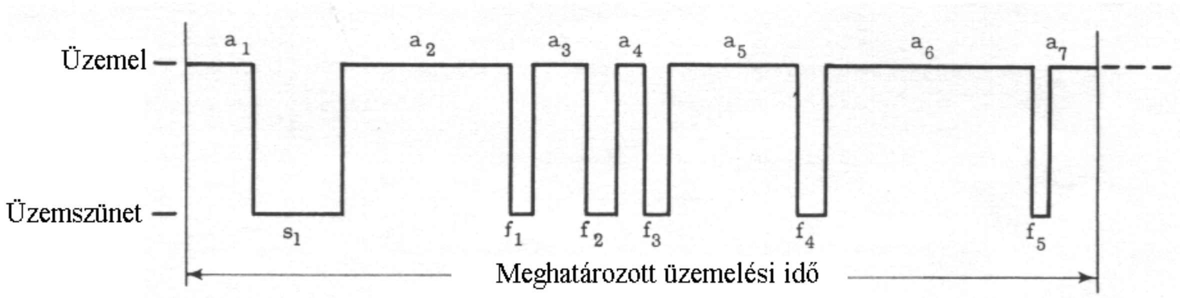
2. A megbízhatóság és üzemkészség gyakorlati szempontjai

2.1 A megbízhatóság és az üzemkészség mérése

2.1.1 *Megbízhatóság.* Azt az értéket, amit a meghibásodások közötti átlagos idő ad, a gyakorlatban szükségszerűen egy becslésnek kell tekinteni, mivel a méréseket egy véges időtartamon keresztül kell végezni. A meghibásodások közötti átlag időnek egy véges időtartamon keresztüli mérése lehetővé teszi a Hatóságok részére a berendezéseik megbízhatósági variációinak a meghatározását.

2.1.2 *Üzemkészség (rendelkezésre állás).* Ez ugyancsak fontos abbban, hogy egy jelzést biztosít arról a fokról, amelynek megfelelően egy berendezés (vagy a berendezések csoportja) a felhasználók rendelkezésére áll. Az üzemkészség közvetlenül vonatkozik arra az elért hatékonyságra, hogy hogyan álítják vissza a berendezéseket a szabályos szolgáltatásukba.

2.1.3 Az alap mennyiségeket és a méréseik módszerét az F-2. számú ábra mutatja be. Ezeknek az értékeknek nem az a céljuk, hogy egy olyan jellemző helyzetet mutassanak be, ami szabályszerűen nagyobb számú üzemképtelen időtartamot foglal magába a meghatározott üzemelési idő alatt. Azt is el kell fogadni, hogy a megbízhatóság és üzemkészség legcélszerűbb értékeinek megkapásához annak a meghatározott üzemelési időnek, amely során a méréseket végzik, olyan hosszúnak kell lenni, ami gyakorlatilag csak lehetséges.



Tényleges üzemelési idő = $a_1 + a_2 + a_3 + a_4 + \ldots a_n$
a = üzemelési időtartam
Üzemszüneti idő = $s_1 + \ldots + s_n + f_1 + f_2 + \ldots + f_n$
s = tervezett leállítási időtartam
f = hiba időtartam
Meghatározott üzemelési idő = A tényleges üzemelési idő és az üzemszüneti idő összege

F-2. ábra: A berendezés üzemkészségének és megbízhatóságának értékelése

2.1.4 Az F-2. ábrán bemutatott mennyiségeket alkalmazva, amelyek egy tervezett leállítási időtartamot és öt hiba időtartamot foglalnak magukba, ki lehet számítani a meghibásodások közötti átlag időt (MTBF) és az üzekészség (A) idejét a következők szerint:

Legyen:

$a_1 + a_2 + a_3 + a_4 + a_5 + a_6 + a_7$	=	5 540 óra
s_1	=	20 óra
f_1	=	2 1/2 óra
f_2	=	6 1/4 óra
f_3	=	3 3/4 óra
f_4	=	5 óra
f_5	=	2 1/2 óra
Meghatározott üzemelési idő	=	5 580 óra

Meghibásodások közötti átlag idő:

$$\text{MTBF} = \frac{\text{Tényleges üzemelési idő}}{\text{A hibák száma}} = \frac{\sum_{i=1}^{7} a_1}{5}$$

$$= \frac{5540}{5} = 1\,108 \text{ óra}$$

Üzemkészség:

$$A = \frac{\text{Tényleges üzemelési idő x 100}}{\text{Meghatározott üzemelési idő}} = \frac{\sum_{i=1}^{7} a_i \times 100}{\sum_{i=1}^{7} a_i + s_1 + \sum_{i=1}^{5} f_i}$$

$$= \frac{5540}{5580} \text{x}100 = \text{99,3 százalék}$$

"G" MELLÉKLET: TÁJÉKOZTATÁSOK ÉS ÚTMUTATÓ ANYAG AZ MLS SZABVÁNYOK ÉS AJÁNLOTT GYAKORLATOK ALKALMAZÁSÁHOZ

1. Meghatározások

(lásd még a 3. Fejezet 3.11.1 pontját)

Dynamic side-lobe level. Dinamikus oldalszirom szint
Az a szint, amely az idő 3 százalékában meghaladja a letapogató antenna távoli térerősségi sugárzási karakterisztikájának a fősugárnyalábján kívüli részét, ahogy azt a funkció letapogatási sebességre egy 26 kHz-es sugárnyaláb burkológörbéjű videoszűrőt alkalmazva mérik. A 3 százalékos szintet az oldalszirom időtartam arány azon része határozza meg, amely meghaladja a teljes letapogatási időtartamra meghatározott szintet.

Effective side-lobe level. Tényleges oldalszirom szint
A letapogató sugárnyaláb oldalszirmának az a szintje, amelyen belül egy meghatározott többutas környezet sajátos útirány-vezetési szög hibát eredményez.

MLS point D. MLS D-pont
A futópálya középvonala felett 2,5 m (8 láb) magasságú és a futópálya küszöbétől az oldalszög antenna irányában 900 méter (3 000 láb) távolságra lévő pont.

MLS point E. MLS E-pont
A futópálya középvonala felett 2,5 m (8 láb) magasságú és a futópálya megállási küszöbétől a futópálya küszöbe irányában 600 méter (2 000 láb) távolságra lévő pont.

Standard receiver. Szabvány vevőkészülék
Az a légijármű fedélzeti vevő modell, amelyről feltételezett az, hogy szétválasztja az MLS hiba összetevőket. A kiemelkedő jellemzők a következők: (1) a jelfeldolgozás a sugárnyaláb középpontok mérésén alapszik; (2) elhanyagolható a központosítási hiba; (3) a kormányzási elmozdulási zaj (CMN) a 3. Fejezet 3.11.6.1.1.2 pontban megadott értékeknél kisebb, vagy azzal egyenlő; (4) egy 26 kHz-es sávszélességű kétpólusú aluláteresztő sugárnyaláb burkológörbe szűrővel felszerelt; és (5) a szögadat kimeneti szűrést egy egypólusú aluláteresztő 10 radians/másodperces sarokfrekvenciájú szűrő végzi.

2. A "térbeli jel" jellemzői - szög- és adat funkciók

2.1 A jelformátum szervezése

2.1.1 A jelformátum időosztásos multiplexen alapszik, amelyben az egyes szög útirány-vezetési funkciók egymás után kerülnek kisugárzásra, és valamennyi ugyanazon a frekvencián van kisugározva. A rendszer a szög információkat az egymást követő nagymértékben irányított modulálatlan legyező alakú sugárnyalábok közötti különbség mérésével nyeri. A funkciókat bármilyen sorrendben lehet továbbítani. Ajánlott idõrések biztosítottak a megközelítési oldalszög, a megközelítési magassági szög, a kilebegtetési magasság és a hátsó irányszektor szög funkciók részére. Az egyes letapogatási sugárnyalábokat és az adatok továbbítását megelőzően egy bevezető jelszakasz van, amelyet egy szektor antenna a teljes fedésterületi légtérbe kisugároz. A bevezető jelszakasz azonosítja a következő letapogatási funkciót, és szinkronizálja a légijármű fedélzeti vevőjének jelfeldolgozó áramköreit és logikáját is.

2.1.2 A szögletapogatási funkción kívül vannak az alap és kiegészítő adat funkciók, mindegyikük saját bevezető jelszakasszal, amelyek ugyancsak kisugárzásra kerülnek a szektor antennákról. A bevezető jelszakasz teszi lehetővé az egyes funkciók felismerését és független feldolgozását. Következésképpen funkciókkal lehet kiegészíteni, vagy funkciókat lehet elhagyni a földi rendszer-felépítésből anélkül, hogy az a vevő működésére hatással lenne. A bevezető jelszakaszban és az adat funkciókban alkalmazott kódok differenciális fáziseltolásos kódolással (DPSK) moduláltak.

2.1.2.1 *A differenciális fáziseltolásos kódolású (DPSK) adat jel jellemzők.* A differenciális fáziseltolásos kódolású (DPSK) adatok a rádiófrekvenciás vivőhullám differenciális fázis modulációjával kerülnek leadásra 0, vagy 180 fokos relatív fázis állapottal. A differenciális fáziseltolásos kódolású adat jeleknek a következők a jellemzőik:

adat sebesség 15,625 kHz
bit hossz 64 mikroszekundum
logikai "0" nincs fázis átmenet
logikai "1" fázis átmenet

2.1.3 A szögfunkciók szervezésére és az időzítésre vonatkozó példák a G-1 és a G-2 (az összes ábra a fejezet végén került elhelyezésre) ábrákon kerülnek bemutatásra. Az adat tételek részleteit és meghatározásait a G-1 számú ábra mutatja be, és a 3. Fejezet 3.11.4.8 pontjában kerültek megadásra.

2.1.4 A G-3A, G-3B és G-3C ábrákon bemutatott szög útirány-vezetés és az adatok továbbításának sorrendje bebizonyítja azt, hogy kielégítő szabadságfok van biztosítva a szinkron interferencia ellen.

2.1.4.1 Ezeknek a sorrendeknek a szerkezete arra a célra szolgál, hogy kielégítő véletlenszerű elrendezést biztosítson az olyan szinkron interferencia kizárása érdekében, mint amit a légcsavar forgási hatásai okozhatnak.

2.1.4.2 A G-3A ábrán bemutatott sorrendi párok az összes funkció továbbítását biztosítják. Bármelyik olyan funkciót, amelyre nincsen szükség, törölni lehet, feltéve, hogy a fennmaradó funkciók a kijelölt időperiódusban kerülnek továbbításra.

2.1.4.3 A G-3B ábrán bemutatott sorrendi párok biztosítják a nagysebességű megközelítési oldalszög funkciót. Bármelyik olyan funkciót, amelyre nincsen szükség, törölni lehet, feltéve, hogy a fennmaradó funkciók a kijelölt időperiódusban kerülnek továbbításra

2.1.4.4 A G-3C ábra azt a teljes idő multiplex átviteli ciklust mutatja be, amelyet a G-3A ábrán, vagy a G-2B ábrán bemutatott sorrendi párokból össze lehet állítani. A sorrendek közötti nyitott időperiódusokat lehet a kiegészítő adat szavak - ahogy jelezve van - továbbítására felhasználni. Az alap adat szavakat is le lehet adni bármelyik nyitott időperiódusban.

2.1.4.5 Az A1 - A4, B1 - B39, B40 - B45 és a B55 szavakban meghatározott alap adatok és kiegészítő adatok továbbítására a bemutatott ciklusban kielégítő idő áll rendelkezésre, feltéve, hogy az adatok is nem használt időrések során, vagy a sorrendeken belüli adat szavak részére szánt időrésekben kerülnek leadásra.

2.1.4.6 Jóval hatékonyabb sorrendeket lehet kijelölni a sorrendeken belüli időzítés és a sorrendek közötti közök szabályozásával azért, hogy lehetővé váljon további kiegészítő adat szavak továbbítása. Az ilyen sorrendeket úgy kell meghatározni, hogy a G-3A, G-3B és G-3C ábrákon bemutatott sorrendekkel azonos értékű szabadságfokot biztosítsanak a szinkron interferencia ellen. A frekvencia-tartomány elemzési technikát lehet felhasználni annak kimutatására, hogy az alternatív sorrendek kielégítően véletlenszerűek.

2.2 Szög útirány-vezetési paraméterek

2.2.1 Azok a szög útirány-vezetési paraméterek, amelyek meghatározzák az MLS szög mérési eljárását, a 3. Fejezet 3.11.4.5 pontjában kerültek meghatározásra. Az a két további paraméter, amely a rendszer működésének láthatóvá tételéhez hasznos, a fél-letapogatási idő (T_m) és a szünet idő. Ezeket a 3. Fejezet előírásaiból lehet levezetni, és referenciaként az alábbi táblázatban kerülnek bemutatásra.

A jel formátum fél-letapogatási és szünet ideje
(lásd a G-2 ábrát)

Funkció	*Fél-letapogatási* idő, T_m (μs)*	*Szünet idő (μs)*
Megközelítési oldalszög	7 972	600
Nagysebességű megközelítési oldalszög	5 972	600
Hátsó irányszektor	5 972	600
Megközelítési magassági szög	2 518	400
Kilebegtetési magasság	2 368	800

* A vevő referencia idejéből mérve
(lásd az A-Függelék A-1. táblázatát).

2.2.2 *A funkció időzítési pontossága.* A Baker-kód referencia időmeghatározási pontatlansága miatt és mivel az adó áramkörei a differenciális fázisbillentyűzéses moduláció fázisait, vagy amplitúdóját a fázis átmenetek során simítják, nem lehetséges a jel időzítésének a térbeli jeltől 2 mikroszekundumnál jobb pontosságú meghatározása. Ezért az szükséges, hogy a 3. Fejezet 3.11.4.3.4 pontjában meghatározott időzítési pontosságot a földi berendezésnél mérjék meg. A földi berendezésben megfelelő mérőpontokat kell biztosítani.

2.3 Oldalszög útirány-vezetési funkciók

2.3.1 *Letapogatási konvenciók.* A G-4. ábra mutatja be a megközelítési oldalszög és a hátsó irányszektor letapogatási konvencióit.

2.3.2 *Fedésterületi követelmények.* A G-5. és G-6. ábrák szemléltetik a 3. Fejezet 3.11.5.2.2 pontjában meghatározott oldalszög fedésterületi követelményeket.

2.3.2.1 Amikor a megközelítési oldalszög, vagy a hátsó irányszektor antenna helye a futópálya középvonalától szükségszerűen eltérő helyzetű, akkor a következő tényezőket kell figyelembe venni:

a) a futópálya teljes területének fedésterületi követelményei;

b) a felhasználható vonatkoztatási alappont pontossági követelményei;

c) átmenet a megközelítési oldalszögből a hátsó irányszektorba; és

d) a mozgó járművek, a légijárművek és a repülőtér szerkezete miatti lehetséges zavaró tényezők.

2.3.2.2 Egy eltérő helyzetű oldalszög antenna szabályszerűen úgy van beállítva, hogy a nulla-fokos oldalszög, vagy párhuzamos a futópálya középvonalával, vagy úgy, hogy a tervezett alkalmazás egy üzemeltetésileg előnyös pontjánál metszi a futópálya meghosszabbított középvonalát. A nulla-fokos oldalszögnek a futópálya középvonalához viszonyított irányítottsága a kiegészítő adatokban kerül továbbításra.

2.3.3 *Nagysebességű megközelítési oldalszög.* Ahol a megközelítési arányos útirány-vezetési szektor plusz, vagy mínusz 40 fokos, vagy kevesebb, ott az oldalszög funkciónál egy nagyobb letapogatási sebességet lehet alkalmazni. A nagysebességű megközelítési oldalszög funkció felhasználható a nagy sugárnyaláb szélességű (pl. a 3 fokos) antennák által okozott kormányzási elmozdulási zaj (CMN) növekedés ellensúlyozására. A kormányzási elmozdulási zaj (CMN) csökkentése két előnyt biztosít: 1) csökkenteni lehet a szög útirány-vezetési térbeli jel teljesítménysűrűség követelményeit, és 2) a dinamikus oldalszirom szint követelményeket enyhíteni lehet.

2.3.3.1 Általában ez a funkció csökkenteni fogja az olyan kormányzási elmozdulási zajt (CMN), mint amilyent a nagy sávszélességű, nem korrelált zajforrások okoznak, szétszórt többutas zajként, vagy vevő termikus zajként egy négyzetgyök 1/3-os tényezővel az alap 13 Hz-es funkció sebességhez viszonyítva. Azonban ezt a teljes négyzetgyök 1/3-os teljesítménysűrűség csökkenést nem lehet realizálni az összes földi antenna sugárnyaláb szélességre azon követelmény miatt, hogy kielégítő teljesítménysűrűséget kell biztosítani az egy egyedüli letapogatáson alapuló jel "megszerzés" érdekében. A differenciális fáziseltolásos kódolású adáshoz szükséges teljesítmény olyan lehet, hogy nem lehet megtakarítást realizálni a földi berendezések adóinál a nagyobb adat sebesség alkalmazásával (lásd a G-1. táblázatot) (Az összes táblázat a fejezet végén került elhelyezésre).

2.3.3.2 Azonban a kormányzási elmozdulási zaj (CMN) teljesítmény vonatkozásában a megnövelt adat sebesség teljes előnye felhasználható. Például a G-2. táblázatban bemutatott minimális jelszinteknél az oldalszög kormányzási elmozdulási zaj (CMN) a 0,10 fokról 0,06 fokra csökkenthető az 1-fokos és 2-fokos sugárnyaláb szélességű antennáknál.

2.3.4 *Kiegészítő biztonsági vezetés*

2.3.4.1 Ahol használatos, ott a kiegészítő biztonsági vezetési impulzusok az arányos útirány-vezetési szektor széleinél a letapogató sugárnyaláb jelek mellett kerülnek kisugárzásra, ahogy azt a G-7. ábra időzítési rajza bemutatja. Az arányos útirány-vezetési szektor határvonala a letapogatási start/stop szögeken belül egy sugárnyaláb szélességnél került megállapításra úgy, hogy a letapogató sugár és a kiegészítő biztonsági jelek közötti átmenet az arányos útirány-vezetési szektoron kívül jelentkezik. Az azokra az összetett hullámformákra vonatkozó példákat, amelyek az átmenet során előfordulhatnak, a G-8. számú ábra mutatja be.

2.3.4.2 Amikor a kiegészítő biztonsági vezetés egy keskeny sugárnyaláb szélességű (például egy fokos) letapogató antennához kapcsolódóan kerül biztosításra, akkor a letapogató sugárnyaláb antenna 15 mikroszekundumig sugároz úgy, hogy közben 'álló helyzetben van' a letapogatási start/stop szögeknél.

2.3.4.3 Bizonyos telepítési helyeknél nehézséget jelenthet a 3. Fejezet 3.11.6.2.5.2 pontjában leírt amplitúdó követelmények kielégítése, a kiegészítő biztonsági vezetési jelek reflexiója miatt. Ezeken a helyeken a letapogatási szektor kibővíthető.

2.3.4.4 Figyelmet kell fordítani a tartson-jobbra / tartson-balra kiegészítő biztonsági vezetés konvenciójának változására akkor, amikor az oldalszög adó berendezések egy ellentétes irányból kerülnek megközelítésre (például: megközelítés a hátsó irányszektor antennája felé).

2.3.5 *A megközelítési oldalszög ellenőrzése.* Az ellenőrzés célja az, hogy a közzétett megközelítési eljárás megfelelő útirány-vezetési teljessége (integritása) szavatolva legyen. Nem az a cél, hogy az összes oldalszög szög egymástól függetlenül ellenőrizve legyen, hanem az, hogy legalább egy megközelítési oldalszög, - szabályszerűen az, amely a futópálya meghosszabbított középvonalával van egy egyenesbe állítva, -ellenőrizve legyen, és az, hogy megfelelő eszközök legyenek, amelyek biztosítják azt, hogy a többi oldalszög szög teljesítménye és teljessége fennmarad.

2.3.6 *Az alsó fedésterületi határ megállapítása.* Amikor a futópálya küszöbe nincs a megközelítési oldalszög antenna rálátási vonalában, akkor a megközelítési oldalszög fedésterületnek a futópálya közelében lévő alsó határvonalát szimulációval és / vagy helyszíni mérésekkel kell meghatározni. Az oldalszög fedésterület közzétett alsó határa a futópálya felülete felett az a magasság, ami kielégíti a 3. Fejezet 3.11.4.9.4 pontjának pontossági követelményeit a helyszíni mérések szerint meghatározva.

2.3.6.1 Ha az üzemeltetések a 2.3.6 pontban elérhető fedésterületi határ alatti fedést tesznek szükségessé, akkor az oldalszög antennát el lehet helyezni a futópálya középvonalától eltérő helyzetben és el lehet tolni a futópálya küszöbe felé úgy, hogy fedje a földetérési területet. A légijármű fedélzeti berendezésnek kell az oldalszög útirány-vezetési, a precíziós távolsági és a földi berendezés telepítési helyének koordinátáit felhasználva kiszámítani a középvonali megközelítést.

2.3.6.2 A számított középvonalas megközelítéssel elérhető leszállási minimum egyebek mellett az MLS megközelítési oldalszög, a DME/P válaszadó és a fedélzeti berendezések kombinált megbízhatóságának és integritásának a függvénye.

2.4 Magassági szög útirány-vezetési funkciók

2.4.1 *Letapogatási konvenció.* A G-9. számú ábra mutatja be a megközelítési magassági szög letapogatási konvenciót.

2.4.2 *Fedésterületi követelmények.* A G-10A. és a G-10B. számú ábra szemlélteti a 3. Fejezet 3.11.5.3.2 pontjában meghatározott magassági szög követelményeket.

2.4.3 *A magassági szög ellenőrzése.* Az ellenőrzés célja az, hogy a közzétett megközelítési eljárás megfelelő útirány-vezetési teljessége (integritása) szavatolva legyen. Nem az a cél, hogy az összes magassági szög egymástól függetlenül megfigyelésre kerüljön, hanem az, hogy legalább egy, - szabályszerűen a minimális siklópálya - kerüljön megfigyelésre, és az, hogy megfelelő eszközök legyenek, amelyek biztosítják azt, hogy a többi magassági szög teljesítménye és teljessége fennmarad.

2.5 Pontosság

2.5.1 *Általános rész*

2.5.1.1 A rendszer pontosság a 3. Fejezetben az útvonal-követési hiba (PFE), útvonal-követési zaj (PFN) és kormányzási elmozdulási zaj (CMN) egységekben került meghatározásra. Ezeknek a paramétereknek az a céljuk, hogy leírják a szög útirány-vezetési jelnek és a légijárműnek a kölcsönhatását, olyan mértékekben, amelyek közvetlenül vonatkoztathatók a légijármű útirány-vezetési hibákra és a repülőgép vezérlő rendszerek tervezésére. Annak megállapítására, hogy a térbeli jel alkalmas-e a légijármű útirány-vezetésére, ezeket a hibákat kell figyelembe venni a vonatkozó frekvencia-tartományban. Az útvonal-követési hiba magába foglalja a közepes irányszög hibát és az útvonal-követési zajt.

2.5.2 *Az MLS mérésének metodikája*

2.5.2.1 Az útvonal-követési hiba (PFE), az útvonal-követési zaj (PFN) és a kormányzási elmozdulási zaj (CMN) a G-11. számú ábrán meghatározott szűrők felhasználásával értékelhető. A szűrő jellemzői a jelenlegi repülőgépek széles körének átviteli tulajdonságain alapulnak, és kielégítőnek tartják belátható időn belüli légijármű tervezés szempontjából is.

2.5.2.2 Míg az útvonal-követési hiba (PFE) szakkifejezés az egy megkívánt repülési pálya és az útirány-vezetési jelet követő repülőgép tényleges repülési pályája közötti különbséget sugalmazza, addig a gyakorlatban ez a hiba úgy kerül kiértékelésre, hogy a légiellenőrzést végrehajtó légijárművezető utasítást kap egy kívánt MLS oldalszögön történő repülésre, és feljegyzik a légijármű fedélzeti berendezésnek az útvonal-követési hiba (PFE) szűrő kimeneti útirány-vezetési kijelzései és az adott légijárműnek egy megfelelő helyzet-referencia alapján meghatározott helyzet mérései közötti különbséget. Ugyanezt a technikát alkalmazzák a megfelelő szűrővel a kormányzási elmozdulási zaj (CMN) meghatározásához.

2.5.2.3 *Hiba kiértékelés.* Az útvonal-követési hiba (PFE) értékeléseket az útvonal-követési hiba (PFE) szűrő kimeneten lehet megkapni (a G-11. sz. ábrán az "A" ellenőrző pont). A kormányzási elmozdulási zaj (CMN) értékeléseket a kormányzási elmozdulási zaj (CMN) szűrő kimeneten lehet megkapni (a G-11.sz. ábrán a "B" ellenőrző pont). A szűrők sarokfrekvenciáit a G-11.számú ábra mutatja be.

2.5.2.3.1 A megközelítési oldalszög, vagy a hátsó irányszektor útvonal-követési hiba (PFE) és kormányzási elmozdulási zaj (CMN) értékeket a fedésterületi határokon belül 40 másodperces időközök során feljegyzett repülési hibaként kell értékelni (azaz T = 40, a G-12. ábrán). A megközelítési magassági szög útvonal-követési hiba (PFE) és kormányzási elmozdulási zaj (CMN) értékeket a fedésterületi határokon belül 10 másodperces időközök során feljegyzett repülési hibaként kell értékelni (azaz T = 10, a G-12. ábrán).

2.5.2.3.2 A 95 százalékos valószínűségi követelmény teljesítését úgy kell értelmezni, hogy az útvonal-követési hiba (PFE), vagy a kormányzási elmozdulási zaj (CMN) értéke a kiértékelési időtartamokban 5 százaléknál nagyobb értékkel nem haladhatja meg a meghatározott hiba határértékeket (lásd a G-12. ábrát).

2.5.2.3.3 Egy másik repülési ellenőrzési eljárást is lehet alkalmazni, olyat, amely nem abszolút vonatkoztatásra támaszkodik. Ebben az eljárásban, az útvonal-követési hiba (PFE) szűrő kimenetén létrejött repülési feljegyzéseknek csak az ingadozási össztevőit mérik, és hasonlítják össze az útvonal-követési zaj (PFN) szabvánnyal. Az útvonal-követési hiba (PFE) átlagos értékére alapfeltételként elfogadják azt, hogy ne haladja meg a légiellenőrzési időtartam során meghatározott közepes irányszög beállítást. Ennek megfelelően a közepes irányszög beállítást hozzáadják az útvonal-követési hiba (PFE) mérésekhez, a meghatározott rendszer útvonal-követési hibával (PFE) történő összehasonlításra. A kormányzási elmozdulási zajt hasonlóképpen lehet kiértékelni, anélkül, hogy a közepes irányszög beállítást számításba vennék.

2.5.2.4 *A földi és a légijármű fedélzeti műszer-hibák.* A földi és a fedélzeti berendezések által létrehozott műszer-hibákat olyan mérésekkel lehet meghatározni, amelyeket visszavert jel nélküli, vagy egyéb, minden olyan terjedési rendellenesség nélküli környezetben végeznek, amely a sugárnyaláb burkológörbéjének zavarását okozhatná.

2.5.2.4.1 Először, a szabvány fedélzeti vevőhöz kapcsolódó műszer-hibákat kell meghatározni egy próbapadi műszer felhasználásával, és a központosítási hibát nullára kell állítani. A fedélzeti berendezés hibáit egy szabvány próbapadi ellenőrző-készlet felhasználásával 40 másodperces adatrögzítéssel lehet venni. Ezután az adatokat négy 10 másodperces időtartományra lehet felosztani. Az egyes időtartományok átlagát kell útvonal-követési hibának (PFE) tekinteni, míg a társult ingadozás négyzetgyökének kétszerese a kormányzási elmozdulási zaj (CMN).

Megjegyzés. - A vevő kimenetet ki lehet értékelni az útvonal-követési hiba (PFE) és a kormányzási elmozdulási zaj (CMN) szűrők felhasználásával is, ha ez előírt.

2.5.2.4.2 Másodszor, ezt a szabvány vevőt használják fel a teljes rendszer műszer-hiba mérésére úgy, hogy a földi berendezést egy antenna hatósugarában, vagy valamilyen más reflexió-mentes környezetben működtetik. Mivel a vevő központosítási hiba elhanyagolhatóvá vált, a mért útvonal-követési hibát (PFE) a földi berendezésnek lehet tulajdonítani. A földi berendezés kormányzási elmozdulási zaját (CMN) úgy kapják meg, hogy az ismert szabvány vevő kormányzási elmozdulási zaj (CMN) ingadozást kivonják a mérések kormányzási elmozdulási zaj ingadozásából. Az egy 10 másodperces mérési időtartam átlagos hibáját kell az útvonal-követési hibának (PFE), míg a különbségi ingadozás négyzetgyökének kétszeresét kell a műszer kormányzási elmozdulási zaj hibának tekinteni.

2.6 Teljesítménysűrűség

2.6.1 *Általános rész*

2.6.1.1 A szög teljesítmény határokra három követelmény került meghatározásra:

a) a szög egyszeri-letapogatási vételéhez 14 dB-es jel-zaj arány (SNR) szükséges a sugárnyaláb burkológörbe szűrőn mérve (azaz a video jel-zaj arány);

b) a szög kormányzási elmozdulási zajt (CMN) meghatározott határértékeken belül kell tartani;

c) a differenciális fáziseltolásos kódolású (DPSK) adattovábbításnak legalább 72 százalékos valószínűségűnek kell lenni a fedésterület határvonalainál.

2.6.1.2 A kormányzási elmozdulási zaj (CMN) forrása a 37 km-nél (20 tenger mérföld) elsődlegesen a vevő belső termikus zaja. A zaj által létrehozott hibát (d) a következőkkel lehet kiszámítani:

$$d\theta = \frac{\theta_{BW}}{2\left(\sqrt{SNR}\ \sqrt{g}\right)}$$

$$g = \frac{\text{Funkció mintavételi sebesség}}{2\ (\text{Szűrő zaj sávszélesség})}$$

ahol Θ_{BW} az antenna sugárnyaláb szélesség fokokban és a *g* a funkció mintavételi sebességének a vevő kimeneti szűrő zaj sávszélességéhez viszonyított aránya. Egy egy-pólusú szűrőnél a zaj sávszélesség a 3 dB-es sávszélesség $\pi/2$-szerese. Ez a kifejezés a kormányzási elmozdulási zajnak (CMN) a földi antenna sugárnyaláb szélességétől és a mintavételi sebességtől való függését tükrözi.

2.6.2 *A rendszer teljesítmény szükséglete*

2.6.2.1 A rendszer teljesítmény szükségletét a G-1. táblázat mutatja be. A 3. Fejezet 3.11.4.10.1 pontjában meghatározott teljesítménysűrűség a G-1. táblázatban a légijármű antennájáról meghatározott jel teljesítményre van vonatkoztatva, a következő összefüggéssel:

$$\text{Teljesítmény az izotróp antennára (dBm)} = \text{Teljesítménysűrűség (dBW/m}^2\text{)} - 5{,}5$$

2.6.2.2 A szög funkció mérése alapfeltételként egy 26 kHz-es sugárnyaláb burkológörbe szűrő sávszélességet fogad el. A fenti 2.6.1 pontban megadott videó (jel-zaj viszony) a következők szerint kapcsolatos a középfrekvenciás (KF) jel-zaj viszonnyal:

$$\text{Jel-zaj viszony (Videó)} = \text{Jel-zaj viszony (KF)} + 10 \log \left[\frac{\text{KF zaj sávszélesség}}{\text{Videó zaj sávszélesség}}\right]$$

2.6.2.3 A differenciális fáziseltolásos kódolás bevezető jelszakaszának elemzésénél alapfeltételként elfogadott: 1) a vivőhullámot visszaállító fázis szinkronizáló hurok fedélzeti vevő alkalmazása; és 2) az, hogy a vevő bevezető jelszakasz dekódolója minden olyan bevezető jelszakaszt visszautasítson, amely nem elégíti ki a Barker kódot, vagy nincs bevezető jelszakasz paritás ellenőrzése.

2.6.2.4 A G-1. táblázatnak az a)-tól az e)-ig terjedő alpontjai a légijármű helyzetére, vagy az időjárásra vonatkozó funkciók, és így rendszertelen előfordulású esetnek tekintett. Ez az, amiért csak nagyon ritka esetekben fogják egyidejűleg elérni a legkedvezőtlenebb értéküket. Ennek megfelelően ezeket a veszteségeket véletlenszerű változóknak lehet tekinteni, és a négyzetes középértéküket kell veszteség összetevőként venni.

2.6.2.5 Az automatikus leszállási üzemeltetések alátámasztásához a 3. Fejezet 3.11.4.10.1 pontjában megközelítési oldalszög szög jelekre meghatározottaknál nagyobb teljesítménysűrűségre van szükség az alsó fedésterületi határvonalon a futópálya felülete feletti kormányzási elmozdulási zajnak a 0,04 fokra történő csökkentéséhez. Szabályszerűen, ez a kiegészítő teljesítménysűrűség természetes következményként fog jelentkezni amiatt, hogy ugyanazon adót használják a letapogató sugárnyaláb és a differenciális fáziseltolásos kódolás biztosítására, és figyelembe vesznek olyan egyéb teljesítmény feleslegeket, mint a rendelkezésre álló légijármű antenna nyereség, a terjedési veszteségek, a fedésterületi veszteségek a széles szögek esetében és az eső miatti veszteség, amelyeket - legalábbis részben - a futópálya körzetében ki lehet hagyni a számításból (lásd a G-1. táblázatot).

2.6.3 *Fedélzeti teljesítmény szükséglet*

2.6.3.1 A G-2. táblázat a fedélzeti teljesítmény szükséglet egy olyan példáját mutatja be, amelyet a teljesítménysűrűség szabványok kidolgozásához használtak fel.

2.7 Adat alkalmazások

2.7.1 *Alapadat.* A 3. Fejezet 3.11.4.8.2.1 pontjában meghatározott alapadatok arra a célra biztosítottak, hogy lehetővé tegyék a légijármű fedélzeti vevők részére a különféle földi berendezés kialakítások letapogató sugárnyaláb információinak feldolgozását, és hogy úgy szabályozzák a kimenő adatokat, hogy azok értelmezhetőek legyenek a légijármű vezetője és a fedélzeti rendszer számára. Az adatfunkciók még arra is használatosak, hogy kiegészítő információkat biztosítsanak (például állomás azonosítást és berendezés állapotot) a légijárművezető, vagy a fedélzeti rendszer részére.

2.7.2 *Kiegészítő adatok*

2.7.2.1 A 3. Fejezet 3.11.4.8.3.1 és 3.11.4.8.3.2 pontjában meghatározott kiegészítő adatok arra a célra biztosítottak, hogy digitálisan elküldjék felfelé a következő információ típusokat:

a) *A földi berendezés telepítési geometriáját leíró adatok.* Ezek az A1-A4 szavakban és a B40-B54 szavak egy részében kerülnek továbbításra.

b) *Az MLS / RNAV üzemeltetéseket alátámasztó adatok.* Ezek a B1-B39 szavakban kerülnek továbbításra.

c) *Üzemeltetési tájékoztatási adatok.* Ezek a B55-B64 szavakban kerülnek továbbításra.
2.7.2.2 A kiegészítő adat szavak átviteli sebessége a következő feltételeken alapszik:

a) Azokat az adatokat, amelyeknek a dekódolása az MLS fedésterületére való kilépéshez viszonyított hat másodpercen belül szükséges, az adások közötti 1 másodperces maximális időközzel kell továbbítani (lásd a 7.3.3.1.1 pontot).

b) Azokat az adatokat, amelyek egy szándékolt üzemeltetéshez szükségesek, de nem kell az, hogy hat másodpercen belül dekódolásra kerüljenek, az adások közötti 2 másodperces maximális időközzel kell továbbítani. Ez a sebesség lehetővé fogja tenni az adat elvesztése esetén a riasztás létrehozását 6 másodpercen belül.

c) Az üzemeltetési tájékoztatási adatokat az adások közötti 10 másodperces maximális időközzel kell továbbítani. Ez lehetővé fogja tenni az adat elvesztése esetén a riasztás létrehozását 30 másodpercen belül.

2.7.3 *Az MLS / RNAV , a B1-től a B39-ig terjedő adatszavak alkalmazása*

2.7.3.1 A B1-től a B39-ig terjedő, az MLS / RNAV üzemeltetések lehetővé tételére kijelölt kiegészítő adatszavakban foglalt adatok csak az MLS adatszavakon belüli adattartalom felhasználását támasztják alá. Abból a célból, hogy a számított középvonalas megközelítések mind az elsődleges, mind a másodlagos futópályákra, valamint hogy az íves megközelítések és indulások, továbbá a megszakított megközelítések alátámasztásra kerüljenek, ezek az adatok az eljárás típusára (megközelítés, vagy indulás), az eljárás nevére, a futópályára és az útvonal-pontokra vonatkozó információkat foglalják magukba.

2.7.3.2 A megközelítési oldalszöggel és a hátsó irányszektorral együtt továbbított adatok külön vannak választva. Ez például azt jelenti, hogy mindegyiknek lesz egy önálló Ciklikus Redundancia Ellenőrzése (CRC), és a légijármű fedélzeti berendezések függetlenül fogják dekódolni azokat. Az egy adott MLS / RNAV eljárásra vonatkozó adatok abba a fedésterületi részbe kerülnek kisugárzásra, ahol az eljárás megkezdődik. Szabályszerűen ez azt jelenti, hogy a megközelítési és a megszakított megközelítési adatok a megközelítési oldalszög területre lesznek kisugározva, és az indulási adatokat a hátsó irányszektor berendezés fogja továbbítani. Azonban azokat az útvonal-pontokat, amelyek egyaránt tartoznak a megközelítéshez, megszakított megközelítéshez, vagy az induláshoz, le lehet adni, vagy az oldalszög, vagy a hátsó irányszektor fedésterületre. Például, egy indulási eljárás megkezdődhet az oldalszög fedésterületen, és ennek megfelelően az adatot le lehet adni a megközelítési oldalszöggel. Ha az eljárás egy közös fedésterületi részen belül kezdődik, akkor a kapcsolódó adatokat le lehet adni csak az egyik területre, kivéve azt, ahol az üzemeltetési körülmények másképpen szabják meg.

2.7.3.3 Az eljárásokat útvonal-pontok sorozata határozza meg. Az útvonal-pontokat egy Descartes-féle derékszögű koordináta rendszer szerint határozzák meg X, Y és Z koordinátákkal, amelyeknek a kiinduló pontja az MLS alappont. A koordináta rendszert a
G-13. ábra mutatja be.

2.7.3.4 Az útvonal-pontok közötti szakaszok vagy egyenesek, vagy ívesek. Az íves szakaszok két útvonal-pontot összekötő körívként kerülnek meghatározásra úgy, ahogy azt a G-14. számú ábra bemutatja. A kör íve mindig a megelőző és a következő – egyenes, vagy köríves - szakasz érintője. Egy megközelítési eljárás végső megközelítési szakaszának és a kiindulási útvonal-pontra mutató szakaszának, illetve az indulási eljárás, vagy a megszakított megközelítési eljárás utolsó átrepült útvonal-pontjától meghosszabbított szakasznak mindig egyenesnek kell lenni. Vannak az egyenes szakaszoknak, vagy a köríves szakaszok érintőinek meghosszabbított szakaszai. Ezek az egyenes szakaszok nem igényelnek szükségszerűen útvonal-pontot a fedésterület határvonalán, így az ilyen útvonal-pontokat "meg lehet takarítani".

2.7.3.5 Bármilyen típusú eljárásban a kódolás a futópálya küszöbétől legtávolabb lévő ponttól kezdődik, és a futópályához legközelebb lévő útvonal-pontnál fejeződik be. A megközelítési eljárás összes útvonal-pontját kódolni kell, mielőtt bármilyen megszakított megközelítési útvonal-pont, vagy indulási útvonal-pont kódolásra kerülne. Ez a szabály leegyszerűsíti a dekódolást azáltal, hogy különválasztja a megközelítéshez tartozó útvonal-pontokat a többi útvonal-ponttól. Több eljárás megosztottan használhat fel egy, vagy több útvonal-pontot. Amikor ez a helyzet fennáll, akkor megvalósítható az, hogy az az információ csak egyszer kerül leadásra. A megosztottan felhasznált útvonal-pontnak a megközelítési eljárás utolsó pontjainak és a megszakított megközelítési, vagy indulási eljárás kiindulási pontjainak kell lenni. A megközelítések, a megszakított megközelítések és az indulások felhasználhatnak megosztott adatokat, feltéve, hogy az adatok ugyanabba a fedésterületi szektorba kerülnek kisugárzásra. Amikor egy útvonal-pont egy olyan eljárással kerül megosztottan felhasználásra, amely előzetesen meghatározásra került az adatbázisban, akkor azt egy útvonal-pontot követő útvonal-pont mutatóval kell jelezni. Ez az útvonal-pont mutató adja meg az első megosztottan használt útvonal-pontnak az adatbázisban lévő helyét.

2.7.3.6 Az útvonal-pont mutató az a számszerű érték, amely azt a folytatólagos sorrendet mutatja meg, amelynek megfelelően az útvonal-pont az adatbázisban jegyzékbe van véve. A kódolásban ez arra használatos, hogy jelezze, az útvonal-pontok az eljárásban hol helyezkednek el. Az eljárás leírásában nulla útvonal-pont mutató azt jelzi, hogy az egy számított középvonalas eljárás, ahol nincsenek útvonal-pontok biztosítva.

2.7.3.7 Jóllehet, az útvonal-pontok X, Y és Z koordinátákkal kerülnek meghatározásra, az esetek nagy részében az összes koordináta nem kerül leadásra. Egy, az elsődleges futópálya középvonalán lévő útvonal-pontnak az Y koordinátája nulla. Azt az adatmezőt, amely ezt az értéket határozza meg, el lehet hagyni úgy, hogy az "Y koordináta követő" bitet NULLÁ-ra állítják.

2.7.3.8 Amikor a Z koordináta nem szükséges repülési pálya felépítési adatként, akkor azt meg lehet "takarítani" úgy, hogy ez az érték nem kerül továbbításra. Ezt a "Z koordináta követő" bit NULLÁ-ra állításával lehet jelezni. Ezt a kezdeti megközelítési útvonal-pontokra lehet alkalmazni, a végső megközelítési navigációs pontot megelőző pontokra, ahol az útirány-vezetés még magasság-mérésen alapszik, nem pedig a számított MLS függőleges helyzeten. Ezt alkalmazni lehet még az olyan útvonal-pontokra is, melyek meghatározott Z értékű útvonal-pontok közötti folyamatos süllyedési gradiensű repülési pályán helyezkednek el. Ebben az esetben a fedélzeti berendezés számolja ki a Z koordinátát egy folyamatos süllyedési gradienst figyelembe véve. A megszakított megközelítéseknek és az indulási útvonalaknak a hátsó irányszektor fedésterületen elhelyezkedő útvonal-pontjai ugyancsak a Z koordináta elhagyásának lehetséges pontjai, mivel itt a függőleges útirány-vezetés nem áll rendelkezésre. A hátsó irányszektorban történő alkalmazásnál a Z koordinátát le lehet adni a fedélzeti berendezés általi olyan felhasználásra, amely "megmagyarázza" a légijármű vízszintes helyzetét.
Ez lehetővé teszi azoknak az oldalirányú hibáknak a lecsökkentését, amelyeket az X - Y koordinátákra a ferde távolságnál a kúpos hátsó irányszektor oldalszög értékekre való áttérés vezethet be.

2.7.3.9 Az útvonal-pont koordinátákat követő 3-bites adatmező a következő szakasz / mező azonosítót foglalja magába. Ez az adatelem azt jelzi, hogy az eljárás következő szakasza egyenes, vagy íves, illetve azt, hogy az átrepülendő útvonal-pont az eljárás utolsóként meghatározott pontja, és hogy az eljárás kapcsolódik-e egy meghatározott megközelítéshez, vagy egy másik, egy megszakított megközelítési mutatóval, vagy következő útvonal-pont azonosított eljárás megosztottan használt részéhez. Ez jelzi még azt is, hogy egy futópálya küszöb keresztezési magasság, vagy a látszólagos oldalszög - útvonal-pont távolság adatmező került-e az útvonal-pont meghatározáshoz hozzákapcsolásra.

2.7.3.9.1 Az A-Függelék A-17.sz. táblázatában foglalt azonosítók néhány jellegzetes alkalmazása az alábbiakban kerül megadásra. A jegyzék nem az összes alkalmazást foglalja magába:

a) a 0 és 1 azonosítók akkor használatosak, amikor az eljárás következő útvonal-pontja nem egy megosztottan felhasznált útvonal-pont, vagy egy megosztottan felhasznált útvonal-pont először kódolva;

b) a 2 és 3 azonosítók arra használatosak, hogy az eljárás olyan útvonal-pontjaira utaljanak, amelyek már kódolva volta, és egy másik eljárással megosztottan használatosak. Ezeknek az útvonal-pontoknak a kódolása nem kerül megismétlésre, de a mutató lehetővé teszi az eljárásnak a másik eljárással megosztottan használt útvonal-pontokkal való összekapcsolását;

c) a 4 és 5 azonosítók az elsődleges futópályánál végződő, vagy onnan kezdődő eljárás a következő, az utolsó útvonalpontjához használatosak. Az utolsó útvonal-pont a futópálya küszöbe. Ehhez az útvonal-ponthoz csak a futópálya küszöbének keresztezési magassága van meghatározva, mivel a futópálya küszöbének az MLS alapponthoz viszonyított pontos helyzete a kiegészítő A-szavakban kerül megadásra. A 4 azonosító akkor használatos, amikor az MLS / RNAV megszakított megközelítési útirány-vezetés nem szükséges, és az 5 azonosító akkor, amikor egy "megszakított megközelítési mutató" következik;

d) a 6 és 7 azonosítók bármely eljárás utolsó útvonal-pontja jelzésére használatosak, kivéve a fenti c) pontban leírtakat. Az elsődleges futópályánál ezek az azonosítók akkor használatosak, amikor az utolsó útvonal-pont X, Y és Z koordinátáinak meghatározása teljes egészében szükséges. Ezek az azonosítók használatosak még a másodlagos futópályákhoz és a helikopter leszálló helyekhez. A 6 azonosító akkor használatos, amikor nem következik megszakított megközelítés és a 7 azonosító akkor, amikor megszakított megközelítés következik; és

e) az 5 és 7 azonosítókat nem lehet a megszakított megközelítéseknél az indulásoknál alkalmazni.

2.7.3.10 A következő konvenció a további MLS alap- és kiegészítő adatokra az, hogy az összes, az adatbázisban kódolt digitális adatot elsőként a legkisebb helyiértékű bitet leadva kell leadni, és az előjel bitet a legnagyobb helyiértékű bitként kell továbbítani, az EGY-el jelölve a negatív értéket. Figyelembe kell venni azt, hogy a kiegészítő adatszavak címei használatosak az utolsó megközelítési oldalszög adatbázis szó jelzésére, és az első hátsó irányszektor oldalszög adatbázis szó a legnagyobb helyiértékű bit elsőként történő leadásával történik.

2.7.4 *Példa az MLS / RNAV adatszavak alkalmazására*

2.7.4.1 A következő pontok egy példát adnak a B1 - B39 kiegészítő adatszavakba foglalt MLS / RNAV adatszavak adat elosztási eljárására. A megközelítési és indulási eljárások egy minta elrendezését adjuk meg, valamint annak a folyamatnak a leírását, amellyel a különféle útvonal-pontok és a hozzájuk kapcsolódó eljárás jellemzők értelmezésre és a továbbításhoz összeállításra kerülnek.

2.7.4.2 A G-3. táblázat egy megközelítési, megszakított megközelítési és indulási eljárás sorozatot ír le, két feltételezett futópályára. A G-4. táblázat a G-3. táblázatban jelzett és a G-15. számú ábrán bemutatott minta eljárások útvonal-pont adatait tartalmazza.

2.7.4.3 Mielőtt az eljárási adatokat beillesztenék a B1 - B39 szavakba, először az MLS / RNAV adatok jellemzőit kell megérteni abból a célból, hogy optimálisan használják fel a rendelkezésre álló számú adatszót. A G-3. és G-4. táblázatban lévő adat sorozatnál a következő sajátos jellemzőket kell megjegyezni: a KASEL és NELSO eljárások megosztottan használják ugyanazokat az útvonal-pontokat, azaz az 1.számút (WP 1) és a 2.számút (WP 2); a KASEL és NELSO eljárások kapcsolódnak egy megszakított megközelítési eljáráshoz; a SEMOR eljárás egy másodlagos futópálya megközelítése; a LAWSO egy indulási eljárás és a hátsó irányszektor fedésterületére lesz kisugározva; az összes, a precíziós végső megközelítési navigációs ponton (PFAF) kívül eső útvonalpontnál nem szükséges a Z koordináta továbbítása; az Y koordináta nem kerül majd továbbításra több útvonal-pontnál, azoknál, amelyek az elsődleges futópálya meghosszabbított középvonalán helyezkednek el.

2.7.4.4 Az A-Függelék A-15. táblázatában meghatározott B1 adatszó a megközelítési oldalszög fedésterületi szektorba kisugározandó MLS / RNAV adatok szerkezetét határozza meg. Ez a szó magába foglalja még a megközelítési oldalszög ciklikus redundancia ellenőrzési kódját is. A megközelítési oldalszög szektorba kisugározandó eljárások száma 3. Ezt a G-3. táblázatból lehet meghatározni. Az utolsó megközelítési oldalszög MLS / RNAV adatszó adatszó címzését azután kell meghatározni, miután a teljes sorozat a formátumba beillesztésre került. Ebben az esetben az utolsó szó címzése a B11. A ciklikus redundancia ellenőrzési (CRC) kód úgy került kiszámításra, ahogy az az A-15. táblázat 3. Megjegyzésében leírásra került. A B42 és a B43 szavak nem kerülnek továbbításra, úgy, hogy a vonatkozó biteket NULLÁ-ra kell állítani. Az A4 szó leadásra kerül, úgy, hogy a vonatkozó biteket EGY-re kell állítani. A B1 adatszó kódolását a G-5. táblázat mutatja be.

2.7.4.5 Az A-Függelék A-15. táblázatában meghatározott B39 adatszó a hátsó irányszektor fedésterületi szektorba kisugározandó MLS / RNAV adatok szerkezetét határozza meg. Ez a szó magába foglalja még a hátsó irányszektor ciklikus redundancia ellenőrzési kódját (CRC) is. A hátsó irányszektorba kisugározandó eljárások száma 1. Az első hátsó irányszektor MLS / RNAV adatszó

adatszó-címzését azután kell meghatározni, miután a teljes sorozat a formátumba beillesztésre került. Ebben az esetben az első szó címzése a B36.
A ciklikus redundancia ellenőrzési (CRC) kód úgy került kiszámításra, ahogy az az A-15. táblázat 3. Megjegyzésében leírásra került. A B43 szó nem kerül továbbításra, úgy, hogy a vonatkozó biteket NULLÁ-ra kell állítani. A hátsó irányszektor térkép / ciklikus redundancia ellenőrző jelzés bit EGY-re van állítva, annak jelzésére, hogy ez a térkép / ciklikus redundancia ellenőrző szó. A B39 adatszó kódolását a G-5. táblázat mutatja be.

2.7.4.6 Az A-Függelék A-15. táblázatában meghatározott eljárás leíró szavak az összes megközelítési és indulási eljárás számára kerültek meghatározásra. A megszakított megközelítési eljárások az adat formátumban a megközelítési eljárásokkal vannak összekapcsolva, ennélfogva nem igényelnek eljárás leírót. A minta adat sorozat eljárás leíró szavait a G-6. táblázat mutatja be. Meg kell jegyezni azt, hogy az eljárás leíró adatszavakat nem lehet addig teljes egészükben meghatározni, amíg az útvonal-pont adatok tényleges kijelölése be nem fejeződik, mivel szükség van az egyes eljárásokhoz kapcsolódó "első útvonal-pont mutatóra". Ez az adatelem az első útvonal-pont az eljárás egymás után következő sorozatában. A mutató úgy kerül összeállításra, ahogy az a fenti 2.7.3.6 pontban leírásra került. Meg kell jegyezni azt, hogy az eljárás név "érvényesség jelző" (lásd a G-4. táblázatot) az eljárás változat száma és az értéke 1-től 9-ig terjed.

2.7.4.7 Az útvonal-pont adat kiosztási folyamatnak az A-Függelék A-15., A-16. és A-17. táblázatában leírtaknak kell megfelelni. A G-7. táblázat mutatja be a minta adat sorozat kiosztását. A bevezető jelszakaszok, a címek és a paritás bitek kihagyásra kerültek a táblázatból. Közvetlenül a megközelítési eljárás leíró szavak után az adatszóval kezdve, az első eljárás első útvonal-pontja kerül kiosztásra. A minta adat sorozatnál ez azt jelenti, hogy a B5 adatszó, útvonal-pont adattal. A következő lépés az adatnak a megfelelő formátumba való beillesztése. Az eljárások adatai mindig a kiindulási útvonal-pont X koordinátájával kezdődnek. Az adatbázis szerkezete lehetővé teszi azt, hogy az egyedi adatelemek átfedjenek a kiegészítő adatszavak között. Például, a KASEL eljárás 3. útvonal-pontja (WP 3) X koordinátájának az első 14 bitje a B5 szóban kerül leadásra. Az utolsó bit a B6-ban van továbbítva.

2.7.4.7.1 Az útvonal-pont koordináta legkisebb helyiértékű bitjének súlyozása miatt a kódolt útvonal-pont koordinátát kerekíteni kell. Az a kívánatos, hogy olyan eredmény kerüljön elérésre, ami a lehető legközelebb van a tényleges útvonal-pont értékéhez. Az ilyen kerekítést általában a legkisebb helyértékű bit súlyozása felének a tényleges értékhez való hozzáadásával és ezután az eredménynek egészszámmal való elosztásával hajtjuk végre. Például, a KASEL eljárás 2. útvonalpontjának (WP 2) az X koordinátája 6 556 m (tényleges). A kódolt bináris érték 2 561 lesz, mivel

$$Integer\left[\frac{\left(|6\ 556| + \frac{2.56}{2}\right)}{2.56}\right] = 2\ 561$$

A negatív számoknál az előjel bitet kell áthozni a számításba.

2.7.4.8 Az X koordináta után az "Y koordináta követő" bit következik. Ezt a bitet a KASEL 2. útvonal-pontra (WP 2) és az 1. útvonal-pontra (WP 1) - ahogy azt a G-7. táblázat mutatja - nullára kell állítani, és az Y koordináta nem kerül továbbításra. Ahogy az a KASEL 3. útvonal-pontnál (WP 3) bemutatásra kerül, az Y koordinátára szükség van, és az "Y koordináta követő" bit után leadásra kerül.
2.7.4.9 Az "Y koordináta követő" bit kódolásától függően az Y koordináta információk után a "Z koordináta követő" bit kerül kódolásra. A KASEL eljárás 4. útvonal-pontjánál (WP 4) nem szükséges a Z koordináta, mivel az a precíziós végső megközelítési navigációs pont
/PFAF/ előtt van. A Z koordináta ugyancsak nem szükséges a 2. útvonal-ponthoz (WP 2), mivel az egy folyamatos siklópályán van a 3. útvonal-pont (WP 3) és az 1. útvonal-pont (WP 1) között. Ahogy az látható, a KASEL 3. útvonalpontnál (WP 3) a Z koordinátára szükség van, és a "Z koordináta követő" bit után leadásra kerül.

2.7.4.10 A következő szakasz / adatmező azonosító az A-Függelék A-17. táblázatának megfelelően kerül kiosztásra. A KASEL eljárás 2. útvonal-pontját (WP 2) követő azonosítónál az 5. érték azt jelzi, hogy a küszöb útvonal-pont magassága a következőkben lesz leadva, a megszakított megközelítési eljárás útvonal-pont mutatóját követően. A NELSO eljárásnál, mivel az utolsó két útvonal-pontot megosztottan használja fel a KASEL eljárással, a 3. útvonal-pontot (WP 3) követő azonosítójának az értéke 3, ami azt jelzi, hogy a következő útvonal-pont mutatója a következőkben lesz leadva. Ebben az esetben a mutató 3. és ez a KASEL eljárás 2. útvonal-pontjára (WP 2) mutat. A megszakított megközelítési eljárásnál az azonosító 6-ra van állítva, ami azt jelzi, hogy ez az eljárás utolsó útvonal-pontja. A másodlagos futópálya eljárásánál, a SEMOR-nál az azonosító ugyancsak 6-ra van állítva. Ebben az esetben azonban ez azt jelzi, hogy a látszólagos oldalszög - útvonal-pont távolság következik.

2.7.4.11 A G-8. táblázat mutatja be az indulási eljárás útvonal-pontjainak kiosztását. Az indulási adatok a B36 szóval, az eljárás leírással kezdődnek. Az útvonal-pont adatok a B37 szóban kezdődnek. Az indulási adatok ugyanannak a módszernek az alkalmazásával kerülnek kiosztásra, mint a megközelítési adatok.

2.7.4.12. Miután az adatbázis teljes egészében kiosztásra került, a ciklikus redundancia ellenőrző (CRC) értékeket lehet kiszámítani a B1 - B39 és az egyéb szükséges adatelemek felhasználásával. A G-9. táblázat mutatja be ennek a számolásnak egy olyan minta adat sorozatra kapott eredményeit, amelyek magukba foglalják a kiegészítő adat A szavakat, a B6 alapszót és a B40 - B41 kiegészítő szavakat.

2.8 A szomszédos csatorna zavarás figyelembevétele

2.8.1 A szabvány úgy került megszerkesztésre, hogy legalább egy 5 dB-es tűréssel számoltak a kisugárzott teljesítmény ingadozásnál a minimális teljesítménysűrűség előírások felett. Az interferencia előírások a legrosszabb esetű antenna sugárnyaláb szélesség kombináción, adatátviteli sebességen és nem-kívánt zavaró szinkronizáláson alapulnak.

3. Földi berendezés

3.1 A letapogató sugárnyaláb formája

3.1.1 Az oldalszög letapogató sugárnyaláb burkológörbéje az antenna irányítási vonalon és a magassági szög letapogató sugárnyaláb burkológörbéje az elsőbbségi magassági szögnél - ahogy azt egy szabvány vevő detektálja - meg kell, hogy egyezzen a G-16. ábrán meghatározott határértékekkel nagy jel-zaj viszonyú körülmények és elhanyagolható többutas terjedés esetén (azaz egy, az antenna tartományon belüli vizsgálat során). A -10 dB-es szimmetria a pontossági teljesítményre vonatkozóan a berendezés tervezésnél nem szükségszerűen elvárt.

3.2 A letapogató sugárnyaláb oldalszirommal

3.2.1 *Előírt teljesítmény adatok.* Az antenna oldalszirom tervezésnek a következő két feltételt kell kielégíteni: 1) a dinamikus oldalszirom szint nem akadályozhatja meg azt, hogy a fedélzeti vevő befogja és kövesse a fő sugárnyalábot. A kielégítő teljesítményt nem lehet biztosítani akkor, ha a dinamikus oldalszirmok a mínusz 10 dB-es szint felett maradnak; 2) a tényleges oldalszirom szint összeegyeztethető a rendszerhiba határral.

3.2.2 A tényleges oldalszirom szint (P_{ESL}) a dinamikus oldalszirom szintre (P_{DYN}) vonatkoztatva:

$$P_{ESL} = K\, P_{DYN}$$

ahol *K* az a csökkentő tényező, amely az antenna kivitelezésétől függ.
A csökkentő tényező a következőktől függő lehet:

a) az irányított antenna elemek rendszerétől, amelyek csökkentik a többutas jelszintet a fedésterületre viszonyítva;

b) a dinamikus oldalszirmok szabálytalanságának fokától.

Megjegyzés. - A dinamikus oldalszirmoknak kicsi a fontossága akkor, amikor a mért dinamikus oldalszirom szintek kisebbek a meghatározott tényleges oldalszirom szinteknél.

3.2.3 Az oldalszög antenna oldalszirmaiból eredő oldalirányú többutas visszaverődés és a magassági szög antenna oldalszirmaiból eredő földi többutas visszaverődés zavarhatja a fő sugárnyalábot és szögbeli hibákat hozhat létre. Annak biztosítására, hogy az antenna oldalszirmok által létrehozott dv hiba a terjedési hibákon belül legyen, a megkívánt tényleges oldalszirom szintet, ESL, a következők szerint lehet felbecsülni:

$$P_{ESL} = \frac{d\theta}{\theta_{BW} P_R P_{MA}}$$

ahol a P_R a többutas akadály visszaverődési együttható, Θ_{BW} a földi antenna sugárnyaláb szélessége és P_{MA} az elmozdulás átlagoló tényező.

3.2.4 Az elmozdulás átlagoló tényező a jellemző többutas terjedés geometriájától, a légijármű sebességétől, a funkció adatsebességétől és a kimeneti szűrő sávszélességétől függ. Amikor a többutas terjedés geometriájának és a légijármű sebességének kombinációja olyan, hogy a többutas lengési frekvencia 1,6 Hz-nél nagyobb, akkor az elmozdulási tényező a következő:

$$P_{MA} = \sqrt{\frac{2\ (\text{kimeneti szűrő zaj-sávszélesség})}{\text{Funkció adatsebesség}}}$$

3.2.5 Ezt a tényezőt tovább lehet csökkenteni a magasabb többutas terjedési lengési frekvenciáknál, ahol a többutas terjedés által létrehozott sugárnyaláb torzulások nem összefüggőek a TO és FRO letapogatások közötti időközben.

3.3 Megközelítési magassági szög antenna karakterisztikája

3.3.1 Amikor a többutas terjedés hatásának korlátozása szükséges, akkor a megközelítési magassági szög antenna vízszintes sugárzási karakterisztika fokozatos jel utóelnyomása szükséges az antenna-irányítási vonaltól távolodva. Jellemzően a megközelítési magassági antenna vízszintes sugárzási karakterisztikáját az antenna-irányítási vonaltól 20 fokra 3 dB-el és az antenna-irányítási vonaltól 40 fokra 6 dB-el kell csökkenteni. A tényleges többutas terjedési körülményektől függően a vízszintes sugárzási karakterisztika több, vagy kevesebb utóelnyomást igényelhet.

3.4 Megközelítési / hátsó irányszektor oldalszög csatornák

3.4.1 Amikor egy futópályához mindkét megközelítési irányra MLS-t telepítenek, és a berendezés nincs a megközelítésre használatban, akkor hátsó irányszektor oldalszög adóként üzemeltethető. Amikor kívánatos az, hogy eltérő csatornát jelöljenek ki minden egyes futópálya irányra, akkor szükségszerűen az oldalszög adó egységek különböző frekvenciákon lesznek üzemeltetve az üzemeltetési módtól függően – megközelítési, vagy hátsó irányszektor oldalszög. Figyelemmel kell lenni a csatorna kiosztásnál arra, hogy a két frekvencia elég közel legyen azért, hogy az oldalszög antenna függőleges sugárzási karakterisztikájának bármilyen mechanikai szabályozása elkerülhető legyen akkor, amikor a megközelítési irányt átfordítják.

3.4.2 A frekvencia elkülönítést úgy kell korlátozni, hogy a hátsó irányszektorra a sugárzási karakterisztika erősítési tényezőjének vesztesége (optimális megközelítési értékhez viszonyítva) képes legyen "befogadni" azokat az adó teljesítmény határértékeket, amelyek a G-1. táblázatban a hátsó irányszektor funkcióra megadásra kerültek.

4. A telepítésre vonatkozó megfontolások

4.1 MLS / ILS együttes telepítés

4.1.1 *Az MLS magassági szög antennája*

4.1.1.1 *Bevezetés*

4.1.1.1.1 Amikor az MLS magassági szög adó antennáját együtt telepítik egy ILS siklópálya adóval, akkor egy döntés sorozatot kell hozni ahhoz, hogy a magassági szög adó antennájának elhelyezését meghatározzák. A telepítési feltételek úgy kerültek kidolgozásra, hogy azok az MLS magassági szög adó berendezésnek az ILS siklópálya adó jeleire való hatások minimálisra csökkentésén alapulnak. A feltételek a térbeli jellel, az üzemeltetésnél a kritikus területekkel és az akadálymentességi megfontolásokkal együtt befolyással lesznek a magassági szög antenna végső elhelyezésére.

4.1.1.1.2 A cél az, hogy a magassági szög adó antenna telepítésének egy megközelítő területével kezdjenek, és azután csökkentsék le azt a területet az adott berendezés optimális elhelyezésére. Ezt a célt úgy lehet elérni, hogy végighaladnak a tények és figyelembe veendők sorozatán. A döntéshozó folyamat egy logikai folyamatábraként a G-17. számú ábrán kerül bemutatásra.
Ezeknek az útmutató vonalaknak nem az a céljuk, hogy egy mindent magukba foglaló MLS telepítési kézikönyvként szolgáljanak, hanem csak arra szolgálnak, hogy kiegészítő útmutatásokat adjanak akkor, amikor az MLS-nek az ILS-el való együttes telepítése szükséges.

4.1.1.1.3 A G-17. ábrára hivatkozva a szakasz számok a három telepítési geometria egyikének felelnek meg, mint például az alábbi 4.1.1.2 "a magassági szög antennának a siklópálya adó és a futópálya közötti telepítése", stb. Minden egyes blokk előtt a számok arra a meghatározott paragrafusra utalnak, amelyek a G-17. ábra alátámasztó szövegei. Ez a paragrafus adja meg annak / azoknak a tényező(k)nek a részletesebb leírását, amelyeket annál a lépésnél meg kell fontolni.

4.1.1.1.4 A magassági szög adó antenna telepítésének két általános területét a G-18. számú ábra mutatja be. A siklópálya adó elhelyezésétől függően vagy az egyik, vagy a másik terület nem áll fenn. Azonkívül ezeknek a területeknek már a figyelembevételüket megelőzően ki kell elégíteni a térbeli jel követelményeket.

4.1.1.2 *A magassági szög adó antennának siklópálya adó és a futópálya közötti telepítése*

4.1.1.2.1 A magassági szög adó antenna hátrafelé elhelyezése (a futópálya küszöbtől) az MLS megközelítési vonatkozási pont (ARD) magasságától függ. Az MLS megközelítési vonatkozási pontnak (ARD) ki kell elégíteni a 3. Fejezet 3.11.4.9.1 pontjában meghatározott követelményeket. A magassági szög adó antenna hátrafelé elhelyezését a következő egyenlettel lehet meghatározni (lásd a G-19. sz. ábrát):

$$SB = \frac{ARDH - RPCH}{\tan\theta} \geq \frac{15 - RPCH}{\tan\theta}$$

ahol:

az összes távolság méterben mért;

SB a magassági szög antenna fázis középpontjának hátrafelé való elhelyezési távolsága a futópálya küszöbétől a futópálya középvonalával párhuzamosan;

RPCH a magassági szög antenna fázis középpontjának relatív magassága a futópálya felületének a küszöbnél lévő szintjével összehasonlítva. (Ez magában foglalja a magassági szög antenna fázis középpontjának a magasságát és a terep magassági különbséget a futópálya küszöbe és a magassági szög antenna helyszíne között.);

ARDH a kívánt MLS megközelítési vonatkozási pont magasság; és a minimális siklópálya; és

Θ a minimális siklópályaszög.

4.1.1.2.2 A magassági szög antenna kúpos koordináta rendszere és a futópálya középvonalától való eltolt (ordináta) helyzete fogja létrehozni azt a minimális magassági szög útirány-vezetést, ami a megközelítési referencia pont felett van. A 3. Fejezet 3.11.5.3.5.2.2 pontjának ajánlását figyelembe véve az eltolt helyzetet a következő egyenlettel lehet korlátozni:

$$(OS)^2 + (SB)^2 \leq \left[\frac{(18 - RPCH)}{\tan\theta}\right]^2$$

ahol:
az összes távolság méterben mért; és

OS az eltolási távolság a magassági szög antenna fázis középpontja és a futópálya középvonalát magába foglaló függőleges sík között (lásd a G-19. számú ábrát).

4.1.1.2.3 Ezenfelül az MLS megközelítési vonatkozási pontnak egy méteren belül egybe kell esni az ILS vonatkozási ponttal, ahogy az a 3. Fejezet 3.11.5.3.5.3 pontjában meghatározásra került. Ez a következő egyenletben megadva:

$$\frac{RDH - 1 - RPCH}{\tan\theta} \leq SB \leq \frac{RDH + 1 - RPCH}{\tan\theta}$$

ahol:
az összes távolság méterben mért; és

RDH az ILS vonatkozási pont magassága.

4.1.1.2.4 A G-18. ábra 1. Területe átlós határvonalának meghatározásához két tényezőt kell számításba venni. Az első az, hogy a magassági szög antenna nem nyúlhat be abba a területbe, amelyen keresztül a Fresnel közeltér húzódik az ILS siklópálya migrációjához a megközelítés során. Általában ezt a követelményt úgy lehet elérni, hogy a magassági szög antennát az átlós vonalnak a futópálya oldala felőli részén túl, a siklópálya antenna oszlopa és a futópálya küszöbnél lévő középvonala között helyezik el. A G-18. ábrán lévő értéke a siklópálya antenna oszlopának a futópálya küszöbénél lévő középvonalához viszonyított helyzetétől függ. A második tényező az, hogy a minimálisra csökkentsék a siklópálya antenna sugárzási karakterisztikájának az oldalirányú "behatolási mélységét" (lásd az alábbi 4.1.1.3.2 pontot). Azonban erre a magassági szög antenna területre a második tényező kielégítése kívánatos, de nem elengedhetetlen.

4.1.1.2.5 Miután a fenti követelményekre alapozva meghatározták a magassági szög antenna elhelyezésének elfogadható távolságát, a magassági szög antenna minimális oldalirányú eltolt helyzetét (ordináta) kell meghatározni, az Annex 14 4. Fejezetében megadott akadálykorlátozási követelmények szerint.

4.1.1.2.6 Amikor az csak lehetséges, a magassági szög antenna helyzetét úgy kell szabályozni, hogy a minimálisra csökkentsék a magassági szög antenna kritikus területének a repülési üzemeltetésekre gyakorolt hatását. Továbbá, az lenne a kívánatos, hogy a magassági szög antenna elhelyezését olymódon válasszák meg, ami a maximálissá teszi az MLS magassági szög antenna kritikus területének és az ILS siklópálya adó kritikus területének egybeesését. Ez az egybeesés a minimálisra fogja csökkenteni az összekapcsolt kritikus területek "megnagyobbodását". Annak szükségessége miatt, hogy a magassági szög antennát a siklópálya adó antenna előtt kell elhelyezni, szabályszerűen a magassági szög antennát a siklópálya adó kritikus területére kell elhelyezni. A magassági szög antenna kritikus területet lásd a következőkben, a 4.3 pont alatti szakaszban. A siklópálya adó kritikus területének leírását lásd a "C"- Melléklet 2.1.10 pontja alatti szakaszban.

4.1.1.2.7 Miután a magassági szög antenna helye megállapításra került, a magassági szög antenna felügyelő egységének elhelyezését kell megtalálni. A magassági szög jelet úgy kell megfigyelni, ahogy az a korábbi 2.4.3 pontban meghatározásra került. A magassági
szög földi felügyelő egységének magassága a minimális siklópálya szög egységet alkotó felügyelő egységétől és az akadálymentességi követelménytől függ. A következő megfontolandó tényezők nyújthatnak segítséget a felügyelő egység elhelyezésének meghatározásához:

a) Az a kívánatos, hogy a földi felügyelő egység olyan közel legyen a távoltérhez, amennyire az gyakorlatilag csak megvalósítható azért, hogy a minimálisra csökkenjen a közeltéri hatás a felügyelő rendszerben.
Azonban ezt a távolságot korlátozni kell azért, hogy az antenna és a földi felügyelő egység közötti jármű és légijármű forgalom miatti téves riasztásokat elkerüljék.

b) Az a kívánatos, hogy a minimálisra csökkentsék a magassági szög jeleknek a felügyelő egység általi - a végső megközelítési területre ható - blokkolását és torzítását. Ezt úgy lehet elérni, hogy a felügyelő egységet a magassági szög antenna antenna- irányítási vonalától oldalirányban 30 fokig terjedően és 40 métertől (130 láb) 80 méterig (260 láb) terjedő távolságban helyezik el, az adott berendezés felépítésétől függően.

c) A földi felügyelő egységnek az antenna középvonalától oldalirányban való elhelyezését a megfelelő megfigyelési érzékenység fenntartása és a mechanikai stabilitás korlátozza. Nem az a cél, hogyha lehet, akkor a földi felügyelő egység oldalirányú elhelyezése meghaladja a magassági antenna középvonalától mért 30 fokot.

d) A magassági szög földi felügyelő egységét úgy kell elhelyezni, hogy elkerüljék azt, hogy hatással legyen, vagy behatást kapjon az ILS siklópálya földi felügyelő egység/re/től.

4.1.1.3 *A magassági szög antennának a siklópálya adó helyénél nagyobb eltolt oldalirányú távolságban való telepítése*

4.1.1.3.1 Amikor a magassági szög adó antennát a futópálya középvonalától a 130 métertől (430 láb) a 180 méterig (590 láb) terjedő eltolt oldaltávolságban helyezik el, akkor az elért megközelítési vonatkozási pont magasság kúpos hatása válik lényegesebbé. A berendezéstől függően a magassági szög antenna hátrafelé elhelyezését lehet, hogy szabályozni kell azért, hogy kielégítse a korábbi 4.1.1.2.1, 4.1.1.2.2 és 4.1.1.2.3 pontokban tárgyalt követelményeket.

4.1.1.3.2 Amikor a magassági szög antennát a futópálya középvonalától a telepített siklópálya adó helyénél nagyobb eltolt oldalirányú távolságnál helyezik el, akkor a magassági szög antenna nem nyúlhat be a siklópálya oldalirányú sugárzási karakterisztikájába. A G-18. számú ábrán a Φ értéke az ott lévő siklópálya adó antenna típusától és a magassági szög adó berendezés fizikai jellemzőitől függ. Általában a "Φ" a siklópálya adó antenna oldalirányú sugárzási karakterisztikájának -10 dB-es pontjait jelzi. A -10 dB-es értéket le lehet csökkenteni -4 dB-re, különösen a siklópálya antennák befogási hatékonyságára, a siklópálya jel minősége felülvizsgálatától függően.

4.1.1.3.3 Miután a fenti követelményekre alapozva meghatározták a magassági szög antenna elhelyezésének elfogadható távolságát, azt a helyet lehet, hogy tovább kell határolni azért, hogy kielégítse az Annex 14 akadálykorlátozási követelményeit, különösképpen a gurulóút - akadály elkülönítési követelményeket.

4.1.1.4 *Alternatívák*

4.1.1.4.1 Ha a magassági szög antennának a siklópálya adó antennával való együttes telepítését nem lehet teljesen megvalósítani, akkor alternatívaként a magassági szög antennát a futópálya ellentétes oldalán lehet elhelyezni.

4.1.2 *MLS oldalszög antenna*

4.1.2.1 *Bevezetés*

4.1.2.1.1 Amikor az MLS oldalszög antennáját együtt telepítik egy ILS siklópálya adóval, akkor egy döntés sorozatot kell hozni ahhoz, hogy az oldalszög adó antennájának elhelyezését meghatározzák. A telepítési feltételek úgy kerültek kidolgozásra, hogy azok az MLS oldalszög adó berendezésnek az ILS siklópálya adó jeleire - és fordítva -való hatások minimálisra csökkentésén alapulnak. A feltételek a térbeli jellel, az üzemeltetésnél a kritikus területekkel és az akadálymentességi megfontolásokkal együtt befolyással lesznek az oldalszög adó antenna végső elhelyezésére. Mivel egy "púpos" futópálya, vagy a megközelítési fénytechnikai rendszer miatt szükséges lehet az oldalszög adó antenna fázis középpontja magasságának megemelése, ezért ezeket a tényezőket figyelembe kell venni akkor, amikor a következő követelmények bármelyikét alkalmazzák.

4.1.2.1.2 A cél az, hogy az oldalszög adó antenna telepítésének egy megközelítő területével kezdjenek, és azután csökkentsék le azt a területet az adott berendezés optimális elhelyezésére. Ezt a célt úgy lehet elérni, hogy végiglépkednek egy megfontolási sorozat jegyzéken, ami egy logikai folyamatábraként a G-20. számú ábrán kerül bemutatásra.

4.1.2.1.3 A G-20. ábrára hivatkozva a szakasz számok a négy telepítési geometria egyikének felelnek meg, (például az alábbi 4.1.2.2 "az iránysáv adó antenna előtt elhelyezett oldalszög adó antenna", stb.) Minden egyes blokk előtt a számok arra a meghatározott paragrafusra utalnak, amelyek a G-20. ábra alátámasztó szövegei. Ez a paragrafus adja meg azoknak a tényezőknek a részletesebb leírását, amelyeket annál a lépésnél meg kell fontolni.

4.1.2.1.4 Az oldalszög adó antenna telepítésének általános területét a G-21. számú ábra mutatja be.

4.1.2.2 *Az iránysáv adó antenna előtt elhelyezett oldalszög adó antenna*

4.1.2.2.1 Az oldalszög adó antennát az iránysáv irányvonalára szimmetrikusan legalább 30 méterrel (100 láb) az iránysáv adó antenna antenna-sora előtt kell elhelyezni. A maximális távolság értéket (a változtatható "X" a G-21. ábrán) az a követelmény határozza meg, hogy az Annex 14-nek a követelményeit mind az oldalszög adó antenna szerkezetére, mind az oldalszög felügyelő egységre vonatkozóan kielégítsék. Ez az oldalszög antenna előnyben részesített telepítési helye. Azonban, például olyan tényezők miatt, mint az iránysáv közeltéri felügyelő egységének helyzete, szükség lehet az oldalszög adó antenna elhelyezésének módosítására. Az oldalszög adó antennát nem lehet úgy elhelyezni, hogy az lezárja az iránysáv adó antenna és az iránysáv földi felügyelő egysége közötti rálátási vonalat. Amiatt, hogy az oldalszög adó berendezés lezárja az ILS földi ellenőrző pont rálátási vonalat, lehetséges lesz az, hogy az ILS földi ellenőrző pontokat új helyre kell kijelölni.

4.1.2.2.2 Az a kívánatos, hogy a DME / P antennáját együtt telepítsék az oldalszög adó antennával, amikor az csak lehetséges. Azonban, ha a DME / P antennát nem lehet az oldalszög adóval együtt telepíteni az akadálykorlátozási követelmények miatt, akkor egy oldalirányban eltolt DME / P elhelyezést, vagy egy alternatív együtt telepítési elrendezést lehet figyelembe venni (lásd a "C"- Melléklet 7.1.6 pontját és az alábbi 5. szakaszt).

4.1.2.2.3 Amikor lehetséges, az oldalszög adó antenna elhelyezését úgy kell szabályozni, hogy a minimálisra csökkenjen az oldalszög adó antenna kritikus területének a repülési üzemeltetésekre való hatása. Azonkívül, kívánatos lehet az, hogy a maximálisra növeljék az oldalszög adó és az iránysáv adó kritikus területeinek egybeesését. Ha szükségszerű az, hogy az oldalszög adó antennát az iránysáv adó antenna közvetlen szomszédságába telepítsék, akkor szabályszerűen az antennáknak csak az egyikét telepítsék a másik antenna kritikus területén belülre. Az oldalszög adó antenna kritikus területet lásd az alábbi 4.3 pontban. Az iránysáv adó kritikus területet lásd a "C"- Melléklet 2.1.10 szakaszban.

4.1.2.2.4 Miután az oldalszög adó antenna megfelelő helyét meghatározták, meg kell találni az oldalszög antenna földi felügyelő egységének helyét. Az oldalszög adó antennát úgy kell megfigyelni, ahogy az a korábbiakban, a 2.3.5 pontban meghatározásra került. A földi felügyelő rendszer előnyben részesített helye a futópálya meghosszabbított középvonala. Azonban a felügyelő egység oszlopa az oldalszög jelek károsodásának forrása lehet. Ennek megfelelően, ha ez a felügyelő rendszer elhelyezés elfogadhatatlan jel-csökkenést hoz létre, vagy nem kielégítő megfigyelési képességet okoznak a lámpasorok szerkezeti rendszerei, az ILS iránysáv adó stb., akkor egy másik földi felügyelő egység hely lehet kívánatos. Ezt a második megoldást csak akkor ajánljuk, amikor a megközelítési radiál teljes felügyelete rendelkezésre áll. A következő megfontolandó tényezők nyújthatnak segítséget a felügyelő egység elhelyezésének meghatározásához:

a) Az a kívánatos, hogy a földi felügyelő egység olyan közel legyen a távoltérhez, amennyire az gyakorlatilag csak megvalósítható azért, hogy a minimálisra csökkenjen a közeltéri hatás a felügyelő rendszerben. Azonban ezt a távolságot korlátozni kell azért, hogy a felügyelő egység és az oldalszög antenna közötti jármű és légijármű forgalom miatti téves riasztásokat elkerüljék.

b) Az a kívánatos, hogy a minimálisra csökkentsék az oldalszög jeleknek a felügyelő egység általi - a végső megközelítési területre ható - blokkolását és torzítását. A földi felügyelő egységet olyan távol kell elhelyezni az oldalszög adó antenna fázis középpontja alá, amennyire gyakorlatilag csak lehetséges.

c) A földi felügyelő egységnek az antenna középvonalától oldalirányban való elhelyezését korlátozni kell a megfelelő megfigyelési érzékenység fenntartása és a mechanikai stabilitás megtartása érdekében.

d) Az oldalszög adó antenna földi felügyelő egységét úgy kell elhelyezni, hogy elkerüljék azt, hogy hatással legyen az ILS iránysáv adó figyelő egységére, vagy behatást kapjon attól.

4.1.2.3 *Az ILS iránysáv adó mögött elhelyezett oldalszög adó antenna*

4.1.2.3.1 Az iránysáv adó antenna és az MLS oldalszög adó antenna közötti távolság az akadálykorlátozási követelményektől, a rendelkezésre álló tényleges területtől, az iránysáv adó hátsó irányszektor adásától és a DME / P antennának az oldalszög adó antennával való együttes telepítésének kívánatosságától függ. Ha az iránysáv hátsó irányszektor adását használják, akkor egy legalább 30 méteres (100 láb) távolságot kell az oldalszög és az iránysáv adó antennák között biztosítani, és az oldalszög adó antennát az iránysáv adó iránysáv középvonalára szimmetrikusan kell telepíteni. Az olyan iránysáv adó antennák esetében, amelyeknek nagy az előre-hátra teljesítmény-aránya, lehetséges lesz a 30 méteres (100 láb) elkülönítés csökkentése.
Miután az oldalszög és az iránysáv adó antennák közötti távolság ismertté válik, a G-22. számú ábrát lehet felhasználni az oldalszög adó antenna fázis középpontja magasságának az iránysáv adó antenna-sorhoz viszonyított magasságának meghatározására.
Annak biztosítására, hogy az ILS iránysáv adó által okozott jel-szóródás miatti oldalszög útirány-vezetési hiba jelentéktelen (0,03 fok) maradjon, az oldalszög fedésterület teljes területén a "W" pontot

(G-22. ábra) kell jellemzően megválasztani ahhoz, hogy a G-22. ábra változó "X" értékét meghatározzák. Ha ennek a pontnak a kiválasztása egy olyan oldalszög adó antenna elhelyezést eredményez, ami megsérti az akadálymentességi követelményeket, vagy egy olyan torony-építésű telepítést kíván, ami nem megvalósítható, akkor a következő tevékenységeket lehet figyelembe venni:

a) ismerve az érintett meghatározott iránysáv adó és oldalszög adó berendezéseket, elemzést lehet elvégezni az oldalszög adó antenna fázis középpontjának meghatározásához.
Általában az az ajánlott, hogy az oldalszög adó antenna fázis középpontjának magasságát úgy válasszák meg, hogy az iránysáv adó által okozott jel-szóródás miatti útirány-vezetési hiba 0,03 fokra legyen korlátozva. Azonban ezt a kijelölést meg lehet növelni azután, hogy figyelembe veszik az egyéb hibaforrások hozzájárulását is, az olyanokat, mint a földi és légijármű fedélzeti hibák, az épületektől eredő oldalszirom visszaverődések, a földfelszíni visszaverődések és a "zavaró" légijárművek miatti hibák (lásd a G-10. táblázatot); és

b) a W - W_N vonalon (G-22. számú ábra) ki lehet választani egy pontot a változó "X" értékének meghatározásához. Az az előnyösebb, ha a pontot úgy választják meg, hogy olyan közel legyen a "W" ponthoz, amennyire csak lehetséges, és annak az érintett eljárásokhoz üzemeltetésileg elfogadottnak kell lenni. Mivel ennek a követelménynek a kifejlesztéséhez felhasznált hiba elosztás a teljes terjedési hiba halmaznak csak egy kis részét képezi, az oldalszög jel kielégítheti a pontossági követelményeket még azon sík alatt is, ami magába foglalja az oldalszög adó antenna fázis középpontjára kiválasztott pontot. Azt a pontot, amelyre az elfogadható oldalszög jel fennáll, a minimális siklópálya szögön repülési mérésekkel lehet meghatározni.

4.1.2.3.2 Ha az iránysáv adó közeltéri figyelő egysége a futópálya meghosszabbított középvonalában van, akkor az oldalszög adó antenna fázis középpontja magasságának (PCH), vagy az iránysáv adó felügyelő egysége magasságának szabályozására lehet szükség, azért, hogy a minimálisra csökkentsék az iránysáv adó felügyelő egysége oszlopának az oldalszög jelekre gyakorolt hatását. Azonban az előre látható, hogy akkor, amikor a felügyelő egység oszlopának magassága azonos, vagy alacsonyabb az iránysáv adó antenna elemeinek magasságánál, a felügyelő egység oszlopának jelenléte miatti további szabályozásra nem lesz szükség.

4.1.2.4 *Egybeépített oldalszög és iránysáv adó kialakítás*

4.1.2.4.1 *Oldalszög adó antenna az iránysáv antenna-sor alá beépítve*

4.1.2.4.1.1 Ennél a kialakításnál az első figyelembe veendő tényező az akadálymentességi felületnek az iránysáv adó antenna-sora feletti magasságának meghatározása. A földfelszín és az akadálymentességi felület ezen pontja közötti függőleges távolságnak legalább egyenlőnek kell lenni az oldalszög adó antenna magasságával, beleértve a talapzatot és plusz azt a szükséges függőleges 'távolságot', ami az oldalszög adó antenna teteje és az iránysáv adó antenna elemek teteje között szükséges. Ha ezt a feltételt nem lehet betartani, akkor egy másik egybeépített kialakítást kell figyelembe venni.
4.1.2.4.1.2 A 24-elemes log-periódikus iránysáv adónál szerzett kísérleti eredmények azt jelzik, hogy az oldalszög adó antenna teteje és az iránysáv adó antenna elemek alja közötti függőleges térköznek legalább 0,5 méternek (1,6 láb) kell lenni, és egy, a 0,7 méternél (2,3 láb) nagyobb térköz az előnyösebb. Az olyan iránysáv adóknál, amelyeknél az elemeknek viszonylag magasabb a csatolása, a megnövelt függőleges térközt előnyösebbnek tartják.

4.1.2.4.2 *Oldalszög adó antenna az iránysáv adó antenna-soron belülre egybeépítve*

4.1.2.4.2.1 Ennél a kialakításnál nem lehet szükség az akadálymentességi felület magasságának figyelembe vételére, mivel az oldalszög antenna általában alacsonyabb a jelenlegi iránysáv adó antennáknál. Amikor az oldalszög antennát beépítik, akkor az iránysáv antennák bizonyos módosítására van szükség, amelyek befolyással lehetnek az iránysáv térbeli jelére. Azonban a hatások nagymértékben az iránysáv adó típusától függőek.

4.1.2.4.2.2 A két-frekvenciás dipol-antennás iránysáv adóknál szerzett kísérleti eredmények azt jelzik, hogy lehetséges ezeknek a hatásoknak a kiegyenlítése az iránysáv adó antennák kisebb helyszíni módosításaival. Ennek az egybeépített kialakításnak az alkalmazhatóságát az egyes iránysáv adó típusoknál kell megerősíteni.

4.1.2.4.3 Ha egy ILS közeltéri felügyelő egység van elhelyezve, akkor szükséges annak meghatározása, hogy növeljék az oldalszög antenna fázis középpontjának magasságát, vagy csökkentsék az iránysáv adó felügyelő egységének magasságát, ami azért szükséges, hogy a minimálisra csökkentsék a felügyelő egység oszlopának az oldalszög jelekre gyakorolt hatását. Általában kielégítő eredményeket lehet elérni úgy, hogy az oldalszög antenna fázis középpontját körülbelül 0,3 méterrel (1 láb) a figyelő egység oszlopa fölé helyezik el. Ez az érték az iránysáv adó felügyelő egységének felépítésétől és elhelyezésétől függ.

4.1.2.5 *Oldalirányban eltolt helyzetű oldalszög antenna*

4.1.2.5.1 Bizonyos helyeken, ahol az ILS-t és az MLS-t egybeépítve akarják telepíteni, lehetséges, hogy az lehetetlen lesz az MLS antennának az ILS iránysáv antenna alatti, vagy mögötti elhelyezését, vagy az ILS iránysáv antennába való beépítését érintő korlátozások miatt. Ezeken a helyeken kedvező megoldás lehet az, hogy az MLS és a DME / P antennát egy oldalirányú eltolt helyzetben telepítik. A kiegészítő adatokba beadott telepítési információk lehetővé fogják tenni a légijármű fedélzeten az MLS megközelítési középvonal kiszámítását.

4.1.2.5.2 Az ilyen telepítési elrendezésnél az oldalszög adó antennaháznak az előnyös elhelyezése az iránysáv-adó antenna síkjában van (az 1. Terület a G-21. számú ábrán). Az oldalszög adó berendezés és az iránysáv-adó antennasora (utolsó antenna-elem) között a 3 méteres minimális távolságot tartjuk kedvezőnek.

4.1.2.5.3 Ha az oldalszög adó antenna ilyen, az iránysáv-adóhoz viszonyított oldalirányú eltolt helyzetű telepítése gyakorlatilag nem megoldható, akkor az oldalszög adó antennát az iránysáv-adó antennasor síkja mögött lehet telepíteni (a 2. Terület a G-21. sz. ábrán). Az oldalszög adó antenna oldalirányú eltolt telepítésénél legalább 3 m (10 láb) távolságot kell biztosítani, és az oldalszög adó arányos oldalszög útirány-vezetési területére az iránysáv-adó antennasor nem nyúlhat be.

4.1.2.5.4 Ha az oldalszög adó antennát az iránysáv-adó antennasor síkja előtt kell elhelyezni, akkor az az iránysáv jelek teljesítmény-csökkenését eredményezheti. Az a terület, ahol az oldalszög adó berendezésnek az iránysáv-adó jeleire való legkisebb hatása várható, a 3. Terület a G-21. ábrán. Az oldalszög adó antenna elhelyezését egy oldalszög adó berendezés modell felhasználásával lehet vizsgálni.

4.2 Az MLS-nek a megközelítési fénytechnikai rendszeren belüli telepítése

4.2.1 Az ellentétes futópálya irányú megközelítéseket kiszolgáló megközelítési fénytechnikai rendszer befolyásolja az MLS oldalszög adó antenna elhelyezését. A célravezető telepítéshez figyelembe veendő tényezők a fedésterületi követelmények (lásd a korábbi 2.3.2 pontot), annak szükségessége, hogy elkerüljék a fények láthatóságának lezárását, az akadálykorlátozási követelmények és a lámpaszerkezetektől bekövetkező oldalszög jel többutas terjedés elkerülése.

4.2.2 Ezek a követelmények azokra a jellemző telepítésekre alkalmazhatók, ahol a megközelítési fények lényegében egyenlő magasságban kerültek felépítésre, vagy ahol a futópálya végétől mért növekvő távolság függvényében emelkednek.

4.2.3 A következő útmutatások az MLS-nek a jelenleg használatos fénytechnikai rendszer tartószerkezetek közötti telepítésén alapulnak. Jóval célszerűbb lenne olyan lámpaszerkezetek felhasználása, amelyek nincsenek hatással a térbeli jelre, ha ilyenek rendelkezésre állnak.

4.2.4 Ha az MLS oldalszög adó antennának a futópálya meghosszabbított középvonalán 60 méterrel (200 láb) a megközelítési fénytechnikai rendszer távolabbi végén túli telepítése nem lehetséges, vagy gyakorlatilag nem megvalósítható, akkor az antennát el lehet helyezni a fénytechnikai rendszer síkjának határvonalain belül, a következőkben megadott követelmények szerint:

a) a vízszintes síkban, az antennát a futópálya meghosszabbított középvonalában kell elhelyezni, a futópálya megállási végétől 300 méternél nem közelebbi távolságban és a legközelebbi lámpa helyzetétől - a futópálya megállási vége felé - amilyen távolra csak lehetséges. (Ez az oldalszög adó berendezés hátsó részét egy lámpa helyzettel szemben helyezi el.)

b) az oldalszög adó berendezés elhelyezésének olyannak kell lenni, hogy a megközelítési fénytechnikai rendszer fényeinek árnyékolását a minimálisra kell csökkenteni, különösképpen az elhatározási magasság határvonalain belül. Az oldalszög adó berendezés nem takarhat ki semmilyen más lámpá(ka)t, csak olyat, amelyik egy keresztfénysor, vagy egy középvonal fény rövid keresztfénysorának a középső részén helyezkedik el (lásd az Annex 14 I. Kötet "A"- Melléklete 11.3 részében a további útmutatásokat).

4.2.4.1 Ha a szomszédos lámpasorok közötti térköz 30 méter (100 láb), vagy több, akkor az antenna fázis középpontjának legalább 0,3 méterrel (1 láb) a futópálya megállási vége felé lévő legközelebbi lámpasor fény-középpontja felett kell lenni. Ezt le lehet csökkenteni 0,15 méterre (0,5 láb), ha szükséges, és a telepítési helyszín máskülönben mentes a jelentős többutas terjedési problémától. Az szükségessé teheti egy magasabb szintű oldalszög adó berendezés alkalmazását.
4.2.4.2 Ha a szomszédos lámpasorok közötti térköz 30 méternél (100 láb) kevesebb, akkor az antenna fázis középpontnak legalább 0,6 méterrel (2 láb) a futópálya megállási vége felé lévő legközelebbi lámpasor fény-középpontja felett kell lenni.

4.3 A kritikus és érzékenységi területek

4.3.1 Az MLS jelei interferenciájának előfordulása az MLS antennák és az antenna sugárnyaláb szélességek körüli reflektáló és árnyékoló környezet függvénye. A vevő helyétől 1,7 sugárnyaláb szélességen belüli járműveket, vagy állandó akadályokat "sugárnyalábon belülinek" tekintjük, és ezek a fő sugárnyaláb többutas terjedési interferenciáját fogják létrehozni az MLS útirány-vezetési jeleiben. Jellemzően a földi berendezés sugárnyaláb szélességei úgy kerültek meghatározásra, hogy nem áll fenn oldalszög sugárnyalábon belüli reflexió a végső megközelítési útirány mentén, és nem áll fenn magassági szög sugárnyalábon belüli többutas terjedés a meghatározott siklópályán. Azonban mozgó akadályok beléphetnek a sugárnyalábon belüli többutas terjedési területekre és létrehozhatnak zavaró tükrözéseket, vagy az útirány-vezető jelek olyan mértékű kitakarását, hogy a jel minőség elfogadhatatlanná válik. Azokat a területeket, amelyeken belül a járművek csökkentett teljesítményt hozhatnak létre, meg kell határozni és azonosítani. A védő zóna követelmény kifejlesztése céljából ezeket a területeket két típusúra lehet felosztani, azaz kritikus területekre és érzékenységi területekre.

a) Az MLS kritikus terület egy pontosan meghatározott méretű terület az oldalszög és a magassági szög adó antennák körül, ahonnan a járművek - a légijárműveket is beleértve - 'ki vannak tiltva' minden MLS üzemeltetés idején. Ez a terület azért védett, mert a járművek és / vagy a légijárművek jelenléte a területen belül az útirány-vezetési jelek elfogadhatatlan zavarását fogja okozni.

b) Az MLS érzékenységi területe egy, a kritikus területen túlra kiterjedő terület, az, ahol az ott parkoló és / vagy ott lévő járművek - a légijárműveket is beleértve - mozgását szabályozzák, hogy megelőzzék az MLS jelek elfogadhatatlan interferenciájának létrejöttét az MLS üzemeltetések idején. Az érzékenységi terület védelmet biztosít a kritikus területeken kívüli, de még a repülőtér határain belüli nagyméretű akadályok által okozott interferenciával szemben.

1. Megjegyzés. - Ahol az útirány-vezetési jel zavarása csak a földfelszín feletti valamilyen magasságban fordulhat elő, ott a "kritikus tér" vagy "érzékenységi tér" szakkifejezést használjuk.

2. Megjegyzés. - A kritikus és érzékenységi területek meghatározásának célja az, hogy megfelelő védelmet nyújtsanak az MLS útirány-vezetési jelei részére. Az a mód, amelynek megfelelően ezt a szakkifejezést alkalmazzák, az Államok között változó lehet. Néhány Államban a "kritikus terület" szakkifejezést használják annak a területnek a leírására is, amelyre itt az érzékenységi terület kifejezés utal.

4.3.2 A kritikus és érzékenységi területeknek azok a jellemző példái, amelyeknek védelmet kell biztosítani, a G-23. és G-24. ábrán kerülnek bemutatásra. A G-23. és G-24. számú ábrákhoz kapcsolódó táblázatos értékeket azokra a megközelítési eljárásokra kell alkalmazni, amelyeknek a magassági szöge három fokos, vagy annál nagyobb értékű.

A jel minőség biztosításához az szükséges, hogy szabályszerűen tiltsák meg a járművek és a guruló, vagy parkoló légijárművek belépését és tartózkodását ezen a területen belül az összes MLS üzemeltetés idején. Minden egyes oldalszög és magassági szög antenna kritikus területet meg kell határozni. Megfelelő jelző eszközök biztosítása válhat szükségessé az olyan gurulóutakon és utakon, amelyek a kritikus területekbe belenyúlnak, a járművek és légijárművek belépésének korlátozása céljából.

4.3.3 Számítógépes modellezési technikát lehet alkalmazni a különféle méretű és elhelyezkedésű, különböző helyzetű építmények, vagy repülőgépek által okozott jel zavarás nagyságának és fennállási idejének kiszámítására. A jellemző paraméterek, amelyek az ilyen modellezés működtetéséhez szükségesek, azok az antenna sugárnyaláb szélesség és a reflektáló, valamint az árnyékoló akadályok mérete, helye és elhelyezkedése. A földön lévő légijárművek által okozott maximális megengedhető többutas jel csökkenés számításba vételével meghatározhatók a megfelelő kritikus és érzékenységi területek. Ez a módszer került alkalmazásra a G-23. és G-24. ábra kidolgozásánál, számítógéppel történt modellezés olyan megerősítése után, amely magába foglalta a kiválasztott pontok számítógépes eredményeinek és a parkoló légijárműveknek az MLS útirány-vezetési jeleire gyakorolt interferenciája tényleges területi és helyszíni adataival való összehasonlítását.

4.3.4 A kritikus területek ellenőrzése és az érzékenységi területeknek a repülőtéren történő kijelölése tulajdonképpen általában kielégítő lesz az MLS jeleinek a nagy állandó földi 'szerkezetek' által okozott többutas terjedési hatások elleni védelmére. Ez különösképpen akkor fontos, amikor egy új épület méreteit tervezik. A repülőtér határain kívül lévő 'szerkezetek' általában nem fognak problémát okozni az MLS jel minőségére addig, ameddig a szerkezetek az akadálykorlátozási követelményeket kielégítik.

4.3.5 A védett zónák határvonala (azaz az összekapcsolt kritikus és érzékenységi területek) úgy került meghatározásra, hogy a határvonalon kívüli légijárművek és járművek által okozott interferencia nem fog létrehozni a terjedési hatásra jellemzően megengedetteket meghaladó hibákat. Azoknak a megengedhető hibáknak a levezetésénél, amelyek a középvonali megközelítési profilokat védik, ahogy azt a G-10. és G-11. számú táblázat bemutatja, a "tiszta" és az "összetett" terjedési környezet megkapásához a következők szerint járjanak el. A megengedett rendszer hibák a megközelítési vonatkozási pontra (ARD) meghatározott rendszer hiba határértékekből és a terjedési anomáliákra rendelkezésre álló rendszer hiba halmaznál létrejövő fennmaradó részből kerülnek (négyzetes középérték (RSS) alapon) kizárásra. A földi reflexió mind a tiszta, mind az összetett helyszíneknél 'beépítésre' került, mivel az összetett környezetekben egy olyan határérték is fenn van tartva, ami befogadja a kiegészítő hibaforrásokat is, az olyanokat, mint például a tartószerkezet rezgése, a hullámelhajlásos jelek például a megközelítési fénytechnikai rendszer (ALS) lámpáiról és tartószerkezeteiről, vagy a jóval erősebb oldalirányú reflexió.
Végül a fennmaradó hiba maradék 70 százaléka került kijelölésre a védett zónák határvonalának meghatározásához. Ennek megfelelően fennmaradó hiba részek állnak rendelkezésre a védett zónák határainál a szélsőséges esetekre történő meghatározásához, a nagyon tiszta terjedési környezetre - a csak földi reflexiók figyelembevételére, és a nagyon összetett környezetre - a terjedési hibák számos jelentős forrására.

4.3.6 Az MLS kritikus területei kisebbek, mint az ILS kritikus területei. Ahol az MLS antennák az ILS antennák közeli szomszédságában kerültek elhelyezésre, ott az ILS kritikus területek a legtöbb esetben védelmet biztosítanak az MLS-re a megegyező megközelítési pályákra.
Megjegyzés. - Az MLS kritikus és érzékenységi területeinek csökkentését olyan mérések, vagy elemzések útján lehet megkapni, amelyek az adott környezetet veszik figyelembe. Az az ajánlott, hogy a minta méréseket legalább 15 méterenként (50 láb) végezzék el.

4.3.7 *Oldalszög.* Az olyan oldalszög adó antennáknál, amelyek egy, a nulla fokos oldalszögön kijelölt megközelítést szolgálnak ki, az oldalszög adó antenna és a futópálya megállási vége közötti területet kell kritikus területként kijelölni. A G-23. számú ábrán lévő érzékenységi terület biztosít további jel védelmet akkor, amikor alacsony látástávolság melletti üzemeltetések vannak folyamatban. Általában véve, az oldalszög antenna érzékenységi területe a futópálya határvonalain belülre fog esni úgy, hogy megfelelő ellenőrzést lehet gyakorolni minden mozgó forgalom felett azért, hogy megakadályozzák az MLS jelek elfogadhatatlan zavarását. A G-12A. táblázatban megadott érzékenységi terület hosszak kifejlesztésénél az volt alapfeltételként elfogadva, hogy a leszállt B-727 (vagy B-747) típusú repülőgép már elhagyta a futópályát, mielőtt a leszálló repülőgép eléri a 90 méteres (300 láb) magasságot (vagy a 180 métert (600 láb) a B-747-nél)). Ez az alapfeltétel a következő figyelembe veendő tényezők eredményeként jött létre:

a) 5,6 km-es (3 tengeri mérföld) elkülönítést a B-747 méretű repülőgép mögött;

b) 3,7 km-es (3 tengeri mérföld) elkülönítést a B-727 méretű repülőgép mögött;

c) a futópálya foglaltsági idő a leszállt repülőgépnél 30 másodperc, és

d) a megközelítést végrehajtó repülőgép sebessége körülbelül 220 km/óra (2 tengeri mérföld/perc).

4.3.7.1 Egy olyan oldalszög adó antennánál, amely egy oldalirányban eltolt helyzetű megközelítést szolgál ki, a kritikus és érzékenységi területek az oldalszög adó antenna elhelyezésétől és a megközelítési útiránynak a nulla fokos oldalszöghöz viszonyított betájolásától függőek. A kritikus terület az oldalszög adó előtti legalább 300 méteres (1 000 láb) távolságig terjed ki. A folyamatban lévő leszállási üzemeltetések ideje alatti árnyékolás elkerülése céljából további védelem került biztosításra egy érzékenységi terület formájában. A G-12B. számú táblázat adja meg az oldalirányban eltolt telepítésű oldalszög adónál alkalmazott érzékenységi terület hosszát. Amikor az eljárás egy olyan oldalszög mentén kerül végrehajtásra, ami nem a nulla fokos oldalszög, akkor a felülnézeti meghatározásnál a sugárnyaláb kiterjedést kell figyelembe venni. A G-25. ábra mutatja be a jellemző példákat.

Megjegyzés. - Ezt az útmutató anyagot kell a hátsó irányszektor funkciót biztosító oldalszög adó antennára is alkalmazni.

4.3.7.2 *A számított középvonalas megközelítés kritikus és érzékenységi területe.*
A G-26.számú ábra adja meg azoknak a területeknek az általános illusztrációját, amelyeket a nem ellenőrzött földi forgalmi mozgásoktól védeni kell. Ennek a területnek a pontos alakja az oldalszög antenna elhelyezésétől, az oldalszög antenna - futópálya küszöb távolságtól, az elhatározási magasságtól, a berendezésnél üzemeltetett légijárművek típusától és a többutas terjedési környezettől függ.

4.3.7.2.1 A védendő terület meghatározásánál a következő lépések alkalmasak:

a) határozza meg az AG vonal (G-26. ábra) irányát az oldalszög adó antennától (A-pont) a futópálya középvonalának azon legközelebbi pontjáig, ahol az útirány-vezetés szükséges (G-pont);

b) jelölje be a C-pontot az AG- egyenesen az oldalszög antennától akkora távolságra, amit a G-12C, vagy G-12D táblázatban talál az oldalszög antenna - futópálya küszöb távolságra, a földön üzemelő legnagyobb repülőgép méretére és a G-pontnak a minimális siklópályán megadott magasságát;

c) az AB-egyenesnek azonos a hossza az AC-egyenesével és az AC-, valamint az AB-egyenesek egy, a sugárnyalábon belüli többutas terjedés (1,7 sugárnyaláb szélesség) értékkel és egy, a repülési pálya eltérésre figyelembe vett értékkel - ami a megközelítést végrehajtó légijárműnek a névleges megközelítési útiránytól való eltérését veszi számításba - egyenlő értékű szöggel széttartóak;

d) határozza meg az AF-egyenes irányát az oldalszög antennától az F-pontig, ami a minimális siklópályán lévő 300 méteres (1 000 láb) magasságban van;

e) határozza meg az AD-egyenes irányát, aminek a szögbeli széttartása 1,7 sugárnyaláb szélesség az AF-egyenestől;

f) határozza meg az AD-egyenes hosszát a G-12C, vagy G-12D. táblázatból, vegye az F-pont magasságára vonatkozó információval együtt; és

g) a védendő terület az ABCD pontokkal határolt sokszög.

4.3.7.2.2 Jellemzően a G-26. ábra ABCD sokszögének az oldalszög adó antennától legalább az első 300 méteren (1 000 láb), vagy 600 méteren (2 000 láb) belüli részét kell kijelölni külön-külön kritikus területként ott, ahol B-727, vagy B-747 méretű repülőgépek üzemelnek. A terület fennmaradó részét érzékenységi területként jelölik ki. Ahol lehetséges, ott az oldalszög adó antennáját a futópálya azon oldalán lévő eltolt helyzetben jelöljék ki, amelyik a működő futópályákkal ellentétes oldal. Az olyan berendezéseknél, ahol az oldalszög adó antenna hátrafelé elhelyezése 300 méternél kevesebb, vagy ahol a futópálya megállási vége előtt helyezik el, ott egy részletes elemzéssel és a repülőtér elrendezésének figyelembevételével a védendő terület csökkentését alá lehet támasztani.

4.3.7.3 *Az MLS / RNAV eljárások kritikus és érzékenységi területei.* Az MLS / RNAV megközelítési eljárások kritikus és érzékenységi területeit ki kell bővíteni azért, hogy védelmet nyújtsanak a felhasználási szektoron belül a sugárnyalábon belüli többutas terjedéssel szemben. Ezek a kibővített területek olyan megközelítési eljárásokat védenek, amely eljárások az ILS-el nem lehetségesek. A védendő terület hossza a G-13. táblázatból kiválasztott üzemeltetési minimális magasságú felülettől függ. A védendő terület meghatározására vonatkozó tájékoztatásokat a G-27. számú ábra adja meg. A széles körű vizsgálatok során elvégzett szimuláció azt mutatta, hogy ott, ahol B-727 méretű repülőgépek üzemelnek, kielégítő védelmet lehet nyújtani akkor, ha a védett terület első 300 méterét (1 000 láb) jelölik ki kritikus területként, és a fennmaradó részt érzékenységi területként.

A B-747 méretű repülőgépre a megfelelő hossz a 600 méter (2 000 láb). A magasabb megközelítési hossz-szelvényekre a G-13. táblázatból bevezetett hosszak, vagy az itt leírtakkal megegyező értékek kisebbek lehetnek ezeknél az értékeknél; ebben az esetben a teljes kiterjesztett területet kritikus területként lehet kijelölni. Megnövelt rugalmasságot lehet elérni úgy, ha egy, a meghatározott megközelítési szelvényt és a repülőtér környezetét figyelembe vevő elemzést végeznek el.

4.3.8 *Magassági szög.* A védendő magassági szög terület a G-24. számú ábrán bemutatott kritikus térből ered. Általában nincs érzékenységi terület a magassági szög antennára meghatározva. Mivel a kritikus tér alacsonyabb felülete általában jóval a földfelszín felett van, egy légijármű addig várakozhat a magassági szög adó antenna közelében, amíg a kritikus tér alsó határvonalát nem sérti meg.

4.3.8.1 Egy 1,0 fokos sugárnyaláb szélességű, szabályszerű telepítésű magassági szög adó antenna és sík földfelszín esetében a legtöbb repülőgép típus törzse "be fog illeni" a hossz-szelvény, a G-24. ábra kritikus terének alacsonyabb felülete alá.

4.3.8.2 Az 1,5 fokos sugárnyaláb szélességű magassági szög adó antennának a G-24. ábra kritikus tér hossz-szelvénye alsó felületének az egy légijármű törzse általi korlátozott benyúlást úgy lehet "eltűrni", hogy a kritikus tér alsó részét az 1,5 fokos és az 1,7 sugárnyaláb szélességű, a minimális siklópálya alatti részt érzékenységi térként határozzák meg. Az olyan helyszíneken, amelyek jól teljesítik a tűréshatárokon belüli értéket, a repülőgépek várakozhatnak az antenna előtt, feltéve, hogy:
a) a siklópálya és a repülőgép törzsének teteje közötti szögelkülönítés legalább 1,5 fok;
b) a repülőgép függőleges vezérsíkja nem sérti meg a kritikus tér alsó felületet; és
c) a törzs derékszögben áll a középvonalra.

4.3.8.3 Az MLS / RNAV megközelítési eljárásoknál a magassági szög kritikus területének felülnézete részét ki kell bővíteni azért, hogy biztosítsa a magassági szög jel minőséget. Ezek a kibővített területek védik azokat a megközelítési eljárásokat, amelyek az ILS-el nem lehetségesek.
Az oldalnézet jellemzői (G-24. ábra) változatlanok maradnak, semmi más nem változik, csak az alacsonyabb határvonal a névleges megközelítési útirányra van vonatkoztatva. Ez az útmutató anyag az oldalnézetek széles sorozatát fedi. Megnövelt rugalmasságot lehet elérni úgy, hogyha elvégzik a meghatározott megközelítési oldalnézetnek az adott repülőtér környezetében való elemzését.

5. A DME földi berendezés telepítésére vonatkozó üzemeltetési megfontolások

5.1 A DME berendezésnek, amikor csak lehetséges, nulla távolság jelzést kell adni a légijármű vezetője részére a földetérési pontnál, abból a célból, hogy a jelenleg érvényes üzemeltetési követelményeket kielégítsük.

5.1.1 Amikor egy DME / P berendezést telepítenek az MLS-el, akkor az MLS adatokból származó koordináta információkat felhasználó fedélzeti berendezés az MLS vonatkozási ponthoz viszonyított nulla távolság jelzést kaphatja meg. A DME nulla távolságot a DME / P helyéhez kell viszonyítani.

6. A földi berendezés felügyelő rendszere és vezérlési tevékenysége között kölcsönös kapcsolat

6.1 A felügyelő és vezérlési tevékenység közötti kölcsönös kapcsolatot annak biztosításához tartják szükségesnek, hogy a légijármű ne vehessen egy olyan hiányos útirány-vezetést, amely veszélyeztetheti a biztonságot, hanem minden időben folyamatosan olyan érvényes útirány-vezetést vegyen, amelyet biztonságosan felhasználhat még abban az esetben is, ha bizonyos funkciók sugárzása megszűnik.

Megjegyzés. - A földi berendezés felügyelő és vezérlési tevékenysége közötti kölcsönös kapcsolatot a G-14. táblázat mutatja be.

7. Fedélzeti berendezés

7.1 Általános rész

7.1.1 Az ezen részben található fedélzeti berendezés paraméterek és tűrések arra a célra szolgálnak, hogy a 3. Fejezet 3.11 pontjában lévő Szabványok értelmezését lehetővé tegyék, és ahol lehetséges, magukba foglalják a megengedett eltéréseket a következőkre vonatkozóan:

a) a földi berendezés paramétereinek változására a 3. Fejezet 3.11 pontjában meghatározott határértékeken belül;

b) azokra a légijármű sebességekre, manőverekre és magasságokra, amelyek rendes körülmények között egy adott fedésterületen belül előfordulnak.

1. Megjegyzés. - A fedélzeti berendezés magába foglalja a légijármű antennáit, a fedélzeti vevőt, a pilóta interface berendezését és a szükséges belső kapcsolatokat.

2. Megjegyzés. - Az MLS repülési elektronika részletes "Minimális Teljesítmény Előírások" című anyagot az EUROCAE és az RTCA állította össze és koordinálta. Az ICAO időről időre elküldi a Szerződőd Államoknak ezen szervezetek minden olyan kiadványának jegyzékét, amelyeket nemzetközi szinten egyeztettek a Hetedik Léginavigációs Konferencia 3/18(a) és 6/7(a) számú Ajánlásainak megfelelően.

7.1.2 *Funkció dekódolás*

7.1.2.1 A fedélzeti berendezésnek képesnek kell lenni a megközelítési oldalszög, a nagysebességű megközelítési oldalszög, a hátsó irányszektor oldalszög és a megközelítési magassági szög funkciók, valamint a tervezett üzemeltetéshez szükséges adatok dekódolására és feldolgozására.

7.1.2.2 Azonkívül a vevőnek olyan technikát kell felhasználni, amely megakadályozza az olyan funkciók feldolgozását, amelyek az adatmezőkön belüli, vagy az alap és kiegészítő adatszavakban, valamint a letapogató sugárnyalábok oldalszirom sugárzásaiból eredő beágyazott funkció bevezető jelszakaszok jelenlétéből erednek. Ennek a megvalósítását lehetővé tevő egyik technika az összes bevezető jelszakasz dekódolása. A bevezető jelszakasz dekódolása után az összes funkció bevezető jelszakasz észlelése és dekódolása letiltásra kerül a funkció hosszának megfelelő időtartamra.

7.1.2.3 A távolság tájékoztatást függetlenül kell dekódolni.

7.1.3 A vevőnek dekódolni kell azt a teljes szögtartományt, amelyet az egyes funkciók jel formátuma lehetővé tesz. Az útirány-vezetési szöget a vevő a TO és FRO letapogatások vett burkológörbéi közötti időközök mérésével határozza meg. A dekódolt szög a 3. Fejezet 3.11.4.5 pontjában megadott képlet szerint van erre az időközre vonatkoztatva.

7.1.4 A vevőnek képesnek kell lenni minden egyes sugárzott funkció szabályos feldolgozására, függetlenül attól, hogy a funkció az adás sorrendjében hol helyezkedik el.

7.1.5 Amikor az MLS megközelítési oldalszög és hátsó irányszektor információkat a kiválasztón és / vagy a fedélzeti műszereken megjelenítik, akkor azokat mágneses fokokban kell kijelezni. Az automata radar kijelzős vevők részére a vonatkozó információt a földi állomás a 4. alap adat szó részeként adja le.

7.1.6 A vevőnek képesnek kell lenni a megközelítési útirány, a magassági szög és a hátsó irányszektor radiál - ha ilyent biztosítottak - mind manuális, mind automatikus kiválasztására. Az automatikus módban a kiválasztás a következők szerint történik.

7.1.6.1 *Megközelítési oldalszög* válassza ki a megközelítési oldalszög mágneses betájolása megfordított szögértékét a 4. alap adatszóból.

7.1.6.2 *Magassági szög* válassza ki a minimális siklópályát a 2. alap adatszóból.

7.1.6.3 *Hátsó irányszektor* válassza ki a hátsó irányszektor szögének mágneses betájolását a 4. alap adatszóból.

Megjegyzés. - A vevő jelzi azt, amikor az eltérés a hátsó irányszektor jelre vonatkozik.

7.1.7 Az MLS fedélzeti vevő rendszerének olyan integritás összeegyeztethetőségének kell lenni az MLS teljes integritásával, ami legalább 1 - 1 10^{-7} minden egyes leszállásnál.

7.1.8 Az MLS / RNAV üzemeltetéseknél használt fedélzeti berendezéseknél biztosítani kell azt a képességet, hogy a kiválasztott eljárást egyértelműen kijelezze.

7.2 Rádiófrekvenciás jelleggörbe

7.2.1 *Vételi sávszélesség*

7.2.1.1 A vevőnek ki kell elégíteni a vételi és teljesítmény követelményeket akkor, amikor a vett jel frekvencia eltolódása a szabvány csatorna középfrekvenciától plusz, vagy mínusz 12 kHz-ig terjed. Ez a szám plusz, vagy mínusz 10 kHz-es lehetséges földi adó eltolódást és plusz, vagy mínusz 2 kHz-es Doppler eltolódást vesz figyelembe. A vevőnek dekódolni kell valamennyi funkciót, függetlenül attól, hogy az egyik funkció frekvencia eltolódása eltolódik a másiktól.

7.2.2 *Szelektivitás*

7.2.2.1 Amikor a vevőt egy nem működő csatornára hangolják, és egy, a 3. Fejezet 3.11.4.10.1 pontjában a megközelítési oldalszög differenciális fáziseltolásos kódolású meghatározott érték felett 33 dB-es jelszintű nem-kívánt MLS jelet adnak a fennmaradó csatornák bármelyikére, a vevő nem érzékelheti a jelet.

7.2.3 *Csatornán belüli hamis vétel*

7.2.3.1 A 3. Fejezet 3.11.6 pontjában meghatározott vevő teljesítményt akkor is ki kell elégíteni, amikor a vevő ugyanazon a csatornán a 3. Fejezet 3.11.4.1.4 pontjában meghatározottat meg nem haladó szintű interferenciát vesz.

7.2.4 *Sávon kívüli adásokból eredő interferencia*

7.2.4.1 A 3. Fejezet 3.11.6 pontjában leírt vevő teljesítményt akkor is ki kell elégíteni, amikor egy -124,5 dBW/m^2-t meg nem haladó szintű nem-kívánt vett jelből eredő interferencia van az MLS vevő antennán.

7.3 Jel feldolgozás

7.3.1 *Vétel (jel begyűjtés)*

7.3.1.1 A vevőnek egy, a 3.11.4 pontban leírt követelményeknek megfelelő bemenő útirány-vezetési jel előfordulása esetén be kell fogni és érvényesíteni kell az útirány-vezetési jeleket a követési módra történő átállás előtt 2 másodpercen belül, a megközelítés kritikus része mentén, és 6 másodpercen belül a fedésterület határvonalánál.

7.3.2 *Követés*

7.3.2.1 A követés során a vevőnek védelmet kell biztosítani a rövid időtartamú nagy amplitúdójú hamis jelek ellen. Az útirányra való ráállás után a vevőnek érvényes útirány-vezetési tájékoztatást kell adni a figyelmeztető jelzés eltávolítása előtt. A követési mód során az érvényesítési folyamatnak tovább kell működni.

7.3.2.2 A követési jel egy másodpercnél hosszabb idejű elvesztése után a vevőnek figyelmeztető jelzést kell adni. Az egy-másodperces időtartamon belül az útirány-vezetési információnak az utolsó kimeneti értéken kell maradni.

1. Megjegyzés. - Egy érvényesített útirány-vezetési jel az, amelyik a következő követelményeket kielégíti:

a) helyes funkció azonosítás dekódolt;

b) a bevezető jelszakasz időzítő jel dekódolt;

c) a "TO" és "FRO" letapogató sugárnyalábok vagy a bal / jobb biztonsági vezetési jelek jelen vannak, és a középponti időhöz viszonyítottan szimmetrikusan helyezkednek el; és

d) az észlelt sugárnyaláb szélesség 25-től 250 mikroszekundumig terjed.

2. Megjegyzés. - Az útirány-vezetési jel érvényesítése szükségessé teszi azt is, hogy a vevő ismétlődően megerősítse, miszerint a vett és követett jel a legnagyobb és legfolytonosabb jel a fedésterületen belül.

7.3.3 *Adat funkciók*

7.3.3.1 *Adat felismerés.* A fedélzeti adatfelismerési teljesítmény akár az alap-, akár a kiegészítő adatként biztosított adatfunkciókra két egységre van osztva: az adatgyűjtésre megengedett időre és a megszerzett adatokban előforduló felderítetlen hiba valószínűségére.

7.3.3.1.1 A minimális jel teljesítmény-sűrűségnél az alap adatszó 2. felismerésének ideje - amely a 6,25 Hz-es átviteli sebességgel kerül leadásra - nem haladhatja meg a két másodpercet egy 95 százalékos valószínűségi alapon. Az 1 Hz-es átviteli sebességgel leadott adatok felismerésének ideje nem haladhatja meg a 6 másodpercet a 95 százalékos valószínűségi alapon.

7.3.3.1.2 Az adatfelismerési folyamatban a vevőnek dekódolnia kell a megfelelő adatszavakat és meghatározott ellenőrzéseket kell végrehajtania azokon, annak biztosítására, hogy a felderítetlen hibák valószínűsége ne haladja meg az 1×10^{-6} értéket a minimális jel teljesítmény-sűrűség mellett azokra az adatokra, amelyek az integritás ilyen szintjét igénylik. A felderítetlen hibákra ajánlott teljesítmény előírások szükségessé tehetik az egyszerű dekódoláson túl az adatoknak a fedélzeten történő további feldolgozását. Például ezeket az ugyanazon adatszavak többszörös minta szerinti feldolgozásánál lehet elérni.

7.3.3.1.3 Ha a vevő nem tudja 'begyűjteni' a tervezett üzemeltetéshez szükséges adatokat, akkor egy megfelelő figyelmeztetést kell biztosítania.

7.3.3.1.4 A minimális jel teljesítmény-sűrűség mellett az MLS / RNAV üzemeltetések alátámasztásához szükséges (kiegészítő adatszavak B1 - B41, A1/B42, A2, A3, A4/B43 és az alap adatszó 6.) összes adatszó 'begyűjtésének' ideje nem haladhatja meg a 20 másodpercet egy 95 százalékos valószínűségi alapon. az MLS / RNAV berendezésnek biztosítania kell azt, hogy a felderítetlen hibák valószínűsége erre az adat-blokkra ne haladja meg a $0{,}5 \times 10^{-9}$-t. Ez a teljesítmény 2 dB-es jel-zaj javulást fogad el alapfeltételként. Ezt csökkentett kábelcsillapításon, teljesítőképesség határon működő, vagy megnövelt vevő érzékenységen keresztül lehet elérni (lásd a fedélzeti teljesítmény halmazt, ami a G-2. táblázatban került megadásra). Azonkívül az ezen felüli jelszintekkel az adatfelismerési időnek a tervezettnek megfelelően 20 másodpercnél kevesebbnek kell lenni.

7.3.3.2 *Adat érvényesítés.* Az adatok felismerése után a vevőnek ismétlődően meg kell erősítenie azt, hogy a vett adatok azonosak a felismert adatokkal. A vevő dekódol több olyan egymás után következő és egyforma adatot, amelyek eltérnek azoktól, amit az előzőekben begyűjtött, mielőtt megkezdené az új dekódolt adat elfogadásának tevékenységét.

7.3.3.2.1 Az MLS / RNAV üzemeltetések alátámasztásához szükséges adatokra a fedélzeti berendezés alkalmazza a ciklikus redundancia ellenőrzést (CRC) azért, hogy biztosítsa azt, hogy az adat kielégítő integritása elérésre került. Az adatokat, amiket folyamatosan vesz, folyamatosan érvényesíti is. Az MLS / RNAV berendezések nem fogadnak el egy új adat-blokkot felhasználásra addig, amíg azt a ciklikus redundancia ellenőrzés nem érvényesíti.

7.3.3.3 *Adat elvesztés.* Hat másodpercen belül, hogy az alap, vagy kiegészítő adat elveszett, amit egy 2 másodperces, vagy annál kisebb maximális időközzel adnak le, a vevőnek biztosítani kell egy megfelelő figyelmeztető jelzést, és el kell távolítania a meglévő adatokat. Harminc másodperccel az olyan kiegészítő adatok elvesztése után, amelyek nem tartoznak a korábbiakban említettek közé, a vevőnek biztosítania kell egy megfelelő figyelmeztető jelzést.

7.3.3.3.1 Az MLS / RNAV üzemeltetések alátámasztásához szükséges adatokat a fedélzeti berendezésnek nem kell eltávolítania a meglévő adatokból az érvényesítést követően, kivéve csak a fenti 7.3.3.2.1 pontban leírt feltételek mellett. Egy olyan MLS / RNAV adatblokkot, amelyet a ciklikus redundancia ellenőrzés érvényesített, nem kell eltávolítani addig, amíg egy új adatblokk vételre nem kerül, egy eltérő földi berendezés azonosítóval az alap adatszó 6-ban, egy új MLS csatorna kerül kiválasztásra, vagy az áram kikapcsolásra kerül. Azonkívül, az adatblokk nem kerül eltávolításra akkor, amikor átmenet történik a hátsó irányszektor fedésterületre.

7.3.4 *Többutas terjedési teljesítmény*

7.3.4.1 Ahol a kisugárzott jel teljesítmény-sűrűsége elég nagy ahhoz, hogy a fedélzeti berendezés termikus zaját jelentéktelenné tegye, ott a következő előírásokat kell alkalmazni a 0,05 Hz és a 999 Hz közötti lengési frekvenciákra.

7.3.4.1.1 *A sugárnyalábon belüli többutas hullámterjedés.* Azok a többutas hulámterjedésből származó jelek, amelyeket a közvetlen jeltől két sugárnyaláb szélességnél kisebbre kódoltak, és amelyeknek az amplitúdója 3 dB-el, vagy többel a közvetlen jel alatt van, nem csökkenthetik le a szög útirány-vezetési pontosság kimenetet plusz, vagy mínusz 0,5 sugárnyaláb szélességnél nagyobb értékkel (csúcs-hiba).

7.3.4.1.2 *Sugárnyalábon kívüli többutas hullámterjedés.* Azok a többutas hullámterjedésből származó jelek, amelyeket a közvetlen jeltől két sugárnyaláb szélességnél nagyobbra kódoltak, és amelyeknek az amplitúdója 3 dB-el, vagy többel a közvetlen jel alatt van, nem csökkenthetik le a szög útirány-vezetési pontosságot plusz, vagy mínusz 0,02 sugárnyaláb szélességnél nagyobb értékkel.

7.3.5 *Biztonsági vezetés*

7.3.5.1 A fedélzeti berendezésnek biztonsági vezetési tájékoztatást kell biztosítani akkor, amikor az antenna egy érvényes biztonsági vezetési jel környezetben van.

7.3.5.2 Amikor a dekódolt szög kijelzés a 3. Fejezet A-7. táblázatában meghatározott arányos vezetési szektoron kívül van, akkor az MLS útirány-vezetési jelet biztonsági vezetési jelként kell értelmeznie.

7.3.5.3 Amikor biztonsági vezetési impulzusokat sugároznak, akkor a vevőnek képesnek kell lenni azon impulzus burkológörbe alakok távolságának feldolgozására, amelyek a biztonsági vezetési és letapogató sugárnyaláb jelei közötti átmenetben jelenhetnek meg. Egy egyedi impulzus burkológörbe a vevő helyzetétől, a letapogató antenna sugárnyaláb szélességétől és a biztonsági vezetési és letapogató sugárnyaláb jelek relatív fázisától és amplitúdó arányától függ, ahogy az a G-8. számú ábrán bemutatásra került. A vevőtől megkívánt még az is, hogy feldolgozza az 1,5 fokos nagyságrendig terjedő (csúcs amplitúdó) kijelzett szög gyors változásait, akkor, amikor az arányos útirány-vezetési határokon kívül van.
7.3.5.4 Azoknak a vevőknek, amelyek képesek arra, hogy kiválasszák, vagy kijelezzék a plusz, vagy mínusz 10 foknál nagyobb oldalszög szög útirány-vezetési tájékoztatásokat, az alap adatokban lévő arányos fedésterületi határértékeket dekódolni kell, és fel kell azt használni a hibás útirány-vezetés felhasználásának kizárására.

7.4 Vezetés és kimenet

7.4.1 *Megközelítési oldalszög és megközelítési magassági szög eltérési lépték-tényező*

7.4.1.1 *Megközelítési oldalszög.* Amikor a megközelítési oldalszög eltérési információnak az a célja, hogy ugyanazt az érzékenységi jellemzőt adja meg, mint az ILS, akkor az a "megközelítési oldalszög antenna - futópálya küszöb távolság" egyik funkciója és az alap adatok által továbbítani kell a következő táblázatban leírtaknak megfelelően:

Megközelítési oldalszög antenna - futópálya küszöb távolság (ATT)	Névleges iránysáv szélesség
0 - 400 m	±3,6 fok
500 - 1 900 m	± 3,6 fok
2 000 - 4 100 m	$\pm \arctan\left(\frac{105}{ATT}\right) fok$
4 200 - 6 300 m	1,5 fok

7.4.1.2 *Megközelítési magassági szög.* Az eltérési információ a kézzel, vagy automatikusan kiválasztott magassági szög (Θ) egy folyamatos funkciója a Θ/4 = a névleges siklópálya szélesség fele képletnek megfelelően úgy, hogy a siklópálya szélességek névlegesen a következő példáknak felelnek meg:

A kiválasztott magassági szög (fok)	Névleges siklópálya szélesség (fok)
3	0,75
7,5	1,875

Megjegyzés. - Ezek az érzékenységi jellemzők alkalmazhatók a 7,5 fokig terjedő magassági szögekre.

7.4.2 *A szög adat kimeneti szűrő jellemzői*

7.4.2.1 *Fáziskésés.* A megfelelő robotpilóta csatlakozó egység biztosításához a vevő kimeneti szűrőn a szinuszos bemeneti frekvenciákra nem rendelkezhet olyan fáziskéséssel, ami meghaladja:

a) a 4 fokot a 0,0-tól a 0,5 rad/s-ig az oldalszög funkcióra; és

b) a 6,5 fokot a 0,0-tól az 1,0 rad/s-ig és a 10 fokot az 1,5 rad/s-nál a magassági szög funkcióra.

7.4.3 *A minimális siklópálya.* Ahol fennáll a megközelítési magassági szög kiválasztásának lehetősége, ott egy megfelelő figyelmeztető jelzést kell adni akkor, amikor a kiválasztott szög alacsonyabb annál a minimális siklópályánál, amely az alap adatszó 2-ben megadásra került.

7.4.4 *Állapotjelző bitek.* Egy megfelelő figyelmeztetést kell biztosítani akkor, amikor a felismert alap adatokban a funkció állapotjelző bit azt jelzi, hogy a megfelelő funkció nem kerül sugárzásra, vagy ellenőrző üzemmódban kerül sugárzásra.

7.5 A hátsó irányszektor útirány-vezetés felhasználása a megszakított megközelítésekre és az indulásokra

7.5.1 *A felhasználható hátsó irányszektor szögek*

7.5.1.1 Repülési ellenőrzések eredményei azt jelezték, hogy a hátsó irányszektor szögei a futópálya középvonalától a 30 fokig felhasználhatók a megszakított megközelítések és az indulások navigációs útirány-vezetésére. Megfelelő befogási technikával nagyobb eltolt szögek is elfogadhatók lehetnek, egészen a hátsó irányszektor fedésterületének repülhető határértékéig. Az indulási útirány-vezetéshez fel lehet használni a hátsó irányszektor jelet középvonal útirány-vezetésként a felszállási nekifutás és a kezdeti indulás teljes területén. Az a cél, hogy egy, a hátsó irányszektor befogásához végrehajtott forduló egy üzemeltetésileg elfogadható magasságon kezdődjön meg, és az előírt eljárás a vonatkozó akadálymentességi követelményeknek megfelelően védett legyen.

7.5.2 *A hátsó irányszektor eltérési léptéke*

7.5.2.1 A leolvasási hátsó irányszektor eltérésnek kielégítőnek kell lenni ahhoz, hogy alátámassza azokat a hátsó irányszektor indulásokat és megszakított megközelítéseket, amelyek nem a megközelítési iránnyal egybeesően kijelöltek, valamint azokat a megszakított megközelítéseket és indulási útirányokat, amelyek a megközelítési iránnyal egybeesően kerültek kijelölésre. A leolvasási eltérési hatás akkor a legkifejezettebb, amikor egy, a hátsó irányszektor szög befogására való manőverezés történik. A nagyon érzékeny leolvasás oldalirányú eltolódású átstartolást fog okozni, és korlátozza a jel repülhetőségét, ellenben a nagyon intenzív leolvasás a légtér nagymértékű felhasználását fogja eredményezni. A 6 fokos névleges iránysáv szélességi érzékenység egy elfogadható befogást biztosít a hátsó irányszektorban a megszakított megközelítés és az indulás során.

7.5.3 A megközelítési oldalszögnél a hátsó irányszektorra történő átkapcsolás

7.5.3.1 Egy hátsó irányszektor útirány-vezetést felhasználó megszakított megközelítés megkezdését követően az útirány-vezetést át kell kapcsolni a megközelítési oldalszögről a hátsó irányszektor szögére. Az átkapcsolás akár automatikusan, akár kézzel, a megközelítési oldalszög útirány-vezetésről a hátsó irányszektor útirány-vezetésre azt a célt szolgálja, hogy folyamatos repülhető útirány-vezetés legyen biztosítva a teljes megszakított megközelítési szakaszban. Az átkapcsolás bekövetkezése nem várható addig, amíg a légijármű nem vesz egy érvényesített hátsó irányszektor jelet, de a bekövetkezése várható az előtt, mielőtt a megközelítési oldalszög útirány-vezetés a repüléshez túl érzékennyé válik. A megközelítési oldalszög elvesztésére alapozott átkapcsolás nem következhet be addig, amíg a repülőgép nincs annyira közel a megközelítési oldalszög antennához, hogy az repülhetetlen útirány-vezetést eredményez. A csak egy magassági szögvezetés elvesztésén alapuló átkapcsolás bekövetkezhet azt megelőzően, hogy a légijármű egy érvényes hátsó irányszektor jelet vesz.
Azonban az átkapcsolást lehet a magassági szögvezetés elvesztésére alapozni azután, miután a hátsó irányszektor jel érvényesítésre került. Az automatikus átkapcsolás az oldalszög antennák közötti középső-pontban, vagy annak közelében egy olyan módszert fog biztosítani, ami a folyamatos útirány-vezetést eredményezi az átmenet során. A középső-pont átkapcsolási módszer szükségessé teszi a DME információknak az MLS vevő általi felhasználását. Óvintézkedéseket kell tenni az ellen, hogy a megközelítési hátsó irányszektor oldalszög átkapcsolás ne következzen be automatikusan anélkül, hogy a megszakított megközelítés megkezdődne.

8. A közzétett MLS fedésterületi szektorok határán és az azon kívüli területen történő üzemeltetések

8.1 Az arányos oldalszög útirány-vezetési szektor határértékek az alap adatszó 1- és 5-ben kerültek kisugárzásra. Ezek a határértékek nem az MLS megközelítési és hátsó irányszektora maximális repülhető szögeit jelzik, mivel azok általában néhány fokkal ezen határértékeken belül lesznek. Például a ±40 fokos arányos útirány-vezetési szektort biztosító megközelítési oldalszögeknél a repülhető MLS megközelítési oldalszögek egy ±3 fokos teljes iránysáv szélességgel körülbelül ±37 fokig terjednek ki. A hátsó irányszektorra a repülhető hátsó irányszektor szögek - teljes iránysáv szélességnél - az arányos útirány-vezetési szektor határértékein belül 6 fokkal lesznek.

8.2 Az alap MLS antenna tervezés eleve kizárja a fedésterületeken kívüli nem-kívánt jelek létrehozását. Bizonyos rendkívüli telepítési körülmények esetén, az MLS jelek reflektálódhatnak a közzétett fedésterületen kívüli területekre elégséges erősséggel ahhoz, hogy hibás útirány-vezetési tájékoztatást okozzanak a vevő részére. A jelenleg érvényben lévő eljárások szerint a telepítést végző hatóságnak kell meghatározni az üzemeltetési eljárásokat olyan további navigációs berendezések felhasználásával, amelyek a légijárművet a leszállító rendszer fedésterületén belülre hozzák, anélkül, hogy az érintett /a fenti/ területen áthaladna, vagy közzé tehet olyan tájékoztató anyagokat, amelyek figyelmeztetik a légijárművezetőket a körülményekre. Ezenkívül, az MLS jel formátum lehetővé teszi két olyan technika alkalmazását, ami tovább csökkenti a hibás zászló működés előfordulási valószínűséget.

8.2.1 Ha a nem-kívánt MLS jelek reflexiótól származnak, és az üzemeltetési feltételek lehetővé teszik, akkor a fedésterületi szektort be lehet állítani (növelve, vagy csökkentve) úgy is, hogy a vevőnél vagy a közvetlen jel lesz bármilyen reflexiónál nagyobb, vagy a visszaverő felületre nem jut sugárzás. Ezt a technikai megoldást nevezik fedésterület szabályozásnak.

8.2.2 Fedésterületen-kívül jelzést (OCI) lehet kisugározni a fedésen kívüli szektorba, amelyeket a vevő arra használhat fel, hogy biztosítsa a zászló jelzést bármikor, ha egy nem-kívánt útirány-vezetési jelet észlel. Ezt úgy lehet megválasztani, hogy egy olyan fedésterületen-kívül jelet sugároznak ebbe a körzetbe, amelynek a nem-kívánt útirány-vezetési jelnél nagyobb a jel nagysága.

8.3 Ha üzemeltetési szempontból szükséges az, hogy a kiválasztott MLS csatorna vételét az MLS-re közzétett fedésterületi szektorokon kívül hitelesítsék, akkor az a cél, hogy ez a hitelesítés a kapcsolódó DME azonosításából kerüljön levezetésre. Az MLS állapot információk nem állnak a légijármű rendelkezésére a közzétett MLS fedésterületi szektorokon kívül.

9. Elkülönítési követelmények a jelviszony és a terjedési veszteség mértékében kifejezve

9.1 Földrajzi elkülönítés

9.1.1 Az alábbi 9.2 és 9.3 pontokban leírt elkülönítési követelmények a megkívánt jel / zaj arányaként kerültek megadásra, és amikor ezeket a megfelelő terjedési veszteségekkel összekapcsolják, akkor lehetséges lesz az MLS C-sávú frekvenciák kijelölésének megállapítása az azonos csatornák és a szomszédos csatornák interferenciája szempontjából. Amikor az MLS berendezések frekvenciáit kiválasztják, akkor a berendezés DME / P elemére, vagy egy kapcsolódó DME / N berendezésre az ennek a résznek a "C"- Mellékletében megadott azonos követelményeket kell figyelembe venni.

9.2 Az azonos frekvenciára vonatkozó követelmények

9.2.1 Az azonos frekvenciájú MLS csatorna kiosztást azért kell létrehozni, hogy eleve megakadályozzák a differenciális fáziseltolásos kódolás bevezető jelszakaszainak az egy nem-kívánt azonos frekvenciájú berendezéstől való 'begyűjtését'. A nem-kívánt jel szükséges szintje mínusz 120 dBm-nél kevesebb, ami 2 dB-el van egy érzékeny MLS fedélzeti rendszer szintje alatt, ahogy az alábbiakban látható:

—	vevő érzékenység	=	-112 dBm
—	a légijármű antenna nyereségének a minimum feletti tűrése	=	-6 dBm
			-118 dBm

A G-1. táblázatban lévő rendszer teljesítmény összegzést figyelembe véve, ez azt mutatja, hogy a légijárműnél a minimális jel szintnek legalább mínusz 95 dBm-nek kell lenni, a mínusz 120 dBm követelmény úgy érhető el, ha a nem-kívánt azonos csatornát olyan földrajzi elkülönítéssel helyezik el, ami meghaladja a rádióhorizont távolságot a kívánt berendezésre közzétett fedésterületi szektor minden pontján.

Megjegyzés. - A differenciális fáziseltolásos kódolási jel a letapogató sugárnyalábnál több védelmet kíván, úgy, hogy a nem-kívánt azonos csatornájú jelnek a mínusz 120 dBm-re történő határolása mellett a letapogató sugárnyalábtól eredő interferencia elhanyagolható.

9.3 A szomszédos frekvenciára vonatkozó követelmények

9.3.1 Az első és második szomszédos frekvenciákhoz tartozó adó spektrum jellemzőkre vonatkozó előírások hiányát figyelembe véve, az ezeken a frekvenciákon működő földi állomásokat olyan földrajzi elkülönítéssel kell elhelyezni, ami meghaladja a rádióhorizont távolságot a kívánt berendezésre közzétett fedésterületi szektor minden pontján.

Megjegyzés – Ahol különleges szempontok miatt (például, ILS/MLS/DME csatorna párosítás miatt) az első és a második szomszédos csatornát ki kell osztani, a vevő védelmének egy kevésbé körültekintő eljárása az, amikor garantáljuk, hogy a 3.11.6.1.4 pontban megállapított minimális Jel / Zaj arány

(SNR) értékek rendelkezésre állnak a kívánt berendezés érvénybe léptetett fedésterületi szektorának bármelyik pontján, miközben a nem-kívánt berendezés folyamatosan sugároz.

9.3.2 A harmadik és a további szomszédos csatornáknál, az ezeken a frekvenciákon működő földi állomásokat olyan földrajzi elkülönítéssel kell elhelyezni, ami garantálja, hogy a 3.11.6.1.4 pontban megállapított minimális Jel / Zaj arány (SNR) értékek rendelkezésre állnak a kívánt berendezés érvénybe léptetett fedésterületi szektorának bármelyik pontján, miközben a nem-kívánt berendezés folyamatosan sugároz.

9.3.2.1 Ha az érvénybe léptetett fedésterületi szektorának bármelyik pontjától kevesebb, mint 4 800 m távolságból nincs nem-kívánt MLS sugárzás, a 3. Fejezet 3.11.4.1.4.2 pontban megállapított -94,5 dBW/m^2 maximális teljesítmény, összehasonlítva a 3. Fejezet 3.11.4.10.1 pontban megállapított minimális teljesítmény sűrűséggel, biztosítja, hogy a jel / zaj arány (SNR) értékek elérhetők lesznek. Semmilyen kényszer nem látható előre.

9.3.2.2 Ha az érvénybe léptetett fedésterületi szektorának bármelyik pontjától kevesebb, mint 4 800 m távolságból van nem-tervezett MLS sugárzás, az ilyen sugárzással létrejövő maximális teljesítményt, amit a kívánt névleges frekvenciára központosítva egy 150 kHz-es sávban mérnek az adás idő alatt a szög és adat jeleknél, meg kell állapítani, figyelembe véve a frekvencia elkülönítést, az adó spektrum teljesítményeket és antenna lefedést, valamint az adott terjedési veszteségeket. Aztán ezt a maximális teljesítményt össze kell hasonlítani a kívánt szög és adat szintekkel annak érdekében, hogy megállapítható legyen, hogy a minimális jel / zaj viszony (SNR) értékek megfelelnek a 3.11.6.1.4 pontban megállapított értékekkel. Ha nem, egy nagyobb frekvencia elkülönítést biztosító csatornát kell választani azért, hogy csökkenjen a maximális nem-kívánt teljesítmény, az adó spektrum jellemzőinek elősegítése érdekében.

9.4 A frekvencia tervezés ismérvének kidolgozása

9.4.1 A frekvencia tervezés ismérvének kidolgozásakor a vezér tényező az MLS földi állomásból kisugárzott spektrum. Amikor a frekvencia tervezés ismérvének kidolgozása a harmadik és a fölötte lévő csatornákra történik, ideális esetben az egyedi MLS földi állomások kisugárzott spektrum kimenetét kell figyelembe venni. Ugyanakkor lehetséges egy adott földrajzi területnél, hogy egy olyan általános MLS adó jelet használjanak, mely megfelel az adott terület követelményeinek.

10. Az MLS-nek különleges helyszíneken történő telepítésére vonatkozó anyag

10.1 Az MLS berendezés teljesítménye a teljes fedésterületi térben

10.1.1 Elfogadott az, hogy bizonyos helyszíneken az MLS-re vonatkozó, a 3. Fejezet 3.11 pontjában meghatározott követelményeket nem lehet kielégíteni a teljes fedésterületi térben a jelre gyakorolt környezeti hatások miatt. Az az elvárás, hogy az ilyen helyszíneken a 3. Fejezet 3.11 pontjának követelményeit legalább az összes közzétett műszeres eljárás útirány-vezetési szektorában egy olyan meghatározott pontig kielégítik, amelyen túl az MLS útirány-vezetése a tervezett üzemeltetéshez már nem használatos. Ahhoz, hogy a megfelelő hatóságoknak segítséget nyújtsanak az ilyen egyedi MLS telepítéseknek a tervezett üzemeltetésekre vonatkozó alkalmassága kezdeti értékeléséhez, a vonatkozó fedési korlátozásokat közzé kell tenni.

11. Az MLS földi berendezés szolgáltatásának integritása és folyamatossága

11.1 Bevezetés

11.1.1 Ennek az anyagnak az a célja, hogy egy leírását adja az MLS földi berendezés szolgáltatási céljainak integritásáról és folyamatosságáról, és útmutatóul szolgáljon a mérnöki tervezéshez és a berendezés rendszer-jellemzőihez. A szolgáltatás integritását és folyamatosságát az üzemeltetési nézőpontból szükségszerűen ismerni kell annak érdekében, hogy döntés szülessen arról az üzemeltetési alkalmazásról, amelyet az MLS alá tud támasztani.

11.1.2 Általánosan elfogadott az, hogy az üzemeltetési céltól függetlenül, a leszállás során a végzetes baleset bekövetkezésének átlagos mértéke az egész rendszer - amelyet a földi berendezés, a légijármű és a légijárművezető képez - hibái, vagy hiányosságai miatt nem haladhatják meg az 1×10^{-7} valószínűséget. Erre a követelményre gyakran általános kockázati tényezőként utalnak.

11.1.3 Egy I. Kategóriájú üzemeltetés esetén, amikor a pontosság és az integritás minimális követelményei szükségesek a leszállás korai szakaszában, annak a felelőssége, hogy a fenti célok biztosításra kerülnek, a légijármű vezetőjére van ráruházva. A III. Kategóriájú üzemeltetéseknél a fenti cél a szükséges, de most ahhoz hozzátartozik az egész rendszer. Ebben az összefüggésben az a legnagyobb fontosságú, hogy törekedjenek a földi berendezés szolgáltatása legmagasabb szintű integritásának és folyamatosságának elérésére. Az integritás annak biztosításához szükséges, hogy a megközelítésben lévő légijármű részére alacsony legyen a hamis útirány-vezetés vételének valószínűsége, a szolgáltatás folyamatossága annak biztosításához szükséges, hogy a légijármű részére a megközelítés végső szakaszaiban kicsi legyen annak valószínűsége, hogy az útirány-vezetési jel 'elveszik'.

11.1.4 Úgy látszik, hogy a különféle üzemeltetési követelményeknek a szolgáltatás különféle integritási és folyamatossági céljai felelnek meg. A G-15. táblázat a szolgáltatás integritásának és folyamatosságának négy szintjét állapítja meg, és írja le, azokat, amelyek azokra az alap eljárásokra alkalmazhatók, ahol a DME nem kritikus alkotóelem.

11.2 A szolgáltatási szintek integritásának és folyamatosságának megvalósítása és megőrzése

11.2.1 Egy integritás hiba akkor fordulhat elő, amikor egy olyan jel kerül kisugárzásra, amely a meghatározott tűréshatárokon "kívül van", illetve pontatlan (egy digitális adat esetében), vagy azért, mert a felügyelő egység nem ismeri fel, vagy azért, mert az ellenőrző áramkörök elmulasztják a hibás jel eltávolítását. Egy ilyen hiba egy veszélyhelyzet részét képezheti, ha nagy hibát eredményez.

11.2.2 Nyilvánvalóan nem az összes integritás hiba veszélyes a megközelítés valamennyi szakaszában. Például a megközelítés kritikus szakaszai során egy jelentős útvonal-követési hibát (PFE) létrehozó észrevétlen hibának különleges jelentősége van, ellenben egy, a biztonsági-vezetési, vagy az azonosító jelekben előforduló észre nem vett jel elvesztés nem fog szükségszerűen veszélyes helyzetet létrehozni. Azok a meghatározási ismérvek azonban, hogy melyik hiba mód lényeges, magukba foglalják az összes olyan veszedelmes hiba körülményt, ami nem kétségbevonhatatlanul nyilvánvaló az automatikus repülési rendszer, vagy a légijármű vezetője részére.

11.2.3 Különösen fontos az, hogy olyan felügyelő rendszerek kerüljenek tervezésre, amelyek biztosítják a hibamentes üzemeltetést a 3. Fejezet 3.11.5.2.3 és 3.11.5.3.3 pontjában leírt Szabványoknak való megfeleléssel. Ez gyakran szigorú tervezési elemzést igényel. A felügyelő rendszer hibái különben lehetővé tehetik a hibás jelek kisugárzását.
Néhány olyan lehetséges körülmény, ami a veszély részét képezheti, a II. és III. Kategóriájú üzemeltetési teljesítményeknél:

a) egy olyan észre nem vett hiba, ami az útvonal-követési hiba (PFE) jelentős növekedését okozza a megközelítést végző légijármű szempontjából nézve;

b) egy észre nem vett hiba a minimális siklópályában, az alap adatszó 2-ben leadva;

c) egy olyan észre nem vett hiba az időosztásos multiplex (TDM) szinkronizálásban, ami egy egymásra tolódást hoz létre; és

d) a teljesítmény olyan csökkenése, ami a kormányzási elmozdulási zajt (CMN) elfogadhatatlan határokra növeli.

11.2.4 A védelem legmagasabb szintje a felügyelő egység és a hozzá kapcsolódó vezérlő rendszer észre nem vett hibájának kockázata ellen szükséges. Ezt úgy lehet elérni, hogy gondosan megtervezik az ilyen előfordulások lehetőségének az alacsony szintre való csökkentését, és elvégzik a felügyelő rendszer teljesítményének időszakos ellenőrzését olyan időközönként, amelyet a tervezési elemzés határozott meg. Egy ilyen elemzést fel lehet használni a rendszer integritás szintjének a minden egyes leszállásra vonatkozó kiszámítására. A következő képletet meghatározott típusú MLS berendezésekre lehet alkalmazni, és egy példát ad a rendszer integritás *I*, meghatározására, az észre nem vett hibás kisugárzású adások valószínűségének *P*, kiszámításából.

$$I = 1 - P$$

$$P = \frac{T^2}{\alpha_1 \alpha_2 M_1 M_2}$$

ahol:
I = integritás;

P = az adó és a felügyelő rendszerben előforduló olyan egyidejű hibák valószínűsége, amelyek észre nem vett hibás sugárzást eredményeznek;

M_1 = adó meghibásodások közötti átlagos idő (MTBF);

M_2 = a felügyelő és a hozzá kapcsolódó vezérlő rendszer meghibásodásai közötti átlagos idő;

$\frac{1}{\alpha_1}$ = az adóban bekövetkező olyan meghibásodások gyakoriságának aránya, amely hibás jelek kisugárzását eredményezte az összes adó hiba gyakoriságához viszonyítva;

$\frac{1}{\alpha_2}$ = a felügyelő és a hozzá kapcsolódó vezérlő rendszer olyan meghibásodási gyakoriságának aránya, amely egy hibás jel kimutatására való képtelenséget eredményezett az összes, a felügyelő és a hozzá kapcsolódó vezérlő rendszer hiba gyakoriságához viszonyítva;

T = a felügyelő és a hozzá kapcsolódó vezérlő rendszer ellenőrzései közötti időtartam (órákban).

Ez a példa képlet egy olyan tartalék nélküli felügyelő rendszer felépítésre alkalmazható, amelynél egy egyértékű T-t alkalmaznak a felügyelő és a hozzá kapcsolódó vezérlő rendszer összes alkotóelemére.

11.2.5 Az integritást illetően, mivel a felügyelő, vagy vezérlő rendszeren belüli veszélyes meghibásodás előfordulásának valószínűsége rendkívüli módon távoli, azért az, hogy egy magasfokú bizonyossággal megállapítsák a szükséges integritás szintet, szükségessé tenne egy olyan többsávos kiértékelési időtartamot, ami a berendezés meghibásodások közötti átlagos idejének (MTBF) meghatározásához szükséges. Az ilyen elnyújtott időtartam elfogadhatatlan, és annak megfelelően a megkívánt integritás szintet csak a berendezés szigorú tervezési elemzésével lehet előre "megjósolni". Azonban az elemzésben a bizonyosság fokát az adó és a felügyelő rendszer funkciója közötti függetlenség kimutatásával lehet elérni. Az adó és a felügyelő rendszer előre megjósolt teljesítményét azután önállóan lehet értékelni, ami jóval valószínűbb becslési időtartamot eredményez.

11.2.6 A meghibásodások közötti átlagos időt (MTBF) és a berendezés szolgáltatásának folyamatosságát az alap felépítési jellemzők és az üzemeltetési környezet 'szabályozza'. Az alap felépítési jellemzők a berendezés alkatrészeinek meghibásodási gyakoriságát és az alkatrészek közötti fizikai kapcsolatot foglalják magukba. A meghibásodási gyakoriság (1/MTBF) és a szolgáltatás folyamatossága nem minden esetben egymással összefüggő, mivel nem minden berendezés hiba fog szükségszerűen egy üzemszünetet eredményezni, mint például egy olyan eset, amikor az adó hibája a készenléti adóra történő azonnali átállást eredményezi. A gyártótól elvárt az, hogy biztosítsa azokat a tervezési részleteket, amik ismeretében lehetővé válik a meghibásodások közötti átlagos időnek és a szolgáltatás folyamatosságának a kiszámíthatósága. A berendezés tervezésénél a legalkalmasabb tervezési technikát, anyagokat és alkatrészeket kell alkalmazni, és szigorú ellenőrzést kell alkalmazni a gyártás során. Alapvető annak biztosítása, hogy a berendezés a gyártó által meghatározott környezeti körülményeken belül működjön.

11.2.7 A szolgáltatás folyamatosságának tervezésénél az az elvárás, hogy az haladja meg az alábbi 12.4 pontban megadottakat egy olyan tűréssel, ami csak megvalósítható. Ennek az okai a következők:

a) az üzemeltetési környezetben tapasztalt meghibásodások közötti átlagos idő gyakran rosszabb annál, mint amit a tervezési számításokkal meghatároznak az üzemeltetési tényezők hatásai miatt;

b) a 12.4 pontban megadott szolgáltatás folyamatossági célok az üzemeltetési környezetben elérendő minimális értékek. Bármilyen ezen értékek fölé történő teljesítmény növekedés fokozza a leszállási üzemeltetések általános biztonságát;

c) a tűréshatár a szolgáltatási cél folyamatossága és az elért "érték" között abból a célból szükséges, hogy csökkentse egy berendezés alkalmasságának a statisztikai bizonytalanság miatt meghatározott szolgáltatási szintje alapján történő téves visszautasítását.

Megjegyzés. - A 3. és 4. szintű szolgáltatás folyamatossági értékek magukba foglalják azt a tényezőt, amivel számításba vették az útirány-vezetés elvesztése esetében a légijármű vezetőjének a végzetes baleset elkerülési képességét. Kívánatos, hogy ezt a tényezőt a gyakorlatilag megvalósítható maximális mértékben lecsökkentsék ahhoz, hogy a lehetséges legnagyobb szolgáltatás folyamatossági szintet elérjék a 3. és 4. szintű berendezéseknél.

11.2.8 A tapasztalatok azt mutatják, hogy gyakran különbség van a szolgáltatás folyamatosságának számított és az üzemeltetési környezetben észlelt értékei között, egyrészt azért, mert a berendezés teljesítménye eltérhet a számított értéktől, másrészt az üzemeltetési tényezők hatása miatt, azaz a repülőtéri környezet, a barátságtalan időjárási körülmények, az energiaellátási problémák, valamint a karbantartás minősége és gyakorisága stb. miatt. Ezen okokból azt ajánljuk, hogy a berendezés meghibásodások közötti átlagos idejét és a szolgáltatás folyamatosságát egy üzemeltetési környezeti kiértékeléssel erősítsék meg. A szolgáltatás folyamatosságát az üzemszünetek közötti átlagos idővel lehet kiértékelni, ahol az üzemszünetet a térbeli-jel bármilyen előre nem várt megszűnéseként lehet meghatározni. Ezt a teljes berendezési működőképes állapotnak az üzemeltetési hibákkal történő elosztásával kell kiszámítani. A szolgáltatás 2., 3., vagy 4. szintű integritására és szolgáltatási folyamatosságára a kiértékelési időtartamnak elegendő hosszúságúnak kell lenni ahhoz, hogy a megkívánt szintnek a magasfokú bizonyossággal való elérését meghatározzák. Annak meghatározásához, hogy egy egyedi berendezés működési jegyzőkönyvei beigazolják-e a 2., 3., vagy 4. szint kijelölését, a következő tényezők szakszerű megfontolásai szükségesek:

a) a működési jegyzőkönyvek és az egy megfelelő időtartamon keresztül megalapozott rendszer-felhasználási tapasztalatok;

b) az ilyen típusú berendezésre megállapított átlagosan elért üzemszünetek közötti átlagos idő (MBTO); és

c) a meghibásodások gyakoriságának /irányzata/ trendje.

11.2.9 Az elfogadás/elutasítás megbízhatóság jellemzően elfogadott foka a 60 százalék. Az MLS szolgáltatási szintjétől függően ez eltérő értékelési időtartamokat eredményezhet. A repülőtéri környezet hatásának értékelésénél jellemzően egy egy-éves időtartamú minimális kiértékelési időtartam szükséges egy meghatározott repülőtéren. Ennek az időtartamnak a lecsökkentése az olyan esetekben lehetséges, ahol az üzemeltetési környezet jól ellenőrzött és egy másik, már "bizonyított" telepítéshez hasonló. Az azonos típusú és hasonló üzemeltetési és környezeti körülmények melletti üzemeltetésre később telepített berendezésnél azután eltérő berendezés értékelési időtartamok következhetnek. Jellemzően ezekre a későbbi telepítésű berendezésekre a minimális időtartamok a 2. szolgáltatási szintre 1600 óra, a 3.szolgáltatási szintre 3200 óra és a 4.szolgáltatási szintre legkevesebb 6400 óra. Ahol több egyforma rendszert üzemeltetnek hasonló körülmények mellett, ott lehetséges az, hogy az értékelést az összes rendszer halmozott üzemeltetési óráira alapozzák. Ez egy lecsökkentett értékelési időtartamot eredményez.

11.2.10 Az értékelési időtartam alatt el kell dönteni azt, tervezési hiba okozta-e az egyes leállásokat, vagy egy olyan alkatrész hibája, amelynek ez a szabvány meghibásodási gyakorisága. A tervezési hibákhoz tartoznak például azok az üzemi alkatrészek, amelyek az előírásaikon túli tartományban működtek (túlmelegedés, túláram, túlfeszültség stb. körülmények).
Ezeket a tervezési hibákat úgy lehet kezelni, hogy az üzemeltetési körülményeket visszaveszik az alkatrész szabvány üzemeltetési körülményeire, vagy úgy, hogy az alkatrészt kicserélik egy olyannal, ami az üzemeltetési körülményeknek jobban megfelel. Ha a tervezési hibát ily módon kezelik, akkor az értékelést tovább lehet folytatni, és ezt a leállást nem kell számolni, alapfeltételként elfogadva azt, hogy ez a tervezési hiba - nagy valószínűséggel - nem fog megismétlődni. Ugyanez alkalmazható bármely olyan eset miatti leállásra, amelyet az üzemeltetési körülmények végleges változtatásával csökkenteni lehet.

11.2.11 Egy adott telepítésű berendezés működése kiértékelésének alkalmas módszere az, hogy rögzítik a hibákat, és kiszámítják a berendezés utolsó öt - nyolc hibájának üzemszünetek közötti /MTBO/ átlagos idejét. Erre a módszerre egy jellemző rögzítési módot ad meg a
G-35A és a G.35B ábra.

11.2.12 A berendezés értékelése során és az üzemeltetési szolgálatba állítását követően folyamatosan jegyzőkönyvezni kell az összes berendezés hibát vagy üzemszünetet azért, hogy megerősítsék a kívánt szolgáltatási folyamatosság fenntartását.

Megjegyzés. - Ha egy berendezéshez tartalék, vagy készenléti egységek szükségesek a kívánt szolgáltatási folyamatosság eléréséhez, akkor egy olyan rendszer szükséges, mint ami a 11.3.4 pontban leírásra kerül, annak biztosításához, hogy a készenléti berendezés rendelkezésre álljon, amikor szükséges.

11.3 Az integritást és a szolgáltatási folyamatosságot érintő kiegészítő szempontok

11.3.1 A III. Kategóriájú üzemeltetésekhez elengedhetetlenül szükséges szigorúbb integritási és szolgáltatás folyamatossági követelmények szükségessé teszik azt, hogy a berendezéseknek kielégítő biztosítékuk legyen a hibákkal szemben. A földi berendezés megbízhatóságának nagyon magas értékűnek kell lenni, és ahhoz, hogy a megközelítés kritikus szakasza és a leszállás biztosítva legyen, egy földi berendezés hiba nem ronthatja el a biztonságot akkor, amikor a légijármű egy olyan magasságon, vagy helyzetben van, hogy képtelen egy biztonságos helyesbítő tevékenységet végrehajtani. A meghatározott határértékeken belüli teljesítményt nagy valószínűséggel biztosítani kell. A berendezés megbízhatóságát a meghibásodások közötti átlagos időben (MTBF) kifejezve tisztán arra a rendszer alapú meghibásodás valószínűségre kell vonatkoztatni, amely a teljes térbeli-jel bármilyen jellemzőjére hatással lehet.

11.3.2 A következő kialakítás példát ad egy olyan tartalékolt berendezési elrendezésre, ami valószínűleg megfelel a 3. és 4. szintű integritási és szolgáltatás folyamatossági céloknak. Az oldalszög adó berendezést két adó és a hozzá kapcsolódó - a következő funkciókat ellátó - felügyelő rendszer alkotja:

a) megfigyeli, hogy a fő adó és az antenna-rendszer üzeme az előírt határértékeken belül van-e a több felügyelő egység közötti többségi választás eszközével; és

b) a készenléti berendezés felügyeletével.
11.3.2.1 Amikor a felügyelő rendszer a berendezések valamelyikét 'kiselejtezi', akkor a berendezés szolgáltatási szintjének folyamatossága le fog csökkenni azért, mert a többi berendezés hibájából bekövetkező jel megszűnés valószínűsége meg fog növekedni. A teljesítmény változást automatikusan ki kell jelezni a távvezérlő helyeken.

11.3.2.2 Egy, az oldalszög adóhoz alkalmazottal megegyező felügyelő rendszer kialakítást kell alkalmazni a magassági szög adó berendezésnél.

11.3.3 A fenti példában a berendezésnek magába kell foglalni egy olyan felszerelést, ami lehetővé teszi a felügyelő rendszer ellenőrzéseit a gyártó által meghatározott, a gyártó tervezési elemzéséből következő időközönként, a szükséges integritási szint elérésének biztosítására. Az ilyen ellenőrzések, amelyek kézi, vagy automatikus ellenőrzések lehetnek, azt az eszközt biztosítják, amely megvizsgálja a felügyelő rendszer pontos működését, beleértve az ellenőrző áramköröket és az átváltó kapcsoló rendszert is. Az a kívánatos, hogy ezeket az ellenőrzéseket olymódon hajtsák végre, hogy ne legyen megszakítás az üzemeltetési szolgáltatásban. Egy automatikus felügyelő rendszer integritás vizsgálat megvalósításának az az előnye, hogy azt jóval gyakrabban végre lehet hajtani, és ezáltal magasabb szintű integritás érhető el.

11.3.4 A berendezés működésének az elsődleges áramellátás hibája miatti megszakadását egy megfelelő készenléti áramellátás biztosításával lehet elkerülni, például telepekkel, vagy "szünetmentes" generátorokkal. Ilyen feltételek mellett a berendezés képes lesz a folyamatos működésre azon időtartam alatt, amikor a légijármű a megközelítés kritikus szakaszaiban lehet. Következésképpen a készenléti áramellátásnak megfelelő kapacitással kell rendelkeznie ahhoz, hogy a szolgáltatást legalább két percen keresztül fenntartsa.

11.3.5 A rendszer kritikus alkotó részeinek meghibásodására - mint például az elsődleges áramellátás hibájára - vonatkozó figyelmeztetéseket kell adni, ha a hiba hatással van az üzemi felhasználásra kijelölt vezérlő pontokra.

11.3.6 Abból a célból, hogy az olyan berendezések hibáit csökkentsék, amelyek a felügyelő rendszer tűrési határértékeinek közelében üzemelnek, a felügyelő rendszer részére hasznos lehet az, hogy egy olyan rendszert iktassanak be, ami egy előzetes riasztó figyelmeztető jelet ad a kijelölt vezérlő pontokra akkor, amikor az ellenőrzött paraméterek elérik azt a határt, ami a felügyelő rendszer figyelmeztető jelzési határértékeinek a 75 százalékával egyenlő.

11.3.7 A térbeli-jel integritásának az olyan csökkenéssel szembeni védelmét is figyelembe kell venni, amit az MLS frekvenciasávra ható külső elektromágneses interferencia okozhat, vagy az MLS jelek visszasugárzásából eredhet.

11.3.8 Egy területi felügyelő rendszer további védelmet tudn nyújtani azáltal, hogy figyelmeztető jelzést biztosít az MLS antenna fizikai mozgása miatt bekövetkező megnövekedett útvonal-követési hibahatárok esetén, illetve védelmet nyújt belső, felügyelő rendszerbeli hibák ellen.

11.3.9 Általában véve az ellenőrző rendszerek berendezéseinek tervezése azon az alapelven nyugszik, hogy folyamatosan megfigyeljék a kisugárzott térbeli-jelet a fedésterületi tér meghatározott pontjaiban azért, hogy biztosítva legyen a 3. Fejezet 3.11.5.2.3 és 3.11.5.3.3 pontjaiban meghatározott Szabványoknak való megfelelés. Jóllehet, az ilyen felügyelet bizonyos mértékben jelzést biztosít arról, hogy a térbeli-jel a fedésterületi térben az összes többi ponton is hasonlóképpen a tűréshatáron belül van, ez mégis nagymértékben csak következtetés. Ennek megfelelően elengedhetetlen az, hogy szigorú ellenőrzéseket hajtsanak végre rendszeres időközönként azért, hogy biztosítsák a térbeli-jel integritását a teljes fedésterületi téren belül.

11.3.10 Egy, a fenti 11.3.2 pontban leírtakkal megegyező berendezés rendszer és a fenti 11.3.5, 11.3.6, 11.3.7, 11.3.8 és 11.3.9 pontokban leírt útmutatások alkalmazását lehet szabályszerűen elvárni a 2. szintű integritás és szolgáltatás folyamatossági célok eléréséhez.

12. Az MLS megközelítési oldalszög, magassági szög és a DME földi berendezések osztályozása

12.1 A következő pontokban leírt osztályozási rendszernek az a célja, hogy időben szűkre szabott módon azonosítsa azokat a nélkülözhetetlen információkat, amelyeket a műszeres eljárások tervezői, a légijármű üzemeltetők és a légiforgalmi szolgálatok használnak fel egy meghatározott MLS berendezés teljesítményére vonatkozóan. A tájékoztatások a légiforgalmi tájékoztató kiadványokban (AIP) kerülnek közzétételre.

12.2 Az MLS berendezés teljesítményre vonatkozó információk magukba kell, hogy foglalják:

a) az oldalszög arányos útirány-vezetési szektor határértékeit;

b) a függőleges útirány-vezetés határértékeit ;

c) az útirány-vezetési jelnek a futópálya hosszában való rendelkezésre állását; és

d) az útirány-vezetési jelet (oldalszög, magassági szög és DME).

12.3 Az egy meghatározott MLS berendezésre vonatkozó információkat magába foglaló osztályozási rendszert a következő formátumokat felhasználva kell meghatározni:

a) *Az oldalszög arányos útirány-vezetési szektor határértékei.* Ez az adatmező egy meghatározott MLS-re az oldalszög arányos útirány-vezetési szektor határvonalait azonosítja úgy, ahogy az az alap adatszó 1-ben meghatározásra került. A két értéket egy kettőspont választja el (XX:YY), és jelzi a szektor határértékeket úgy, ahogy az a megközelítés irányából látható; az első érték a szektor határérték a nulla fokos oldalszögtől balra és a második érték a szektor határérték a nulla fokos oldalszögtől jobbra.

b) *Függőleges útirány-vezetési határérték.* Ez az adatmező, ami közvetlenül az oldalszög határértékek után került elhelyezésre (formátum XX:YY/ZZ m (vagy XX:YY/ZZ láb)), azt a minimális magasságot (méter-ben, vagy láb-ban) jelenti a végső megközelítési szakaszban a minimális siklópálya (MGP) mentén a futópálya küszöbe felett, amelynek megfelelően a rendszer megfelel a 3. Fejezet 3.11 pontjában meghatározott jel jellemzőknek.

c) *Futópálya útirány-vezetés.* A D, vagy E betűk (ahogy az a “G"- Melléklet 1. részében meghatározott) jelzik azokat a pontokat, ameddig az oldalszög útirány-vezetés a futópálya hosszában megfelel a 3. Fejezet 3.11 pontjában meghatározott jel jellemzőknek (formátum XX:YY/ZZ/E). Ha az útirány-vezetési jel a futópálya hosszában nem felel meg a fent említett jellemzőknek, akkor egy vonást (—) kell a formátumban használni.

d) *Az útirány-vezetési jel megbízhatósága.* Az 1, 2, 3, vagy 4-es szám jelzi az útirány-vezetési jel integritásának és szolgáltatási folyamatosságának szintjét (G-15. táblázat). Az A betű, ami a 3., vagy 4. szint meghatározás után van elhelyezve, azt jelzi, hogy a magassági szög és a DME / P céljai egyenlő értékűek az oldalszög céljaival, a G-15. táblázat 6. Megjegyzésének megfelelően (formátum: XX:YY/ZZ/E/4).

1. Megjegyzés. - Ahol a DME nem szükséges a tervezett MLS üzemeltetésekhez, ott nem kell a DME /P megbízhatóságát az MLS osztályozásba beépíteni.

2. Megjegyzés. - Ahol egy 'feljavított' magassági szög és / vagy DME / P megbízhatóság szükséges a G-15. táblázat 6. Megjegyzésének megfelelően a tervezett MLS / RNAV üzemeltetésekhez, ott a 'feljavított' magassági szög és / vagy DME / P megbízhatóságot be kell építeni az MLS osztályozásba.

12.3.1 Bármilyen, az Annex 10 Szabványai alá történő jel csökkenést, vagy a korábbiakban közzétett teljesítmény alá csökkenést a megfelelő hatóság közzé kell, hogy tegye (2. Fejezet 2.1.2 pont és a fenti 10. rész).

12.4 A G-15. táblázat az MLS alap- és az MLS / RNAV üzemeltetések szolgáltatás folyamatossági és integritási céljait adja meg.

Megjegyzés. - A meghatározott MLS üzemeltetésekre vonatkozóan az a cél, hogy az integritás és a szolgáltatás folyamatossága jellemzően a következőkkel társuljon:

1) a 2. szintű teljesítmény célja az, hogy az MLS berendezést az olyan alacsony látástávolságú üzemeltetések alátámasztására használják, ahol az MLS irányvezetést a leszállási szakasz helyzet tájékoztatásánál látásos segédeszközökkel egészítik ki. Ez a szint kívánatos célja az I. Kategóriájú üzemeltetéseket alátámasztó berendezéseknek;

2) a 3. szintű teljesítmény célja az, hogy az MLS berendezést olyan üzemeltetések alátámasztására használják fel, amelyek magasszintű bizalmat helyeznek az MLS által nyújtott irány-vezetésre egészen a földetérési pontig. Ez a szint a II. Kategóriájú és a III.A. Kategóriájú üzemeltetéseket alátámasztó berendezések szükségletének jellemzője; és

3) a 4. szintű teljesítmény célja az, hogy az MLS berendezést az olyan üzemeltetések alátámasztására használják fel, amelyek magasszintű bizalmat helyeznek az MLS által nyújtott irányvezetésre egészen a földetérési pontig és a leszállás utáni kifutás-kigurulás során. Ez a szint alapjában a III. Kategóriájú üzemeltetések teljes sorának szükségleteire vonatkozik.

12.5 Az MLS berendezés osztályozásának következő példája:

40 : 30 / 50 láb / E / 4A

azt a rendszert jelöli, amelynél:

a) az arányos útirány-vezetési szektor a nulla fokos oldalszögtől 40 fok balra és 30 fok jobbra;

b) a függőleges útirány-vezetés a futópálya küszöbe feletti 50 láb magasságig alkalmazható;

c) a leszállás utáni kifutási útirány-vezetés az MLS E-pontig alkalmazható; és
d) az integritás és a szolgáltatás folyamatossága 4. szintű úgy, hogy a magassági szög és a DME / P céljai megegyeznek az oldalszögével.

13. Számított középvonalas megközelítések

13.1 Általános rész

13.1.1 A számított középvonalas megközelítések az alábbiak szerint figyelembe véve egy számított, a futópálya középvonala mentén elhelyezkedő pályán alapulnak, ott, ahol az oldalszög antenna nem a futópálya meghosszabbított középvonalában van elhelyezve. A számított középvonalas megközelítés legegyszerűbb formája az, amelynél a névleges útirány a nulla-fokos oldalszöggel párhuzamos. Abból a célból, hogy egy MLS / RNAV üzemeltetést végrehajtsanak, az alap MLS vevőben rendelkezésre állónál nagyobb 'képességű' berendezés szükséges.

13.1.2 A számított középvonalas megközelítések az MLS elsődleges futópályára azoknál a futópályáknál kerülnek végrehajtásra, amelyeknek az MLS földi berendezéssel való ilyen összefüggése a kiegészítő adatszavakban azonosításra kerül.

13.1.3 Amikor a végső szakaszt az MLS fedésterületi tere magába foglalja, akkor a számított középvonalas megközelítéseket egy egyenes végső megközelítési szakasz mentén lehet végrehajtani, egy süllyedési gradiensen, egészen az elhatározási magasságig (DH) süllyedve.
A számított középvonalas megközelítések olyan elhatározási magasságokat eredményezhetnek, amelyek felette vannak annak az elhatározási magasságnak, ami egy, a középvonallal egybeeső MLS megközelítéssel elérhető.

13.2 A számított középvonalas megközelítés hiba összegzése

13.2.1 A Légiforgalmi Rádiótechnikai Bizottság /RTCA/ (RTCA/DO-198) írja le az MLS területi navigációs (RNAV) berendezés teljes rendszer hiba összegzését. Ez a hiba összegzés a következő hozzájáruló tényezőket foglalja magába:

a) a földi berendezés teljesítménye;

b) a fedélzeti jelátalakító teljesítménye;

c) a földi berendezés geometriai hatása;

d) az MLS / RNAV számítógép számítási hibája; és

e) a repülési vezetési technikai hiba (FTE).

13.2.2 A fenti hiba-összetevőket a repülési vezetési technikai hiba /FTE/ kivételével teljes helyzet-hibának nevezik. Az MLS megközelítési vonatkozási ponttól 3,7 km-en (2 tengeri mérföld) belül a magengedett oldalirányú teljes helyzet-hiba az MLS / RNAV berendezésre az MLS alap-pont feletti 60 méteres (200 láb) magasságú helyzetben egy 3-fokos magassági szögön és egy 3 000 méteres (10 000 láb) hosszúságú futópályánál 15 m (50 láb) (lásd az alábbi megjegyzést).
Hasonlóképpen a megengedett függőleges teljes helyzet-hiba 3,7 m (12 láb) ugyanabban a helyzetben. A teljes helyzet-hiba összegzés egy része az MLS / RNAV számítógép teljesítményére (számítási hiba) van fenntartva. Az MLS megközelítési vonatkozási ponttól 3,7 km-en (2 tengeri mérföld) belül, a hiba összegzésnek a számítási hibára fenntartott része ± 0,6 m (2 láb) mind oldalirányban, mind magasságban. A 13.5 pontban bemutatott eredmények ennek a számítási pontossági követelménynek a teljesítésétől függőek.

13.2.3 A megengedett oldalirányú teljes helyzet-hibára a négyzetes középérték módszert alkalmazva - az MLS / RNAV számítógép teljesítményt kihagyva - az eredmény ± 15 méternél (50 láb) valamivel kevesebb. Hasonlóképpen a megengedett függőleges teljes helyzet-hiba - a számítási hibát kihagyva - valamivel kevesebb, mint ± 3,7 méter (12 láb). Ennélfogva a földi rendszer teljesítménye, a fedélzeti jelátalakító teljesítménye, valamint a földi rendszer geometriájának hatása miatti összegzett hiba várhatóan nem haladja meg a ± 15 métert (50 láb) oldalirányban és a 3,7 métert (12 láb) függőlegesen az előbb leírt helyzetben. Ezt az információt és alapfeltételt a földi és a fedélzeti jelátalakító teljesítményére felhasználva, megkapható a maximális megengedhető oldalszög és magassági szög antenna eltolt /ordináta/ helyzet (geometriai hatás) a futópálya középvonalától.

13.2.4 A kormányzási elmozdulási zaj /CMN/ nem haladja meg a ± 7,3 métert (24 láb) oldalirányban és a ± 1,9 métert (6,3 láb) függőlegesen, vagy a lineáris megfelelőjét a ± 0,1 fokot; amelyik a kevesebb. A lineáris értékek a következő névleges antenna elhelyezésen alapulnak: oldalszög antenna - futópálya küszöb távolság 3 300 méter (11 000 láb) és alap-pont - küszöb távolság 230 méter (760 láb), 3 fokos magassági szögnél. Az MLS megközelítési vonatkozási ponttól 3,7 km-en (2 tengeri mérföld) belül a kormányzási elmozdulási zaj /CMN/ összegzésen belül a számítási hibára fenntartott rész 1,1 méter (3,5 láb) oldalirányban és 0,6 méter (2 láb) függőlegesen.

Megjegyzés. - Az összes hiba 95 százalékos hibát jelent.

13.3 Telepítési és pontossági megfontolások

13.3.1 Elméleti és üzemeltetési elemzések kimutatták azt, hogy több tényezőnek lesz hatása az oldalszög antenna oldalirányú eltolt (ordináta) helyzete értékének nagyságára, megengedhető és még elérhető az az oldalirányú és függőleges helyzet pontosság, ami a 13.2 pontban került meghatározásra.

13.3.2 *Az oldalszög és a magassági szög antennák közötti távolság*

13.3.2.1 Egy adott oldalszög antenna oldalirányú eltolt helyzetnél, egy 'rövid' oldalszög - magassági szög antenna távolság viszonylag nagy oldalszög szögeket eredményez a megközelítési vonatkozási pont közelében lévő helyzeteknél. Ennek eredményeként, a DME-től származó hiba hozzájárulás nagy, és az oldalirányú pontosság elfogadhatatlanul lecsökkenhet. Egy olyan futópályánál, ahol 'nagy' az oldalszög antenna oldal-irányú eltolt helyzete és 'rövid' az oldalszög - magassági szög antenna távolsága, inkább egy DME / P alkalmazására lehet szükség, nem pedig DME / N-re, azért, hogy a szükséges oldalirányú pontosság elérésre kerüljön.

13.3.3 *Oldalszög pontosság*

13.3.3.1 A 13.5 pontban bemutatott oldalszög antenna eltolt helyzet (ordináta) határértékek a ± 6 méteres (20 láb) oldalszög útvonalkövetési hiba pontossági előíráson alapulnak (lásd a 3. Fejezet 3.11.4.9.4 pontját). Az ajánlott ± 4 méteres (13,5 láb) oldalszög pontossági előírás nagyobb oldalszög antenna eltolt helyzetet tesz lehetővé és még mindig elérhető lesz a szükséges számított helyzet pontosság az elhatározási magasságnál /DH/. Az oldalszög pontosságra elfogadott az, hogy a 3. Fejezet 3.11.4.9 pontjában leírtaknak megfelelően csökken.

13.3.4 *DME pontosság*

13.3.4.1 A helyzet-meghatározásban kisebb hibákat eredményez az, ha DME / P berendezést használnak, és a végső megközelítési szakasz az MLS megközelítési referencia ponttól mért 9,3 km-en (5 tengeri mérföld) belül van. Két DME / P végső megközelítési mód pontossági szabvány van ebben a körzetben. Amikor a DME / P berendezésre azt az oldalszög antenna eltolt helyzetű /ordináta/ értéket alkalmazzák, ami a 13.5 pontban bemutatásra kerül, akkor az az 1. pontossági Szabványon alapuló végső megközelítési módot adja. Nagyobb oldalszög antenna eltolt helyzetű /ordináta/ értékeket lehet megengedni akkor, ha a DME / P berendezésre a 2. pontossági Szabványt kielégítő végső megközelítési módot alkalmazzák. A DME / P 1.Szabványú végső megközelítési mód távolság-mérési pontosságára az az elfogadott, hogy a 3. Fejezet 3.5.3.1.3.4 pontjában leírtak és a B-táblázatban megadottak szerint csökken. A DME / N-re az az elfogadott, hogy a 3. Fejezet 3.5.3.1.3.2 pontjában leírtak szerint csökken.

13.3.5 *A magassági szög információnak az oldalirányú helyzet kiszámításában való felhasználása*

13.3.5.1 Általában, az az oldalirányú helyzet számítás, ami kizárja a magassági szög információt, elegendő lesz az elsődleges futópályára végrehajtott számított középvonalas megközelítésekhez. Ha a magassági szög információ nem használatos az oldalirányú számításokban, akkor az oldalirányú hiba megnövekszik. Ez a hiba az oldalszög szög, a magasság és a csökkenő távolság függvényében növekszik. A 13.5 pontban bemutatott megengedhető oldalszög antenna eltolt helyzetek lecsökkennek akkor, ha a magassági szög tájékoztatások nem használatosak az oldalirányú számításokban. A magassági szög pontosságra elfogadott az, hogy a 3. Fejezet 3.11.4.9 pontjában leírtaknak megfelelően csökken.

13.4 A berendezések figyelembevétele

13.4.1 A fedélzeti jelátalakító, az MLS földi berendezés és az MLS / RNAV fedélzeti elektronika teljesítménye gyakorol hatást a számított középvonalas megközelítések alkalmazási tartományára. A 13.5 pontban bemutatott információk a következő berendezések figyelembevételén alapszik.

13.4.2 *Fedélzeti jelátalakítók*

13.4.2.1 Elfogadott az, hogy a vevő dekódolni fogja az összes, az MLS számított középvonalú megközelítéshez szükséges kiegészítő adatszót, kivéve azt, ha az adatszavakban lévő információ más repülési elektronikai forrástól - a kiegészítő adatszavakhoz szükségessel - megegyező pontossággal és integritással rendelkezésre áll. A digitális MLS szög adatok és távolság adatok szükségesek az oldalirányú és a függőleges helyzet kiszámításához. A szög adat kvantálás 0,01 fok. A távolság kvantálás 2,0 m (0,001 tengeri mérföld).

13.4.3 *Területi navigációs (RNAV) számítások*

13.4.3.1 Nincs alapfeltétel elfogadva arról, hogy az RNAV helyzet-számítás hol kerül elvégzésre. A számított középvonalas megközelítés hiba összegzésének egy része a számítási hiba részére került fenntartásra. Ez lehetővé teszi a rugalmas algoritmus alkalmazást.

13.4.4 *A megengedhető oldalszög adó antenna eltolt helyzet /ordináta/ kiszámítási technikák*

13.4.4.1 A Légiforgalmi Rádiótechnikai Bizottság (RTCA) (RTCA/DO-198 D-Függelék) több különböző helyzet-meghatározó algoritmust állapít meg. A különböző algoritmusok különféle földi berendezés elhelyezést tudnak kezelni. Az az algoritmus, ami arra a célra tervezett, hogy bármilyen földi berendezés elrendezést kezeljen, az RTCA 12-eset algoritmus. A megengedhető antenna oldalirányú helyzet értékeket a Monte Carlo szimulációs technika alkalmazásával nyerték. Az eredményeket még egy közvetlen elemzési módszer alkalmazásával is megkapták. Az elemzési módszer a maximális MLS szög és távolság hibák geometriai transzformációs módszerét alkalmazza a rendszer teljesítmény meghatározásához. A Monte Carlo technika az MLS / RNAV rendszer utánzásán keresztül egy statisztikai módszerként használatos a rendszer teljesítmény meghatározásához.

13.4.4.2 *A helyzet-meghatározás lehetséges korlátozásai.* A földi berendezés geometriájától függően a helyzet-meghatározó algoritmusokra a lehetséges összetett megoldások tere áll fenn. Az összetett megoldások tere a magassági szög antennának és a DME válaszadónak a futópályához viszonyított elhelyezésétől és a számított megközelítési útvonaltól függ. A legkihangsúlyozottabb hatás akkor fordul elő, amikor a DME válaszadó a megközelítési útvonal elhatározási magasság (DH) pontja és a magassági szög adó antenna közötti területen helyezkedik el. A helyzet bizonytalanságát akkor lehet feloldani, amikor a DME válaszadót a megközelítési irány felől nézve a magassági szög adó antenna mögé helyezik el. Amikor a DME válaszadó a magassági szög antenna előtt van elhelyezve, akkor nem lehet a helyzet bizonytalanságot feloldani.

13.4.5 *A földi berendezés geometriája*

13.4.5.1 A névleges földi berendezés geometria a földi összetevők relatív helyzetében kifejezve a G-29. számú ábrán került lerajzolásra. A DME / P válaszadóra itt alapfeltétel az, hogy a megközelítési oldalszög adó antennával van együtt telepítve. Amikor DME / P földi berendezés nem áll rendelkezésre, akkor a DME / N válaszadóra alapfeltétel az, hogy az MLS megközelítési oldalszög adó és magassági szög adó antennák között van elhelyezve.

13.4.5.2 A DME / N által létrehozott viszonylag nagy hiba miatt, a DME / N válaszadó elhelyezésének nincs jelentős hatása a számított megengedhető oldalszög adó antenna oldalirányú eltolt elhelyezésre. Ez lehetővé teszi a DME / N berendezésnek az oldalszög adó és a magassági szög adó antennák között egy nagy területen belüli elhelyezését. Hasonlóképpen a magassági szög adó antenna oldalirányú eltolt helyzetének is kicsi lesz a hatása.

13.5 A megengedhető megközelítési oldalszög adó antenna eltolt helyzetek az elsődleges futópályára számított középvonalas megközelítéseknél

13.5.1 *DME eredmények*

13.5.1.1 A maximális oldalszög adó eltolt helyzet, a körülmények egy adott sorozatára azt a legnagyobb oldalirányú eltolt helyzetet jeleni, amit nem lehet túllépni a 13.2 pontban megadott számított középvonalas megközelítés hiba összegzésben. A DME / P eredmények az oldalszög adó és a magassági szög adó távolság függvényeként vannak bemutatva. A DME / P berendezéssel megengedett oldalszög adó antenna oldalirányú eltolt helyzeteket a G-30. számú ábra mutatja be.

13.5.1.2 Egy adott oldalszög adó - magassági szög adó távolságra, az oldalszög adó antennát az árnyékolt terület bármely helyére el lehet helyezni, és a létrejövő számított középvonalas megközelítés kielégíti a 13.2 pont követelményeit.

13.5.1.3 Eredményeket kaptak akkor is, amikor DME / N távolságmérési pontosságokat alkalmaztak. Ezeket az eredményeket a G-31. számú ábra mutatja be.

13.6 Alacsony látástávolság esetén végrehajtott megközelítések

13.6.1 *A lehetséges alkalmazások*

13.6.1.1 Az alacsony látástávolság esetén végrehajtott számított középvonalas megközelítés lehetséges alkalmazását az elsődleges műszeres futópályákra való üzemeltetésekre lehet korlátozni azon geometriai megfontolások miatt, amit a kielégítő pontosság elérése magában foglal. Az elsődleges műszeres futópályához történő felhasználások, ahol a számított középvonalas megközelítési képesség hasznos lehet, azok, ahol az oldalszög adónak a futópálya középvonalától oldalirányú eltolt helyzetű telepítését a "szigorú" telepítési korlátozások teszik szükségessé. Ezek lehetnek azok az oldalirányú eltolt helyzetű alkalmazások, ahol az alacsony látástávolság esetén végrehajtott üzemeltetéseket előnyösnek tekintik.

13.6.1.2 Az elvárt fedélzeti felszerelésnek az ilyen alacsony látástávolságú üzemeltetések számított középvonalas megközelítéseire nem-számított magassági útirány-vezetést kell felhasználni (alapfeltételként elfogadva azt, hogy a magassági szög adó antenna szabályszerűen van telepítve), és az oldalirányú útirány-vezetést az oldalszög (beleértve az MLS telepítési adatokat is, amelyeket az alap és a kiegészítő adat funkciók foglalnak magukba), valamint a DME / P válaszadótól származó távolság adatokból kell származtatni.

13.6.2 *A fedélzeti rendszer teljesítménye*

13.6.2.1 Biztonsági-kritikus, a nem-számított középvonalas alacsony látástávolságú megközelítések útirány-vezetéséhez kapcsolódó szoftvert nagyrészt magukba foglalnak az MLS vevők. A számított középvonalas megközelítéseknél a DME kérdező adó-vevőt és a navigációs számításokat is számításba kell venni. A biztonsági-kritikus szoftvert ezekre a funkciókra meg kell tervezni, ki kell dolgozni, dokumentálni kell és ki kell értékelni.

13.6.2.2 A szükséges algoritmusok viszonylag egyszerűek, és nem okoz semmilyen alkalmassági elfogadási nehézséget. Azonban a repülőgép vezérlő számítógép rendszerekkel (FMS) szerzett tapasztalatok azt jelzik, bonyolult lenne egy jelenlegi repülőgép vezérlő rendszeren (FMS) belül egy biztonsági-kritikus funkció alkalmasságát hitelesíttetni. A jelenlegi repülőgép vezérlő rendszerek (FMS) felépítése nincs úgy részekre osztva, hogy az lehetővé tegye a különféle funkcióknak a különféle kritikussági szintű hitelesítését, egy repülőgép vezérlő rendszer (FMS) mérete és összetettsége eleve kizárja a teljes repülőgép vezérlő rendszer számítógép biztonsági-kritikus hitelesítését. Következésképpen, a repülőgép vezérlő rendszer berendezéshez valamilyen alternatív felszerelést lehet számításba venni az alacsony látástávolságú üzemeltetésekre tervezett számított középvonalas berendezés alkalmassághoz (azaz a robotpilótába beépítetten, vagy az MLS vevőbe beépítetten). Ezeknek az alternatív rendszereknek olyan útirány-vezetési kimenetet kell biztosítaniuk, mint amilyen kimeneti jellemzőkkel a szabályszerű egyenes megközelítések rendelkeznek.

13.6.3 *A földi rendszer teljesítménye*

13.6.3.1 A fenti 13.3.5 pontban alapfeltételként elfogadott felszerelésre alapozva a magassági szög útirány-vezetés pontosan ugyanazon a módon kerülne felhasználásra, ahogy az az alap MLS megközelítéseknél történik. Ennek megfelelően a magassági szög adó földi berendezés integritása és szolgáltatási céljainak folyamatossága változatlan marad, annak megfelelően, ami a G-15. táblázatban már megadásra került. Az oldalirányú útirány-vezetésre a G-15. táblázatban az oldalszögre megadott integritási és a szolgáltatás céljainak folyamatossága követelményeket a kombinált oldalszög és DME rendszerre kellene alkalmazni, és az mindkettő céljaira szigorúbb követelményt eredményez annál, mint ami az alap MLS üzemeltetésekhez szükséges. Azonban egy alacsony látástávolságú számított középvonalas üzemeltetést a 30 méteres (100 láb) elhatározási magasságig el lehet érni egy olyan földi berendezés felhasználásával, amely kielégíti a G-15. táblázatba foglalt 4. szintű célokat.

13.6.4 *Pontosság*

13.6.4.1 Az MLS / RNAV alá fogja támasztani a számított repülési pályákat az I. Kategóriájú elhatározási magasságokig azokra az elsődleges futópályákra, amelyeknek a korlátozásai olyanok, mint ami a G-30. számú ábrán meghatározásra került. Azonkívül bizonyos meghatározott körülmények esetén az MLS / RNAV kielégítő pontosságot nyújthat a II. és III. Kategóriájú megközelítések alátámasztásához. Abból a célból, hogy ezt megvalósítsák, a fedélzeti felszerelésnek olyannak kell lenni, mint ami a 13.6.1.2 pontban megállapított.

13.6.4.2 A II. és III. Kategóriájú eljárások hiba összetevői a következők. A III. Kategóriára az oldalirányú pontossági követelmények megegyeznek a megközelítési vonatkozási pontra meghatározott MLS megközelítési oldalszög pontosságokkal. Ezek a követelmények a következők: 6 m (20 láb) az útvonal-követési hibára (PFE) és 3,2 m (10,5 láb) a kormányzási elmozdulási zajra (CMN) (3. Fejezet 3.11.4.9.4 pont).
A II. Kategóriára az oldalirányú követelményeket úgy lehet megkapni, hogy kiszélesítik a megengedett III. Kategóriájú értékeket a megközelítési vonatkozási ponttól kifelé a II. Kategóriájú elhatározási magasságig, a 30 méterig (100 láb). Az ezeknek az értékeknek a kiszámításához használt egyenletek (méterben kifejezve) a következők:

$$PFE = 6 \times \frac{(D_{AZ-ARD} + R)}{D_{AZ-ARD}}$$

$$CMN = 3{,}2 \times \frac{\left(D_{AZ-ARD} + R\right)}{D_{AZ-ARD}}$$

$$R = \frac{DH_{CatII} - DH_{CatII}}{\tan\theta}$$

ahol:

D_{AZ-APS} = a megközelítési oldalszög adó antenna és a megközelítési alappont (küszöb) közötti távolság
R = (az elhatározási magasság) $DH_{Cat\ II}$ és $DH_{Cat\ III}$ közötti távolság
Θ = magassági szög
(*PFE* = útvonal-követési hiba; *CMN* = kormányzási elmozdulási zaj)

Egy példaként, egy 3 000 méteres futópályára és egy 3-fokos magassági szögre, a megközelítési oldalszög adó 300 méteres hátrafelé elhelyezéssel, egy III. Kategóriájú 15 méteres (50 láb) elhatározási magassággal és egy II. Kategóriájú 30 méteres (100 láb) elhatározási magassággal a következő értékeket kapják:

D_{AZ-APS} = 3 300 m
R = 286 m
$PFE_{DH\ Cat\ II}$ = 6,5 m (21,3 láb)
$CMN_{DH\ Cat\ II}$ = 3,5 m (11,5 láb)

13.6.4.3 A számított középvonalas megközelítési képesség a II. Kategóriájú elhatározási magasságig nem fogja szükségszerűen alátámasztani az automata-leszállású üzemeltetéseket, mivel az útirány-vezetést nem lehet biztosítani lefelé egészen a futópályáig és a futópálya körzetében. Azonkívül még a II./III. Kategóriára vonatkozó jóval szigorúbb hiba tűréshatárok több "visszatartást" eredményeznek az antenna telepítésében, mint az I. Kategóriánál. Elsődlegesen ez a korlátozás a megközelítési oldalszög antennának a futópálya középvonalától való oldalirányú eltolt helyzetű telepítésére vonatkozik.

13.7 Számított középvonalas megközelítések párhuzamos másodlagos futópályákra

13.7.1 A másodlagos futópálya - ahogy itt meghatározásra került - az a futópálya, amelynek eltérő a geometriai kapcsolata azzal a futópályával, amit az 'A' kiegészítő adatszó magába foglal. A számított középvonalas megközelítések a párhuzamos másodlagos futópályákra azok a megközelítések, amelyek egy olyan meghosszabbított futópálya középvonal számított repülési pályája mentén kerülnek végrehajtásra, amelyet nem egy MLS oldalszög radiállal és / vagy magassági szöggel egy egyenesbe állítottak, hanem az elsődleges futópálya középvonalával párhuzamosak.

13.7.2 Az ebben a részben lévő anyag útmutatásokat ad a számított középvonalas megközelítések megengedhető futópálya geometriáira a párhuzamos másodlagos futópályákra a 60 méteres (200 láb) elhatározási magasságig. Az ebben a részben lévő anyag az MLS és a DME / P (1.Szabvány) Szabványok és Ajánlott Gyakorlatok elméleti alkalmazásán alapszik. Az alkalmazott hiba összegzés az a konzervatív hiba összegzés, ami a 13.2 pontban megállapításra került, és ennek a hiba összegzésnek az enyhítése a 13.7.6.1 pontban került leírásra.

13.7.3 *A futópálya geometriájának szempontjai*

13.7.3.1 A G-32. számú ábra a futópálya és a berendezések geometriáját mutatja be. A másodlagos futópálya helyzete oldalirányban van megállapítva a futópálya távolságok között, méterben megadva. A negatív értékek a másodlagos futópálya elhelyezését jelentik az elsődleges futópályától balra. A másodlagos futópálya hosszirányú helyzetére mint küszöb lépcsőzésre utalunk az elsődleges futópályához vonatkoztatva. A negatív értékek a küszöb lépcsőzést jelentik az elsődleges futópálya küszöbe irányában.

13.7.4 *Nagy futópálya térköz szempontok*

13.7.4.1 További megfontolások szükségesek az olyan számított középvonalas megközelítéseknél, ahol nagy térközű párhuzamos futópályák vannak. A figyelembe veendő tényezőknek magukba kell foglalniuk:

a) a DH körzetében szükséges kielégítő jel fedésterület bizonyos párhuzamos futópálya geometriáknál szükségessé tehet egy olyan magassági szög adó antennát, amelynek a ± 40 foknál nagyobb a fedésterülete;

b) ezekre az üzemeltetésekre az MLS antennák körüli kritikus területek megnövekedhetnek; és

c) ezek az üzemeltetések szükségessé tehetik a magassági szög útirány-vezetést az elsődleges futópálya minimális siklópályája alatt.

13.7.5 *A futópálya geometriája*

13.7.5.1 A G-33. számú ábra a megengedett futópálya térközöket és a küszöb lépcsőzéseket mutatja be a másodlagos futópályára. Ez egy 3 000 méteres (10 000 láb) hosszúságú elsődleges futópálya eredményeit mutatja be. A geometria az elsődleges futópálya hosszával kismértékben változik. Az árnyékolt terület azokat az eredményeket mutatja be, amelyeket egy jelenlegi MLS és DME / P (1. Szabvány) Szabványok és Ajánlott Gyakorlatok és a 13.2 pontban megadott hibahalmaz felhasználásával kaptunk. A G-33. sz. ábra alkalmazásakor vezessék be a másodlagos futópálya térközét és küszöb lépcsőzését az ábrába. Ha a kapott pont az árnyékolt területen belül fekszik, akkor a számított középvonalas megközelítés a 60 méteres (200 láb) elhatározási magasságig /DH/ egy 3-fokos magassági szögön lehetséges.

Megjegyzés. - Az 1 200 méteres futópálya küszöb lépcsőzés közelében lévő körvonalas terület a felhasznált magassági útirány-vezetés felső határa miatt áll fenn. Erre a területre nem várható el az, hogy bármilyen üzemeltetési korlátozásnál szerepe legyen.

13.7.6 *A futópálya geometria kiterjesztése*

13.7.6.1 A repülési és földi ellenőrzések azt mutatták, hogy az árnyékolt területet a következők kiegészítőleges figyelembevételével ki lehet terjeszteni:

a) a szögbeli kiterjesztés úgy lehetséges, hogyha a meglévő magassági szög útirány-vezetés felhasználását kiterjesztik a minimális előírt oldalszög arányos útirány-vezetési szektoron kívülre. A magassági szög útirány-vezetést ennél a szögbeli kiterjesztésnél ellenőrizni kell; és
b) a radiál kiterjesztés úgy lehetséges, hogy kismértékben enyhítik a függőleges hiba összegzést 4,9 méterre (16 láb). Ez az enyhítés még így is nagyon körültekintő, és a megfelelő ILS hiba összegzés 66 százalékával [7 m (24,1 láb)] egyenlő értékű.

13.7.6.2 A G-33. számú ábra alkalmazását egy, az A-ponttal jelzett példa mutatja be. Az előbb említett kiterjesztést alkalmazva a számított középvonalas megközelítés egy másodlagos futópályára egy -1 400 méteres futópálya térközzel és +200 méteres küszöb lépcsőzéssel lehetséges.

14. A G-15. táblázat szolgáltatási szint céljainak az MLS / RNAV üzemeltetésekre való alkalmazása

14.1 Az alábbiakban tárgyalt MLS / RNAV eljárásokat a G-15. táblázatban meghatározott integritási és szolgáltatási cél folyamatossági követelményeket kielégítő földi berendezésekkel lehet lefolytatni. Ezeknek az üzemeltetéseknek a többségét csak a 2. szintű célokat kielégítő MLS földi berendezésekkel lehet végrehajtani. Az eljárások további többségénél nem szükséges a pozitív útirány-vezetés a félbeszakított megközelítés / megszakított megközelítés folyamán. Ahol az eljárási eszközök nem tudják biztosítani a szükséges akadálymentességet egy útirány-vezetés-nélküli félbeszakított megközelítés / megszakított megközelítés folyamán, ott a másodlagos útirány-vezetés valamilyen formájára lesz szükség. A másodlagos útirány-vezetési rendszer pontossági követelményét az ‘akadály-gazdagsági’ környezet természete fogja meghatározni.

14.1.1 Azoknál a ritka eseteknél, ahol az MLS / RNAV eljárás egy akadály-gazdag környezetben van, a számított akadályok általi veszélyeztetettségi idő (OET) szükségessé teheti az olyan magasszintű berendezés típusok alkalmazását, mint amilyenek a leszálláshoz szükségesek.

14.1.2 *A kritikus szakaszok meghatározása*

14.1.2.1 A következő szakkifejezések használatosak az MLS / RNAV eljárás kritikus szakasza hosszának meghatározásához:

Obstacle rich environment. Akadály-gazdag környezet. Az a környezet, ahol nem lehetséges az útirány-vezetés nélküli félbeszakított megközelítési / megszakított megközelítési eljárásnak az eljárási eszközökkel történő megszerkesztése. Másodlagos útirány-vezetésre lesz szükség a szektor minimális magasságra való emelkedés végrehajtásához.

Critical segment. Kritikus szakasz. Egy olyan szakasz, amelyen egy útirány-vezetés nélküli félbeszakított megközelítés / megszakított megközelítés a légijárművet egy akadály általi veszélyeztetésnek teszi ki.
Obstacle exposure time (OET). Akadály általi veszélyeztetettségi idő (OET). Az az időtartam, ami egy MLS / RNAV eljárás kritikus szakaszában történő repüléséhez szükséges. Ez az idő a nem-repülőgépes útirány-vezetési berendezés szükséges szolgáltatási szintjének meghatározásához használatos.

14.1.2.2 Az akadályok általi veszélyeztetettségi idő /OET/ meghatározása céljából a következő eljárást lehet követni (lásd a G-34. számú ábrát):

a) határozzák meg, hogy az útirány-vezetés-nélküli félbeszakított megközelítési / megszakított megközelítési felületnek bármely olyan lehetséges irányba való kijelölésével, amelyet az MLS / /RNAV eljárásból alkalmazni lehet, a félbeszakított megközelítés / megszakított megközelítés során van-e akadály-gazdag környezet;

b) határozzák meg, hogy eljárási eszközökkel lehetséges-e az akadályok elkerülése anélkül, hogy másodlagos útirány-vezetésre szükség lenne; és

c) határozzák meg az akadályok általi veszélyeztetettségi időt /OET/, mint azt az időtartamot, amely során az akadály az útirány-vezetés-nélküli félbeszakított megközelítési / megszakított megközelítési felületen belül van, miközben nincs eljárási lehetőség az akadály elkerültetésére.

14.2 Számított középvonalas üzemeltetések

14.2.1 Amikor az üzemeltetéseket az elsődleges futópályákra hajtják végre, akkor ezekhez az üzemeltetésekhez olyan fedélzeti berendezés szükséges, ami csak az oldalirányú útirány-vezetést számolja ki.
A függőleges útirány-vezetést a magassági funkció közvetlenül biztosítja. Az oldalirányú útirány-vezetést biztosító fedélzeti berendezésnek ugyanazon integritással kell rendelkezni, mint ami az MLS vevőnél szükséges az alap MLS üzemeltetések végrehajtásához egy egyenértékű elhatározási magasságig. Azoknál a számított középvonalas üzemeltetéseknél, amelyeket az I. Kategóriájú elhatározási magasság alatti elhatározási magasságig hajtanak végre, az szükséges, hogy a DME-nek olyan pontossága, integritása és szolgáltatási szint folyamatossága legyen, ami az üzemeltetés típusához alkalmazható.

14.2.2 Amikor az üzemeltetések egy párhuzamos másodlagos futópályára kerülnek végrehajtásra, akkor ezekhez az üzemeltetésekhez az szükséges, hogy a fedélzeti rendszer mind az oldalirányú, mind a függőleges útirány-vezetést kiszámítsa. Az elhatározási magasságokat az MLS jel fedésterületre és az elérhető számított útirány-vezetési pontosságra lehet korlátozni.

14.2.3 A 2. szintű szolgáltatási célokat kielégítő MLS földi berendezés elegendő lehet a számított középvonalas üzemeltetésekre akkor, amikor:

a) az üzemeltetés I. Kategóriájú, vagy magasabb elhatározási magasságig kerül végrehajtásra; és

b) a fedélzeti berendezés által biztosított referencia repülési pálya megszerkesztése és a számított oldalirányú és függőleges útirány-vezetés kielégíti az integritásnak az MLS vevő által az alap MLS üzemeltetésre biztosított szintjével azonos szintet.

14.2.4 Amikor a számított középvonalas üzemeltetések az I. Kategóriájú elhatározási magasság alatti magasságig kerülnek végrehajtásra, akkor az MLS földi berendezés szolgáltatási szintjének meg kell felelni az alkalmazott elhatározási magasság értéknek. Megegyezően a számított útirány-vezetést biztosító fedélzeti berendezésnek ugyanazzal az integritással kell rendelkeznie, mint ami annak az alap vevőnek lenne, ami az MLS alap üzemeltetéseket a megegyező elhatározási magasságig vezetné le.

14.3 MLS ívelt repülési pálya eljárások

14.3.1 Ezeket az eljárásokat gondosan meg kell vizsgálni ahhoz, hogy a földi berendezés szükséges szolgáltatási szintjét meghatározzák. Az MLS ívelt repülési pályájú üzemeltetésekhez az integritás és szolgáltatási folyamatosság szint legszigorúbb követelményeit az elhatározási magasságot megelőző repülési pálya szakaszra lehet alapozni. Ezekben a helyzetekben az MLS földi berendezés integritási és szolgáltatás folyamatossági céljait nem lehet kizárólag a leszállási kategóriára alapulóan kiszámítani. Azoknál az üzemeltetéseknél, ahol az akadálymentességi követelmények nagyfokú bizalmat helyeznek az útirány-vezetés pontosságára, a földi berendezés integritását és szolgáltatási céljainak folyamatosságát az "A"- Mellékletben leírt kockázati fa módszer felhasználásával lehet meghatározni. A következő körülményeket kell még számításba venni:

a) a fedélzeti berendezésnek rendelkezni kell azzal a képességgel, hogy megszerkessze a referencia repülési pályát, és kiszámítsa a függőleges és oldalirányú útirány-vezetést a fordulók során is pozitív ellenőrzést biztosítva; és

b) a fedélzeti rendszer integritásának és szolgáltatási folyamatosságának meg kell egyezni az eljárás biztonságos végrehajtásához szükséges útirány-vezetési pontosság megbízhatósági fokával.

15. Az egyszerűsített MLS konfiguráció alkalmazása

15.1 Miközben az alap és a kibővített Mikrohullámú Leszállító Rendszer konfigurációra vonatkozó Szabványok és Ajánlott Gyakorlatok egy térbeli-jel szabványt határoznak meg, addig a 3. Fejezet 3.11.3.4 pontjában meghatározott egyszerűsített MLS konfiguráció lehetővé teszi az MLS-nek a megközelítési és indulási üzemeltetések Megkívánt Navigációs Teljesítmény /RNP/ alapú alátámasztására való felhasználását (2. Fejezet 2.1.6).

15.2 A mérsékelt fedésterületi, pontossági és felügyelő rendszeri határértékek nem haladják meg azt, ami a 3. Fejezet 3.1 pontjában az ILS I. Berendezés Teljesítmény Kategóriára meghatározásra került. Így az egyszerűsített Mikrohullámú Leszállító Rendszer konfiguráció képes arra, hogy az I. Kategóriájú üzemeltetéseket az oldalszög és a magassági szög antennák méretének jelentős lecsökkentésével alátámassza. A berendezés komplexitásának további csökkentése érhető el, mivel lemondtak a kormányzási elmozdulási zaj /CMN/ követelményekről azoknál a megközelítéseket és leszállásokat kiszolgáló berendezéseknél, amelyeknél nincs szükség az automata rácsatlakozásokra.

15.3 Az egyszerűsített MLS kompatíbilis az alap és a kibővített MLS konfigurációkkal.

TÁBLÁZATOK A "G"- MELLÉKLETHEZ

G-1. táblázat: A rendszer teljesítmény összegzése

MEGJEGYZÉSEK. –

1. A veszteségek és az a ntenna nyereségek jellemző értékek.

2. A nagy adatsebesség a 3o-os oldalszög sugárnyaláb szélességnél csökkenteni fogja a szükséges adóteljesítményt 4,8 dB-el.

3. Az oldalszög adó antenna távolságát 41,7 km-nek (22,5 tengeri mérföld) véve.

4. A hátsó irányszektor antenna távolságát 23,1 km-nek (12,5 tengeri mérföld) véve.

5. A szükséges adóteljesítményt nagyobb hatékonyságú antennák alkalmazásával le lehet csökkenteni.

Megjegyzés. - Ez az érték a futópálya küszöbének keresztezési magassága, a futópálya küszöb talajszintjéhez vonatkoztatva. A futópálya küszöb magassága az MLS alapponthoz vonatkoztatottan a kiegészítő szó A2-ben kerül megadásra.

MEGJEGYZÉSEK. –

1. A bit kódolás úgy van bemutatva, hogy az alacsonyabb bit szám van a baloldalon.

2. Az adat szó címek az "A"- Függelék A-9. táblázatában vannak meghatározva, a legnagyobb helyértékű bittel az első helyen.

3. A hátsó irányszektor adatbázis nélküli berendezések a B39-ig terjedően az összes szót felhasználhatják a megközelítési oldalszög adatbázisban.

G-13. ábra: A minimális magassági felület szöge és a kapcsolódó védett fedésterületi tér hossza az MLS / RNAV megközelítési eljárásokra

A védett fedésterületi tér hossza L [m(láb)] PCH = 2,0 m	A minimális magassági felület szöge (fok), θ	
	B-727	B-747
300 (1 000)	1,81	3,49
450 (1 500)	1,23	2,36
600 (2 000)	0,95	1,79
750 (2 500)	0,77	1,44
900 (3 000)	N/A	1,21

A következő képletet lehet alkalmazni a minimális magassági felület szögének (θ) meghatározásához az oldalszög antenna fázis középpontjára vonatkozóan egy tetszés szerinti védett fedésterületi tér hosszra, "L".

$$\theta = \tan^{-1}\left[\frac{TFH + \frac{\sqrt{\lambda(L)}}{4} - PCH}{L}\right]$$

ahol:
TFH = függőleges vezérsík magasság;
PCH = az MLS antenna fázis középpontjának magassága;
λ = az MLS hullámhossza.

Megjegyzés. - A függőleges vezérsík magasság (TFH) 10,4 m-rel egyenlő a B-727-re, illetve 19,3 m-rel a B-747-re és a λ = 0,06 m. Az MLS antenna fázis középpontjának magasságát és az L távolságot méterben kell megadni akkor, ha a TFH és a λ méterben van megadva.

Az = oldalszög
El = magassági szög

MEGJEGYZÉSEK. –

1. Az adat szavak szolgáltatási folyamatossága és integritása az egyes szolgáltatási szintek szög funkciójának meghatározott értékeibe van belefoglalva.
2. A hátsó irányszektor nem szükséges az alap üzemeltetéshez.
3. Az a cél, hogy minden berendezés legalább a 2. szintű követelménynek feleljen meg.
4. Amikor DME / N használatos az MLS-el, akkor az értékeket le lehet csökkenteni $1 - 1 \times 10^{-5}$-re.
5. A 4. szintű sugárzási idők az ILS-el szerzett tapasztalatokon alapszanak, és összhangban vannak a jelenlegi üzemeltetési lehetőségekkel. Ahogy tapasztalatokat szereznek az MLS-el és azok megnövelt üzemeltetési lehetőségeket javasolnak, szükséges lehet ezeknek az értékeknek a helyesbítése.
6. Az MLS / RNAV eljárások szükségessé tehetik azt, hogy a 3. és 4. szintű integritási, szolgáltatás folyamatossági és meghibásodások közötti átlagos idő célok a magassági szögnél, a DME / P-nél és ha használatos, a hátsó irányszektornál is egyenlőek legyenek a megközelítési oldalszög adó berendezésekével.

ELŐSZÓ

Történeti áttekintés

A Légiforgalmi Távközlés Szabványait és Ajánlott Gyakorlatait a Tanács először 1949. május 30-án fogadta el, a Nemzetközi Polgári Repülési Egyezmény 37. Cikkelyében lévő előírásoknak megfelelően (Chicago, 1944.), és az Egyezmény 10. Annex-eként jelölte ki. Ezek 1950. március 1-én léptek hatályba. A Szabványok és Ajánlott Gyakorlatok a Hírközlési Szekció 1949. januárjában tartott Harmadik Ülésszaka ajánlásain alapulnak.

Egészen a Hetedik Kiadásig és azt is beleértve, az Annex 10t egy kötetben került kiadára, ami négy Részt foglalt magába, a hozzájuk kapcsolt mellékletekkel együtt: az: I. Rész "Berendezések És Rendszerek"-et, a II. Rész "Rádiófrekvenciák"-at, a, III. Rész "Eljárások"-at és a IV. Rész "Kódok és Rövidítések"-et.

A 42. Módosítással a IV. Rész törlésre került az Annex-ből; és az abban a részben elhelyezett kódok és rövidítések egy új dokumentumba, a Doc 8400-ba kerültek áthelyezésre.

A 44. Módosítás 1965. május 31-i elfogadásának eredményeként az Annex 10 Hetedik Kiadása két kötetbe került felosztásra: az I. Kötetbe (Első Kiadás), ami két részt tartalmazott: az I. Részt, a "Berendezések és Rendszerek,"-et és a II. Részt, a "Rádiófrekvenciák"-at foglalja magába, valamint a II. Kötetbe (Első Kiadás), ami a "Hírközlési Eljárások"-at tartalmazza.

A 70. Módosítás 1995. március 20-i elfogadásának eredményeként, az Amex 10 átszerkesztésre került úgy, hogy öt kötetet foglal magába: I. Kötet - Rádiónavigációs Berendezések; II. Kötet - Hírközlési Eljárások; III. Kötet - Hírközlési Rendszerek; IV. Kötet - Légtérellenőrző Radar és Összeütközés Elkerülő Rendszerek; és az V. Kötet - A Légiforgalmi Rádiófrekvencia Spektrum Felhasználása. A 70. Módosítással a III. és a IV. Kötet 1995-ben került kiadásra és az V. Kötet kiadása a 71.Módosítással volt tervezve.

A II. Kötet olyan anyagot tartalmaz, amelynek a jogi helyzete a Léginavigációs Szolgálatok Eljárásai (PANS) volt. Ezt az utóbbi anyagot a II. Kötet Első Kiadása előtt a PANS - Rádiótávbeszélő Eljárások (Doc 7181) foglalta magába, és ez a dokumentum most hatálytalanításra került.

Az "A" táblázat mutatja be az Annex 10 eredetét és a 43. Módosítást követő módosítások származását, a bennük lévő legfontosabb témák összefoglalásával együtt, ahol megfelelő, és azokat az időpontokat, amikor a Tanács a z Annex-et és a módosításokat elfogadta, illetve amikor azok hatályba léptek, és végül amikor alkalmazhatóakká váltak.

A Szerződő Államok tevékenysége

Az eltérések bejelentése. A Szerződő Államok figyelmét felhívják az Egyezmény 38. Cikkelye értelméből eredő azon kötelezettségükre, amely szerint a Szerződő Államokat felkérik arra, hogy jelentsenek be a Szervezetnek minden olyan eltérését és gyakorlatot, mely a nemzeti szabályaik és eljárásaik, valamint az ebben az Annex-ben lévő és ezt követően módosított Nemzetközi Szabványok között fennáll. Kérik a Szerződő Államokat, hogy azt a bejelentést terjesszék ki az ezen Annex-ben lévő Ajánlott Gyakorlatoktól való eltérésekre is, amennyiben az ilyen eltérés lényeges jelentőséggel bír a léginavigáció biztonsága szempontjából. Továbbá felkérik a Szerződő Államokat, hogy folyamatosan tájékoztassák a Szervezetet minden olyan eltérésről, mely ezt követően felmerül, vagy amennyiben bármely korábban bejelentett eltérés megszűnik. Egy, az eltérések bejelentésére vonatkozó külön felkérés kerül megkküldésre a Szerződő Államok részére azonnal ezen Annex egyes módosításainak elfogadását követően .

Felhívják továbbá az Államok figyelmét az Annex 15 azon előírásaira, amelyek szerint a nemzeti szabályaik és gyakorlataik, valamint az ICAO Szabványok és Ajánlott Gyakorlatok között felmerülő eltéréseket a Légiforgalmi Tájékoztató Szolgálaton keresztül tegyék közzé, az Egyezmény 38. cikkelyében lefektetett, az Államokra vonatkozó kötelezettségen felül.

A tájékoztatás közzététele. Az Annex 10-ben meghatározott Szabványoknak, Ajánlott Gyakorlatoknak és Eljárásoknak megfelelően biztosított, a légijármű üzemeltetéseket érintő berendezések, szolgálatok és eljárások változásait, azok életbeléptetését és megszüntetését be kell jelenteni, és az Annex 15 előírásainak megfelelően kell érvénybe helyezni.

Az Annex szövegének használata a nemzeti szabályozatokban. A Tanács 1948. április 13-án elfogadott egy határozatot, amelyben felhívja a Szerződő Államok figyelmét annak kívánatosságára, hogy saját nemzeti szabályaikban - amennyire csak lehetséges - használják azoknak az ICAO Szabványoknak a pontos kifejezésmódját, amelyek szabályás jellegűek, ugyanígy a Szabványoktól való eltéréseke jelölésére is, beleértve minden olyan kiegészítő nemzeti szabályzatot is, amely a léginavigáció biztonsága vagy szabályossága szempontjából fontos. Ahol csak lehetséges, ennek az Annex-nek a szövege szándékosan olyan módon került leírásra, hogy nagyobb szövegbeli változtatás nélkül be lehessen foglalni a nemzeti törvényalkotásba.

Az Annex 10 II. Kötetébe foglalt Légiforgalmi Szolgálatok Eljárásai nem képviseli azt a jogi helyzetet, mint amit a Tanács által az Egyezményhez csatolt Annex-ek Szabványai nyújtanak, és ennek megfelelően nem esik azon kötelezettség alá, amit az Egyezmény 38. Cikkelye szerinti ráruházna, azaz, hogy a "nem-alkalmazás" esetét jelentő eltérést közzé kell tenni. Azonban felhívják az Államok figyelmét a vonatkozó, az Annex 15-ben leírt előírásokira, hogy az Államok a Légiforgalmi Tájékoztató Kiadványukban vegyék jegyzékbe a saját eljárásaik és a vonatkozó ICAO eljárások közötti jlényeges különbségeket.

Az Annex alkotó-részeinek jogi helyzete

Egy Annex az alábbi alkotó-részekből épül fel, azonban nem feltétlenül található meg ezek mindegyike, de szükségszerűen megtalálhatók minden egyes Annex-ben; ezek az alábbi jogi helyzetet foglalják el:

1. – Az Annex-et alkotó anyagok a tulajdonképpeni:

a) *Szabványok és Ajánlott Gyakorlatok,* amelyeket a Tanács fogadott el az Egyezmény előírásainak megfelelően. Meghatározásuk a következő:

Szabvány: Minden olyan - a fizikai jellemzőkre, összetételre, anyagra, teljesítőképességre, személyzetre vagy eljárásra vonatkozó - meghatározás, amelynek egységes alkalmazását a nemzetközi léginavigáció biztonsága szempontjából szükségesnek tekintenek, és amelynek a Szerződő Államok az Egyezmény értelmében eleget kell, hogy tegyenek; a teljesítés lehetetlensége esetén annak bejelentése a Tanács részére a 38. Cikkely alapján kötelező.

Ajánlott Gyakorlat: Fizikai jellemzőkre, összetételre, anyagra, teljesítőképességre, személyzetre vagy eljárásra vonatkozó minden olyan meghatározás, amelynek egységes alkalmazását kívánatosnak tekintik a nemzetközi léginavigáció biztonsága, szabályszerűsége vagy hatékonysága érdekében, és amelynek teljesítésére a Szerződő Államoknak az Egyezmény értelmében törekedniök kell

b) *Függelékek:* a kényelmi szempontból különállóan csoportosított anyagok, de ezek részét képezik a Tanács által elfogadott Szabványoknak és Ajánlott Gyakorlatoknak.

c) *Meghatározás:* a Szabványokban és Ajánlott Gyakorlatokban használt azon szakkifejezések értelmezése, amelyek nem maguktól értetődőek, amennyiben azok nem rendelkeznek elfogadott szótári jelentéssel. Egy meghatározásnak nincs független jogi helyzete, de minden egyes Szabványnak és Ajánlott Gyakorlatinak, amelyben használják, elengedhetetlen részei, mivel a szakkifejezés jelentésének értelmi változása befolyásolná az előírás értelmét.

d) A *Táblázatok* és *ábrák* azok, amelyek kiegészítik vagy illusztrálják azokat a Szabványokat és Ajánlott Gyakorlatokat, amelyekre azokban utalnak; ezek a vonatkozó Szabványoknak és Ajánlott Gyakorlatoknak részét képezik, és ugyanazzal a jogi helyzettel rendelkeznek.

2. – A Tanács által a Szabványokhoz és Ajánlott Gyakorlatokhoz kapcsolódóan közzétételre elfogadott anyagok:

a) *Előszavak,* a Tanács tevékenységén alapuló történeti és magyarázó anyagokat tartalmazzák, és magukba foglalják az Államoknak - a Szabványoknak és Ajánlott Gyakorlatoknak és az Ajánlott Eljárásoknak - az Egyezményből és az Elfogadási Határozatból következő kötelezettségeinek magyarázatát is.

b) A *Bevezetések*, melyek magyarázó anyagot tartalmaznak az Annex részeinek, fejezeteinek vagy szakaszainak elején, hogy segítsenek a szöveg alkalmazásának megértésében;

c) A *Megjegyzések* a szövegbe foglalva, értelemszerűen, hogy a kérdéses Szabvánnyal vagy Gyakorlati Ajánlással kapcsolatban tényszerű tájékoztatást vagy támpontot adjanak, ezek azonban nem képezik a Szabványok vagy Gyakorlati Ajánlások részét;

d) *Mellékletek*, melyek a Szabványokat és Gyakorlati Eljárásokat kiegészítő anyagot tartalmaznak, vagy azok alkalmazásához nyújtanak útmutatást.

Felelősség elhárítás szabadalmakra vonatkozóan

Felhívjuk a figyelmet annak a lehetőségre, hogy az ebben az Annex-ben lévő Szabványok és Ajánlott Gyakorlatok bizonyos elemei lehet, hogy szabadalom vagy egyéb szellemi tulajdoni jog tárgyát képezik. Az ICAO nem vállal felelősséget vagy kötelezettséget azért, hogy nem azonosította az ilyen jogok valamelyikét vagy mindegyikét. Az ICAO nem foglal állást semmilyrn "igényelt" találmány vagy egyéb szellemi tulajdoni jog fennállására, érvényességére, tárgyára vagy alkalmazhatóságára vonatkozóan, és azt "vállalja", hogy nincs felelősségeés kötelezettsége ennek megfelelően és erre vonatkozóan.

A nyelv kiválasztása

Ez az Annext négy nyelven került elfogadásra - angolul, franciául, oroszul és spanyolul. Minden egyesi Szerződő Államot felkérnek, hogy ezeknek a különféle nyelvű szövegeknek az egyikét válasszák ki nemzeti felhasználásra, valamint az Egyezményben meghatározott egyéb célokból, akár a közvetlen felhasználás, akár a saját nemzeti nyelvre történő fordítás útján, és ennek megfelelően értesítsék a Szervezetet.

Szerkesztési gyakorlat

A következő gyakorlat kerül következetes alkalmazásra abból a célból, hogy az egyes állítások jogi helyzete egyetlen pillantással megállapítható legyen: a *Szabványok* vékony antikva betű típussal vannak nyomtatva; az *Ajánlott Gyakorlatok* vékony dőlt betűvel vannak szedtve, jogi helyzetüket az **Ajánlás** szó jelzi; a *Megjegyzések* vékony dőlt betűvel vannak szedve, jogi helyzetüket a *Megjegyzés* szó jelzi.

A következő szerkesztési gyakorlatot követtük az előírások megfogalmazásánál: a Szabványok esetében a "kell", az Ajánlott Gyakorlatok esetében pedig a "kellene" felszólító igét használtuk.

Az ebben a dokumentumban alkalmazott mértékegységek megegyeznek a Nemzetközi Mértékegység Rendszerrel (SI) úgy, ahogy az a Nemzetközi Polgári Repülési Egyezmény 5. Annex-ében meghatároztásra került. Ott, ahol az Annex 5 megengedi a nem-SI mértékegységek alternatív használatát, azok zárójelben feltűntetve követik az alap mértékegységetl. Ahol a két rendszer szerinti mértékegységek szerepelnek, nem szabad feltételezni azt, hogy az értékek egyenlők és felcserélhetők. Azt azonban el lehet fogadni, hogy a biztonság azonos szintjét lehet elérni, ha bármelyik mértékegyég rendszert önállóan alkalmazzák.

Ennek a dokumentumnak egy részére való bármely utalás, amely egy számmal és/vagy címmel van azonosítva, annak a résznek az összes al-részét is magába foglalja.

Az Annex 10. II. kötet anyagának betűtformájára vonatkozóan, a Léginavigációsi Szolgálatok Eljárásai vékony dőlt betűkkel vannak szedve, és a jogi helyzetüket a **PANS** előtag jelzi.

"A" táblázat: Az Annex 10 - II. Kötetének módosításai

Módosítás	Forrás(ok)	Tárgya(k)	Elfogadás - Hatálybalépés - Bevezetés dátuma
44	A Hírközlési /COM/ Szekció Hetedik ülése	A II. kötet létrehozása azoknak az eljárásoknak a beépítése, amelyeket korábban a Doc 7181 - *PANS* - *"Rádiótávbeszélő Eljárás*ok" foglaltak magukba, szükségessé vált a khírközlési eljárásokra vonatkozó előírások általános átrendezése, és ez az új II. kötetben meg is történt.	1965. május 31 1965. október 1 1966. március 10
45	A Távgépíró Szakértők szak- csoportjának Hatodik. ülése; Negyedik Léginavigációs /AN/ konferencia	A Légiforgalmi Állandóhelyű Távközlési Szolgálat /AFTN/ eljárásainak több részletes megváltoztatása; az 5. és 6. fejezet módosítása, azoknak az eljárásoknak a jóval pontosabb közlése, amelyek a légijármű vezetője és a légiforgalmi irányító közötti közvetlen összeköttetése során történik, és a 3.7 pont - "A Rövidítések és kódok" átfogalmazása, egy, a 42. Módosítás által bevezetett nem szándékos jelentés helyesbítése.	1966. december 12 1967. április 12 1967. augusztus 24
46	A Légiforgalmi Irányítás /ATC/ Automatizálási Szakcsoport Ötödik ülése	A Légiforgalmi Irányítás /ATC/ számítógépében való fel- használásra tervezett Légiforgalmi Szolgálati /ATS/ közlemények továbbításának eljárásai.	1967. június 7 1967. október 5 1968. február 8
47	A Hírközlési / Üzemeltetési /COM/OPS/ Szekció ülése	Új, egyszerűsített Légiforgalmi Mozgó-szolgálati Vészhelyzeti Eljárások bevezetése, amelyek alkalmasabbak a nemzetközi polgári légiközlekedés speciális követelményeihez.	1967. december 11 1968. április 11 1968. augusztus 22
48	A Távgépíró Szakértők Szak- csoportjának Hetedik. ülése	Változtatások bevezetése a közlemények osztályozásában és a telex-eljárásokban, az AFTN automatikus üzemelésében szerzett tapasztalatok fényében.	1969. január 23 1969. május 23 1969. szeptember 18

49	Az Automatizált Adatcsere Rendszerek Szakcsoportjának Első ülése; Hatodik Léginavigációs /AN/ konferencia	Előírás a 7-bites kód használatára adattovábbításra közepes jelátviteli sebességnél; a légiforgalmi mozgó szolgálat közleményeinek kategóriáira vonatkozó előírások bevezetése. A Regionális Kiegészítő Eljárások állandósításának és beterjesztésének tanulmányozása alapján, ez a következő témákra vonatkozó eljárásokat vonja maga után: Megfelelő kikerülő útvonal-listák az AFTN hírközlési összeköttetési központokban; a GG vagy magasabb prioritás jelzéssel ellátott AFTN közlemények korai feladása; a 121,5 MHz frekvencia figyelése hosszú-távú víz fölötti repülések során; a légijármű által leadott légijelentést, vagy meteorológiai tájékoztatást tartalmazó	1970. június 1 1970. október 1 1971. február 4
50	Az 5. Észak-Atlanti Körzeti Légi- navigációs /NAT RAN/ ülés; az Automatizált Adatcsere Rendsze- rek Szakcsoport Második ülése; Léginavigációs tanulmány a Körzeti Léginavigációs /RAN/ ülés ajánlásainak világméretű alkalmazhatóságáról; Hatodik Léginavigációs /AN/ konferencia	A "Hertz (Hz)" szó bevezetése a "ciklus per szekundum (c/s)" helyett, mint a frekvencia elektromos és rádiótechnikai mértékegysége; változások az AFTN forgalmazás naplóinak rövid- és hosszú-távú megőrzéséről és a hírközlési összeköttetési naplók 30 napos megőrzéséről szóló előírásokban; a II. Kötet Bevezetésének kibővítése a 7-bites kódolt karakterkészletről szóló anyaggal; az "ATS közvetlen beszéd-üzemű kör", a "Meteorológiai operatív csatorna" és a "Meteorológiai operatív távközlési hálózat" meghatározások bevezetése; a 3. és 4. Fejezetek előírásainak újraszervezése, azzal, hogy a 3. Fejezetbe csoportosították a nemzetközi légiforgalmi távközlési szolgálat négy részére vonatkozó általános előírásokat, a 4. Fejezetbe pedig a légi- forgalmi állandóhelyű szolgálatra vonatkozó előírásokat; az AIREP formátumú légi-jelentések rögzítésére vonatkozó előírások.	1972. március 24 1972. július 24 1972. december 7
51.	Hatodik EUM Körzeti Légi- navigációs ülés	Az AFTN közlemények előre meghatározott szétosztásának rendszerére vonatkozó előírások bevezetése.	1972. december 11 1973. április 11 1973. augusztus 16

1 A módosítás csak az I. Kötetet érintette.

2 Nem érint semmilyen Szabványt vagy Ajánlott Gyakorlatot.

3 Csak a III. és V. Kötetet érintette.

4 Nem érinti a II. Kötetet.

Bevezetés

A nemzetközi légiforgalmi távközlési szolgálat célja a nemzetközi léginavigáció biztonságához, rendszerességéhez és hatékonyságához szükséges távközlési hálózat és rádióberendezések biztosítása.

Ebben a kiadványban rögzítjük a nemzetközi Légiforgalmi Távközlési Szolgálat eljárásait, világméretű használatra. Elismerjük, hogy bizonyos esetekben szükség lehet Kiegészítő Eljárásokra annak érdekében, hogy megfeleljenek az ICAO Körzetek konkrét követelményeinek. Bármely ilyen célra javasolt Kiegészítő Eljárásnak, a körzetre specifikus követelménynek kell lennie, és nem lehet olyan előírás, amely bele van foglalva a világméretű ICAO Eljárásokba, vagy azokkal ellentmondásban van.

Ebben a dokumentumban helyt adtunk az ITU Rádiószabályzat bizonyos elemeinek, ahol ez helyénvaló. Felhívjuk ezen Eljárások felhasználóinak figyelmét arra, hogy a Nemzetközi Távközlési Egyezmény Rádiószabályzat függeléke átfogó természetű, ezért minden ide tartozó esetben alkalmazni kell.

A "Rádiószabályzat"-ra történő minden hivatkozás a Nemzetközi Távközlési Unió (ITU) által kiadott Rádiószabályzatra értendő.

A kommunikációs eljárásokat a DOC 8400-ban található Rövidítésekkel és Kódokkal, valamint azokkal az
egyéb kódokkal és rövidítésekkel együtt kell alkalmazni, amelyeket az ICAO a távközlésben történő használatra jóváhagy.

A II. Kötet számos olyan, tájékoztatások cseréjére vonatkozó eljárást tartalmaz, amelyet elsősorban a kis modulációs sebességű távközlésre dolgoztak ki, ahol a 2-es és 3-as számú Nemzetközi ABC kódolt karakterei használatosak. A közepes és nagy jelátviteli sebességnél használt 5-ös számú Nemzetközi ABC-re (IA-5) vonatkozó előírások a 10-es Annex III. kötetében találhatók.

1. FEJEZET: MEGHATÁROZÁSOK

Amikor az ebben a kiadványban lévő kifejezéseket használjuk, akkor a jelentésük az ebben a fejezetben meghatározott jelentésben.

1.Megjegyzés: További speciális távközlési szakkifejezések és jelentéseik az "A" melléklet jegyzékében kerültek felsorolásra..

2.Megjegyzés: A "Rádiószabályzat"-ra történő minden hivatkozás a Nemzetközi Távközlési Unió (ITU) által kiadott Rádió- szabályzatra értendő. A "Rádiószabályzat"-ot rendszeresen kiegészítik azokkal a határozatokkal, melyek a rendesen 2 – 3 évenként megtartott World Radiocommunication Conference *(Rádiókommunikációs Világ Tanácskozás)* Záróokmányában *jelennek meg. Az ITU folyamatban lévő ügyeiről - mivel azok kihatással vannak a légiközlekedésben használt rádióberendezések frekvencia használatára - a* "Radio Frequency Spectrum Requirements for Civil Aviation" *(Polgári Légiforgalmi Rádiófrekvencia-tartomány Követelményeinek Kézikönyve) tartalmaz további információkat, beleértve az ICAO jóváhagyott hivatalos célkitűzéseiről, álláspontjáról szóló hivatalos kiadványt is (Doc 9718).*

1.1 Szolgálatok

Aeronautical broadcasting service - *Légiforgalmi rádióadó szolgálat*.
A léginavigácóval kapcsolatos tájékoztatások adására létesített rádióadó szolgálat.

Aeronautical fixed service (AFS) - *Légiforgalmi állandóhelyű szolgálat.*
Távközlési szolgálat meghatározott állandóhelyű pontok között, amelyet elsősorban a léginavigáció biztonsága és a légiforgalmi szolgálatok rendszeres, hatékony és gazdaságos üzemelése céljából nyújtanak.

Aeronautical fixed telecommunication network (AFTN) - *Légiforgalmi állandóhelyű távközlési hálózat*. Légiforgalmi állandóhelyű áramkörök világméretű rendszere, amely a légiforgalmi állandóhelyű szolgálat részét képezi, és amelyet az azonos vagy kompatibilis kommunikációs jellemzőkkel rendelkező légiforgalmi állandóhelyű állomások közötti közlemény- és/vagy digitális adatcsere céljából hoztak létre.

Aeronautical mobile service (RR S1.32) - *Légiforgalmi mozgó szolgálat (RR S1.32)*. Mozgó szolgálat légiforgalmi állomások és légijármű-állomások között, vagy légijármű-állomások között, amelyben mentőtutaj-állomások is részt vehetnek; a kényszerhelyzeti helymeghatározó rádió-irányjeladó állomások szintén részt vehetnek ebben a szolgálatban a kijelölt vész- és kényszerhelyzeti frekvenciákon.

Aeronautical mobile (R)* R - Route = Útvonal
* ***service (RR S1.33)*** - *Légiforgalmi mozgó "R"* szolgálat (RR S1.33)*. Olyan légiforgalmi mozgó szolgálat, amelyet a repülések biztonságával és rendszerességével kapcsolatos rádiólevelezés céljára tartanak fenn, elsősorban az nemzeti és nemzetközi polgári légiútvonalakon.

Aeronautical mobile-satellite service (RR S1.35)- *Légiforgalmi mozgó-műholdas szolgálat (RR S1.35)*
Olyan mozgó-műholdas szolgálat, amelyben a mozgó földi állomások, légijárművek fedélzetén találhatók. A mentőtutaj-állomások és a kényszerhelyzeti helymeghatározó rádió-helyjeladó állomások szintén részt vehetnek ebben a szolgálatban.

Aeronautical mobile-satellite (R)* R - Route = Útvonal
* ***service (RR S1.36)***- *Légiforgalmi mozgó-műholdas "R"* szolgálat (RR S1.36)*. Olyan légiforgalmi mozgó-műholdas szolgálat, amelyet a repülések biztonságával és rendszerességével kapcsolatos rádiólevelezésre tartanak fenn, elsősorban a nemzeti és nemzetközi lpolgári égiútvonalakon.

Aeronautical radio navigation service (RR S1.46) - *Légiforgalmi rádiónavigációs szolgálat (RR S1.46)*. A légijárműveken történő felhasználásra, azok hatékony és biztonságos üzemelése érdekében nyújtott rádiónavigációs szolgálat.

Megjegyzés. - Referenciaképpen, valamint a légiforgalmi rádiónavigációs szolgálat fenti meghatározásának jobb megértése végett hivatkozunk az alábbi Rádiószabályzatokra:
RR S1.10 Rádiónavigáció: *Navigáció céljára használt rádió-helymeghatározás, beleértve az akadályokra történő figyelmeztetést is.*

RR S1.9 Rádió-helymeghatározás : *Egy tárgy helyzetének, sebességének és/vagy egyéb jellemzőinek meg- határozása, vagy ezekre a paraméterekre vonatkozó információ megszerzése, a rádióhullámok terjedési tulajdonságainak felhasználásával.*
Aeronautical telecommunication service - *Légiforgalmi távközlési szolgálat.* Bármely légiforgalmi céllal nyújtott távközlési szolgálat.

International telecommunication service - *Nemzetközi távközlési szolgálat.* Távközlési szolgálat különböző Államok hivatalai vagy állomásai között, vagy olyan mozgó állomások között, amelyek különböző Államokhoz tartoznak, vagy különböző Államokban vannak**.**

1.2 Állomások

Aerodrome control radio station - *Repülőtéri légiforgalmi irányítás rádióállomása*. A repülőtéri irányítótorony és a légijárművek, vagy mozgó légiforgalmi állomások közötti rádiólevelezést biztosító állomás.

Aeronautical fixed station - *Légiforgalmi állandóhelyű állomás.*
A légiforgalmi állandóhelyű szolgálat állomása.

Aeronautical station (RR S1.81)- *Légiforgalmi állomás (RR S1.81).*
A légiforgalmi mozgó szolgálat földi állomása. Bizonyos esetekben a légiforgalmi állomás lehet például hajó fedélzetén, vagy tengeri bója fedélzetén is.

Aeronautical telecommunication station - *Légiforgalmi távközlési állomás*.
A légiforgalmi távközlési szolgálat állomása.

AFTN communication centre - *AFTN kommunikációs (távközlési) központ*.
Olyan AFTN állomás, amelynek elsődleges feladata a hozzá kapcsolt további AFTN állomásoktól (vagy állomásoknak) az AFTN forgalmazás átjátszása (közvetítése), vagy ismételt feladása.

AFTN destination station - *AFTN célállomás*.
Az az AFTN állomás, amelynek a közleményt és/vagy digitális adatokat megküldték, feldolgozásra, illetve a címzettnek történő kézbesítésre.

AFTN origin station - *AFTN feladó állomás*.
Az az AFTN állomás, amely a közleményt és/vagy digitális adatokat elfogadta ahhoz, hogy az AFTN hálózaton keresztül továbbítsa.

AFTN station - *AFTN állomás.*
Olyan állomás, amely a légiforgalmi állandóhelyű távközlési hálózat (AFTN) részét képezi és akként is üzemel, egy Állam fennhatósága vagy el1enőrzése alatt.

Air-ground control radio station - *Levegő-föld irányítási rádióállomás*.
Olyan légiforgalmi távközlési állomás, amelynek elsődleges feladata egy adott területen belül a légijárművek üzemeltetésével és irányításával kapcsolatos kommunikáció kezelése.

Aircraft station (RR S1.83) - *Légijármű-állomás (RR S1.83)*
A légiforgalmi mozgó szolgálat mozgó állomása, amely nem mentőtutaj-állomás, és amely légijármű fedélzetén van elhelyezve.

Communication centre - *Kommunikációs központ*.
Légiforgalmi állandóhelyű állomás, amely a hozzá közvetlenül kapcsolódó több más légiforgalmi állandóhelyű állomástól (vagy állomásnak) a távközlési forgalmazás átjátszását (közvetítését), vagy ismételt feladását végzi.

Mobile surface station - *Mozgó földi állomás*.
A légiforgalmi távközlési szolgálatban résztvevő állomás, amely nem légijármű-állomás, és amelyet mozgás közbeni, vagy előre nem meghatározott pontokon történő megállás közbeni használatra szánnak.

Network station - *Hálózati állomás*.
Rádiótávbeszélő hálózat részét képező légiforgalmi állomás.

Radio direction finding (RR S1.12) - *Rádió-iránymérés (RR S1.12)*.
Rádió helymeghatározás, amelynek során rádióhullámok vételét használják fel egy állomás, vagy objektum irányának meghatározására.

Radio direction-finding station (RR S1.91) - *Rádió iránymérő állomás (RR S1.91)* Rádió-iránymérést végző rádió helymeghatározó állomás.

Megjegyzés: A rádió-iránymérés légiforgalmi alkalmazása a légiforgalmi navigációs szolgálat körébe tartozik.

Regular station - *Illetékes állomás*.
Az az állomás, amelyet rendes körülmények között az útvonal levegő-föld rádiótávbeszélő hálózatát alkotó állomások közül kiválasztottak arra, hogy a légijárművekkel összeköttetést tartson vagy azok adását vegye.

Tributary station - *Alárendelt állomás*.
Egy légiforgalmi állandóhelyű állomás, amely kaphat és küldhet közleményeket és/vagy digitális adatokat, de amely nem végez átjátszást, kivéve hasonló állomások kiszolgálása céljából, amelyek rajta keresztül lettek egy kommunikációs központhoz kapcsolva.

1.3 Összeköttetési módszerek

Air-ground communication - *Levegő-föld összeköttetés*.
Kétirányú összeköttetés a légijárművek és a föld felszínén található állomások, vagy helyszínek között.

Air-to-ground communication - *Levegő-föld irányú összeköttetés..*
Egyirányú összeköttetés a légijárművektől a föld felszínén található állomások vagy helyszínek felé.

Blind transmission - *Vak-adás*.
Egy állomás adása egy másik állomásnak olyan körülmények között, amikor kétirányú összekötetést nem sikerült létrehozni, de feltételezik, hogy a hívott állomás képes venni az adást.

Broadcast - *Általános adás*.
A léginavigációval kapcsolatos tájékoztatások adása, amelyet nem egy konkrét állomásnak vagy állomásoknak címeznek.

Duplex - *Duplex*.
Olyan összeköttetés, amelyen keresztül két állomás között egyidejűleg mindkét irányban folyhat távközlés.

Ground-to-air communication **-** *Föld-levegő irányú összeköttetés.*
Egyirányú összeköttetés a föld felszínén található állomásoktól vagy helyszínektől a légijárművek felé.

Interpilot air-to-air communication **-** *Légijárművezetők közötti levegő-levegő összeköttetés.*
Kétirányú összeköttetés egy kijelölt levegő-levegő csatornán, mely lehetővé teszi a távoli, vagy óceáni területek fölött repülést végző, a VHF földi állomások hatótávolságán kívül eső légijárművek számára, hogy egymás közt kicserélhessék a szükséges üzemeltetési információkat és elősegítsék az üzemeltetési problémák megoldását.

Non-network communication **-** *Hálózaton kívüli összeköttetés.*
Rádiótávbeszélő összeköttetés, melyet a légiforgalmi mozgó szolgálat egy állomása hajt végre, de amelyet nem egy rádiótávbeszélő hálózat részeként hajtanak végre.

Radiotelephony network - *Ráditávbeszélő hálózat*
Légiforgalmi rádiótávbeszélő állomások egy csoportja, amelyek ugyanazon csoportba tartozó rádiófrekvenciákon üzemelnek és figyelnek, és amelyek egy meghatározott módon segítik egymást abban, hogy biztosítsák a levegő-föld összeköttetés maximális megbízhatóságát és a levegő-föld forgalmazás elosztását.

Readback **-** *Visszaolvasás*
Egy eljárás, amely szerint a vevő állomás visszaismétli a vett közleményt, vagy annak egy megfelelő részét az adó állomásnak, abból a célból, hogy megerősítést nyerjen a közlemény pontos vételéről.

Simplex **-** *Szimplex*
Egy módszer, melyben két állomás között egyszerre csak egy irányban folyhat távközlés.

Telecommunication (RR S1.3) **–** *Távközlés (RR S1.3)*
Bármilyen jellegű jelek, jelzések, írások, képek és hangok, vagy bármiféle tartalom (átvitt jelé) továbbítása, kisugárzása, vagy vétele vezetéken keresztül, rádióhullámok útján, optikai módon, vagy egyéb elektromágneses rendszerek segítségével.

1.4 Iránymérés

Homing **-** *Iránykeresés, célra repülés*
Eljárás, melyben egy rádióállomás iránymérő berendezését használják egy másik rádióállomás adásának felhasználásával, ahol legalább az egyik állomás mozgó állomás, és ahol a mozgó állomás folyamatosan halad a másik állomás felé.

Radio bearing - *Rádió-irányszög*.
Egy meghatározott elektromágneses hullámforrás látszólagos iránya és egy vonatkoztatási irány közötti szög, ahogy azt egy rádió-iránymérő állomás meghatározta. Földrajzi rádió-irányszögről (true radio bearing) beszélünk akkor, ha a vonatkoztatási irány a földrajzi Észak. Mágneses rádió-irányszögről (magnetic radio bearing) beszélünk akkor, ha a vonatkoztatási irány a mágneses Észak.

1.5 Távgépíró rendszerek

Automatic relay installation - *Automatikus átjátszó állomás*.
Olyan távgépíró berendezés (állomás), ahol automatikus berendezést alkalmaznak a közlemények átvitelére a bejövő és a kimenő vonalak között.

Megjegyzés: Ez a megnevezés magába foglalja a teljesen automatikus és a fél-automatikus állomásokat is.

Fully automatic relay installation - *Teljesen automatikus átjátszó állomás.*
Olyan távgépíró berendezés (állomás), ahol egy bejövő közlemény közvetítési feladatainak értelmezése és az ebből következően szükséges kapcsolatok létrehozása - a közlemény újra-feladása céljából -, valamint minden egyéb rendes átjátszási tevékenység automatikusan történik, ezért kezelői beavatkozásra - a felügyeletet kivéve - nincs szükség.

Message field - *Közleménymező.*
Egy közlemény valamely kijelölt része, amely meghatározott adatelemeket tartalmaz.

Semi-automatic relay installation - *Félautomata átjátszó állomás.*
Olyan távgépíró állomás, ahol egy bejövő közlemény közvetítési feladatainak értelmezéséhez és az ebből következően szükséges kapcsolatok létrehozásához - a közlemény iújra-feladása céljából - kezelő személy beavatkozása szükséges, de ahol az átjátszással kapcsolatos minden egyéb rendes tevékenység automatikusan történik.

Teletypewriter tape - *Távgépíró szalag.*
Az a szalag, amelyen a jeleket az ötegységes Start-Stop kód segítségével, teljesen elválasztott perforációval (Chad Type) vagy részlegesen elválasztott perforációval (Chadless Type) rögzítik, távgépíró vonalakon történő továbbítás céljából.

"Torn-tape" relay installation - K*ézi ("tépett szalagos") átjátszó állomás.*
Olyan telex állomás, amelyben a közleményeket telex szalag formájában veszik és játsszák át, és ahol az átjátszással kapcsolatos minden tevékenységhez a kezelő beavatkozása szükséges.

1.6 Ügynökségek

Aeronautical telecommunication agency - *Légiforgalmi távközlési ügynökség.*
Egy ügynökség, amely a légiforgalmi távközlési szolgálat egy vagy több állomásának üzemeltetéséért felelős.

Aircraft operating agency - *Légijármű-üzemeltető ügynökség (járató).*
Az a személy, szervezet vagy vállalkozás, amely egy légijármű üzemeltetésével foglalkozik, vagy arra ajánlkozik.

1.7 Frekvenciák

Primary frequency - *Elsődleges frekvencia*.
Az a kijelölt rádiótávbeszélő frekvencia, amelyet egy légijármű elsődlegesen használhat a levegő-föld kommunikációra egy rádiótávbeszélő hálózatban.

Secondary frequency - *Másodlagos frekvencia*.
Az a kijelölt rádiótávbeszélő frekvencia, amely levegő-föld kommunikáció céljából egy légijármű részére tartalékként áll rendelkezésre egy rádiótávbeszélő hálózatban.

1.8 Adatkapcsolati összeköttetések

Controller-pilot data link communications (CPDLC) – *Légiforgalmi Irányító és Légijárművezető Közötti Digitálisi Adatcsere (CPDLC)*
A légiforgalmi irányító és a légijárművezető közötti távközlési módszer, ahol az ATC közleményeket adatátviteli összeköttetés segítségével továbbítják..

Current data authority – *Az Adatkapcsolatot Jelenleg Biztosító Egység*

Egy olyan kijelölt földi rendszer, melyen keresztül a Légiforgalmi irányítás – légijárművezető közötti adatkapcsolati összeköttetési (CPDLC) párbeszéd létrehozása megengedett a pilótakabin és az adott légijármű irányításáért pillanatnyilag felelős légiforgalmi irányító között.

Downstream data authority *– A Soronkövetkező Adatkapcsolatot Biztosító Egység*
Egy, a jelenlegi adatkapcsolati egységtől különböző, kijelölt földi rendszer, amelyen keresztül a légijárművezető összeköttetésbe léphet egy illetékes ATC (Légiforgami Irányító) egységgel, abból a célból, hogy egy későbbi engedélyt beszerezhessen.

Next data authority *– Az Adatkapcsolatot Legközelebb Biztosító Egység*
Az a földi rendszer, amelyet az *Adatkapcsolatot Jelenleg Biztosító Egység* jelöl ki, abból a célból, hogy a későbbi összeköttetés és irányítás átadás megtörténhessen.

1.9 Vegyes meghatározások

Aeronautical fixed circuit - *Légiforgalmi állandóhelyű távközlési áramkör.*
A légiforgalmi állandóhelyű szolgálat (AFS) részét képező áramkör.

Aeronautical fixed telecommunication network circuit - *Légiforgalmi állandóhelyű távközlési hálózati (AFTN)* vonal.
A légiforgalmi állandóhelyű távközlési hálózat (AFTN) részét alkotó vonal.

Aeronautical teleocommunication log - *Légiforgalmi távközlési napló*.
Egy légiforgalmi távközlési állomás tevékenységéről készült feljegyzések.

Air-report - *Légi jelentés (AIREP jelentés)*.
Levegőben lévő légijárműtől származó jelentés, amelyet a helyzetjelentésekre és az operatív és/vagy meteorológiai jelentésekre vonatkozó követelményeknek megfelelően állítottak össze.

Megjegyzés. - Az AIREP űrlap ismertetését a PANS – RAC (Doc 4444) tartalmazza.

Altitude - *Tengerszint feletti magasság*.
Egy felületnek, pontnak vagy pontként értelmezett tárgynak a közepes tengerszinttől mért függőleges távolsága.

ATS direct speech circuit - *A Légiforgalmi Szolgálatok (ATS) közvetlen beszéd-üzemű vonala.*
A légiforgalmi állandóhelyű szolgálat (AFS) távbeszélő-összeköttetési vonala, amely a légiforgalmi szolgálatok (ATS) egységei közötti közvetlen információ cserére szolgál.

Automatic telecommunication log - *Automatikus távközlési napló (állomásnapló).*
Egy légiforgalmi távközlési állomás tevékenységéről elektronikus, vagy mechanikus eszközökkel készített feljegyzések.

Flight level - *Repülési szint*.
Egy azonos légnyomású pontokból álló felület (nyomásfelület), amelyet egy pontosan meghatározott nyomású referenciaszinthez, az 1013,2 hPa-hoz viszonyítanak, és amelyet a többi ilyen felületektől meghatározott légnyomás intervallumok választanak el.

1. Megjegyzés. - Egy barometrikus (nyomás-értéken alapuló) magasságmérő, melyet a Nemzetközi Egyezményes Légkörnek megfelelően kalibrálnak:

a) ha a **QNH** (Tengerszintre Átszámított Légnyomás) referencia nyomás-értéket állítják be rajta, akkor **Tengerszint feletti magasságot (Altitude)** mér;

b) ha a **QFE** referencia nyomás-értéket állítják be rajta, akkor a **Magasságot (Height)** a QFE referencia szint felett méri;

c) ha az 1013,2 hPa referencia nyomásértéket állítják be rajta, akkor használatával a **Repülési Szinteket (Flight level)** lehet mérni.

2. Megjegyzés. - Az előbbi első megjegyzésben használt **"Magasság" ("Height")** és "**Tengerszint feletti magasság" ("Altitude")** *inkább Barometrikus Magasságot és Tengerszint Feletti Magasságot jelent, mint geometriait.*

Frequency channel - *Frekvencia-csatorna.*
A frekvencia-spektrum egy összefüggő, folytonos része, amely egy meghatározott rádiósugárzás fajta felhasználásával adattovábbításra, átvitelre alkalmazható.

Megjegyzés. - A adásfajták osztályozását és az egyes átvitel-típusokhoz megfelelő frekvencia sprektum-tartományokról szóló információkat (sávszélességeket) az ITU Rádiószabályzat S2 cikkelye és az S1 Függelék tartalmazza.

Height - *Magasság (föld feletti).*
Egy felületnek, pontnak vagy pontként értelmezett tárgynak egy meghatározott referenciaszinttől mért függőleges távolsága.

Human performance - *Emberi teljesítőképesség*
Az emberi képességek és ezeknek a képességeknek a korlátai, melyek hatással vannak a légiközlekedés üzemeltetésének biztonságára és hatékonyságára.

Location indicator – *Helységnév-kód.*
Az ICAO által előírt szabályoknak megfelelően kialakított négybetűs kódcsoport, amelyet egy légiforgalmi állandóhelyű állomás helységnevéhez rendelnek hozzá.

Meteorological operational channel - *Meteorológiai operatív csatorna.*
A légiforgalmi állandóhelyű szolgálat (AFS) egy csatornája, amelyet a légiforgalmi meteorológiai tájékoztatások cseréjére használnak.

Meteorological operational telecommunication network - *Meteorológiai operatív távközlési hálózat.*
Meteorológiai operatív csatornák integrált rendszere, amely a légiforgalmi állandóhelyű szolgálat (AFS) részét képezi, és amely légiforgalmi meteorológiai tájékoztatások cseréjére szolgál a hálózaton belüli légiforgalmi állandóhelyű állomások között.

Megjegyzés. - Az "integrált" szó olyan üzemmódot jelent, amely lehetővé teszi, hogy a hálózaton belüli állomások az információkat az előzetesen megállapított menetrend szerint tudják adni és venni.

NOTAM - *NOTAM.*
Bármely légiforgalmi berendezés, szolgálat, eljárás létesítéséről, állapotáról, változásáról, vagy veszély fennállásáról szóló értesítés, amelynek idejében való ismerete elengedhetetlenül szükséges a repülésben érdekelt személyzet részére. Az értesítés szétosztása távközlési eszközökkel történik.

Operational control communications – *Repülésüzemi Felügyeleti Összeköttetések*
Olyan összeköttetések, amelyek egy repülés megkezdése, folytatása, átirányítása vagy befejezése fölötti felügyelet gyakorlásához szükségesek, a légijármű biztonsága, valamint a repülés rendszeressége és hatékonysága érdekében.

Megjegyzés. - Az ilyen összeköttetések általában a légijármű és a légijárművet üzembentartó ügynökség közötti közleményváltásokhoz szükségesek.

Route segment - *Útvonalszakasz*
Egy útvonal vagy egy útvonal része, amelyet általában közbenső leszállás nélkül repülnek végig.

Routing Directory - *(Közlemény) továbbítási útvonal lista*
Egy távközlési központban található lista, amely minden egyes címzetthez hozzárendeli a használandó kimenővonalat.

SNOWTAM - *SNOWTAM*
Különleges NOTAM sorozat, amely a mozgási területen található - veszélyt jelentő - hó, jég, latyak, vagy hóval, latyakkal és jéggel kapcsolatosan keletkező állóvizek okozta körülmények jelenlétéről, vagy eltakarításáról tájékoztat egy erre meghatározott kód-rendszer segítségével.

2. FEJEZET: A NEMZETKÖZI LÉGIFORGALMI TÁVKÖZLÉSI SZOLGÁLATRA VONATKOZÓ ADMINISZTRATÍV ELŐÍRÁSOK

2.1 A szolgálat felosztása

A nemzetközi Légiforgalmi Távközlési Szolgálatot négy részre kell felosztani:

1) Légiforgalmi Állandóhelyű Szolgálat (AFS)

2) Légiforgalmi Mozgó Szolgálat (AMS)

3) Légiforgalmi Rádiónavigációs Szolgálat (ARNS)

4) Légiforgalmi Rádióadó Szolgálat (ABS)

2.2 Távközlés - hozzáférés

Az összes légiforgalmi távközlési állomást, beleértve azokat a végberendezéseket és közbenső berendezéseket is, amelyek egy Légiforgalmi Távközlési Hálózat (ATN) részét alkotják, meg kell védeni az illetéktelen közvetlen hozzáféréstől és távveléréstől.

2.3 Üzemidő

2.3.1 Az Illetékes Hatóság az ellenőrzése alá tartozó, a Nemzetközi Légiforgalmi Távközlési Szolgálat részét képező állomások és irodák szokásos üzemidejéről köteles tájékoztatni azokat a légiforgalmi távközlési képviseleteket, melyeket a többi érintett hivatal az erről szóló tájékoztatások vételére kijelölt.

2.3.2 Amikor ez szükséges és, az Illetékes Hatóság a szokásos üzemidő változásáról köteles tájékoztatni azokat a légiforgalmi távközlési képviseleteket, melyeket a többi érintett hivatal az erről szóló tájékoztatások vételére kijelölt, mielőtt ezek a változások hatályba lépnének. Az ilyen változásokat, amikor szükséges, NOTAM-ban is közzé kell tenni.

2.3.3 Ha a nemzetközi légiforgalmi távközlési hálózat egy állomása, vagy egy légijármű üzemeltetést végző szervezet képviselete változtatást kér egy másik állomás üzemidejében, akkor az ilyen változtatást a lehető leghamarabb kell kérelmezni, miután a változtatás szükségessége ismertté vált. A változtatást kérő állomást, vagy a légijármű üzemeltetést végző szervezet képviseletét minél hamarabb tájékoztatni kell kérésének eredményéről.

2.4 Felügyelet

2.4.1 Minden államnak ki kell jelölnie azt a hatóságot, mely felelősséggel tartozik azért, hogy a nemzetközi Légiforgalmi Távközlési Szolgálat az ezen Anex-ben található eljárásoknak megfelelően üzemeljen.

2.4.2 **Ajánlás –** *Az itt található eljárások alkalomszerűen előforduló megsértését, amikor az nem súlyos, lehetőleg az érintett felek közötti közvetlen kapcsolattal kell lerendezni, akár levelezés, akár személyes találkozás útján.*

2.4.3 Amikor egy állomás ezen eljárásokat súlyosan vagy ismételten megsérti, akkor erről az ezt észlelő hatóság éljen kifogással azon Állam 2.4.1 pont alapján kijelölt hatóságához címezve, amelyhez az állomás tartozik.

2.4.4 **Ajánlás** - *A 2.4.1 pont értelmében kijelölt hatóságok lehetőség szerint cseréljék ki egymás között információikat a távközlési, rádiónavigációs, operatív és karbantartó rendszerek működéséről, a szokatlan sugárzási jelenségekről, stb.*

2.5 Felesleges, szükségtelen adások

Minden Államnak biztosítania kell, hogy a területén lévő állomások szándékosan ne sugározzanak szükségtelen vagy ismeretlen jeleket, közleményeket vagy adatokat.

2.6 Interferencia

Valamennyi hivatal, mielőtt bármely állomás számára ellenőrzések, vagy kísérletek végrehajtását engedélyezne, a káros interferencia elkerülése céljából elő kell írja, hogy az összes lehetséges elővigyázatossági intézkedést tegyék meg, például a frekvencia vagy az adásidő gondos megválasztását, valamint a sugárzási energia csökkentését, vagy ha lehetséges, elnyomását. A ellenőrzések vagy kísérletek eredményeként jelentkező káros interferenciát minél hamarabb meg kell szüntetni.

3. FEJEZET: A NEMZETKÖZI LÉGIFORGALMI TÁVKÖZLÉSI SZOLGÁLAT ÁLTALÁNOS ELJÁRÁSAI

3.1 Általános rész

Az ebben a fejezetben leírt eljárások általános természetűek, és értelemszerűen - ahol megfelelő - az ebben a kötetben található más fejezetekre is alkalmazni kell őket

Megjegyzés. - Az érintett szolgálatokra vonatkozó részletes eljárásokat a 4., 5., 6., 7. és 8. fejezetek tartalmazzák.

3.2 Üzemidő meghosszabbítása; valamint az állomások bezárása

3.2.1 A nemzetközi légiforgalmi távközlési szolgálat állomásainak rendes üzemidejüket szükség szerint meg kell hosszabbítaniuk, úgy, hogy a repülések üzemeltetéséhez szükséges forgalmazást biztosíthassák.

3.2.2 Mielőtt egy állomás bezárna, szándékát közölnie kell az összes olyan állomással, mellyel közvetlen össze- köttetésben áll, meg kell erősítse, hogy nincs szükség üzemidejének meghosszabbítására, valamint közölnie kell az ismételt nyitásának időpontját, ha ez a normál üzemidejétől eltérő.

3.2.3 Ha az állomás rendszeres jelleggel egy közös vonalon lévő hálózatban működik, akkor zárási szándékát vagy az ellenőrzőállomásnak, vagy ha ilyen nincs, akkor a hálózatban található összes többi állomásnak be kell jelentenie. Ezután még két percig figyelésen kell maradnia, és csak akkor zárhat be, ha eközben nem kapott hívást.

3.2.4 Ha egy nem folyamatos üzemben dolgozó állomás kényszerhelyzeti, sürgősségi, jogellenes beavatkozással vagy elfogással kapcsolatos forgalmazással van elfoglalva, vagy várhatóan ilyen forgalmazásban fog részt venni, akkor rendes üzemidejét meg kell hosszabbítania, hogy biztosíthassa eaz zen összeköttetések alátámasztását.

3.3 Közlemények elfogadása, feladása és kézbesítése

3.3.1 A légiforgalmi távközlési szolgálat csak a 4.4.1.1 pontban meghatározott feltételeknek megfelelő közleményeket fogadhat el továbbításra.

3.3.1.1 A közlemény elfogadhatóságának megállapítása annak az állomásnak a felelőssége, ahol a közleményt továbbításra benyújtották.

3.3.1.2 Miután a közleményt elfogadhatónak ítélték, akkor az elsőbbségi besorolásának (prioritásának) megfelelően kell továbbítani, átjátszani és/vagy kézbesíteni, megkülönböztetés, vagy indokolatlan késleltetés nélkül.

3.3.1.3 **Ajánlás.** – *Egy közleményt átjátszó bármely állomást felügyelő hatóság lehetőleg nyújtson be kifogást egy későbbi időpontban a közleményt továbbításra átvevő állomást felügyelő hatóság felé, ha olyan közleményt talált, amelyet elfogadhatatlannak ítélt.*

3.3.2 Csak az olyan közlemények fogadhatók el továbbításra, amelyek a légiforgalmi távközlési szolgálat részét képező állomásnak szólnak, kivéve, ha az érintett távközlési hatósággal erről külön megegyezést kötöttek.

3.3.2.1 Egy közleményt, melyet két vagy több címre küldenek, akár ugyanazon állomáson belül találhatók ezek a címek, akár különböző állomásokon, a 4.4.3.1.2.3 pontban leírtak betartásával egyetlen közleményként kell elfogadni.

3.3.3 A légijárművet üzemeltető ügynökség (járató) számára kezelt közlemények csak akkor fogadhatók el, ha azokat a távközlési állomásnak az illető ügynökség erre felhatalmazott képviselője nyújtja be az ide vonatkozóan előírt formában, vagy abban az esetben, ha a közleményt az ügynökségtől egy jogosítással rendelkező vonalon keresztül kapják.

3.3.4 A Légiforgalmi Távközlési Szolgálat minden állomása számára, mely állomásról egy vagy több légijármű-üzemeltető ügynökségnek (járatónak) közleményeket kézbesítenek, minden légijármű-üzemeltető ügynökség számára ki kell jelölni egy egyedüli irodát, a légiforgalmi távközlési ügynökség és az érintett légijármű-üzemeltető ügynökség közötti megállapodás alapján.

3.3.5 A Nemzetközi Légiforgalmi Távközlési Szolgálat állomásainak feladata az általuk kiszolgált repülőtér(ek) határán belül található címzet(tek)nek a közlemények kézbesítése, továbbá ezeken a határokon kívül csak azon címzet(tek)nek, melyek erre külön megállapodást köthettek az érintett hivatallal.

3.3.6 A közleményeket vagy írásban, vagy más egyéb állandó formában kell kézbesíteni, ahogy azt a hatóság előírta.

3.3.6.1 **Ajánlás.** - *Abban az esetben, ahol a közlemények kézbesítésére telefon-, vagy hangos beszélő rendszert használnak - hangrögzítési lehetőség nélkül -, a közleményt lehetőség szerint minél hamarabb írásban is adják át, a kézbesítés hitelesítéseként.*

3.3.7 Azokat a közleményeket, amelyeket egy, a levegőben lévő légijármű a légiforgalmi mozgó szolgálat részeként adott fel, és amelyeket a légiforgalmi állandóhelyű távközlési hálózaton keresztül kell továbbítani - a közlemény kézbesítésének teljesítése érdekében - a légiforgalmi távközlési állomás az AFTN-en történő feladás előtt, alakítsa azt át a 4.4.2 pontban előírt közlemény-formátumba.

3.3.7.1 Azokat a közleményeket, amelyeket egy, a levegőben lévő légijármű a légiforgalmi mozgó szolgálat részeként adott fel, és amelyeket a légiforgalmi állandóhelyű szolgálat segítségével, de nem az AFTN vonalon keresztül kell továbbítani, a légiforgalmi távközlési szolgálat állomása szintén dolgozza fel újra a 4.4.2 pontban előírt formátumba; kivételt képez, ha a 3.3.5 pont előírásai szerint, a légijárművekről származó közlemények előzetesen meghatározott szétosztása érdekében előzetes és más intézkedések történtek a légiforgalmi távközlési ügynökség és az érintett légijármű-üzemeltető ügynökség között.

3.3.7.2 A levegőben lévő légijárműtől származó, konkrét címzés nélküli közleményeket (beleértve a légijelentéseket is), ha azok meteorológiai tájékoztatást tartalmaznak, késedelem nélkül továbbítani kell a vétel helyével összeköttetésben lévő, társult meteorológiai hivatalnak.

3.3.7.3 A levegőben lévő légijárműtől származó, konkrét címzés nélküli közleményeket (beleértve a légijelentéseket is), ha azok a légiforgalmi szolgálatokkal kapcsolatos tájékoztatást tartalmaznak, késedelem nélkül továbbítani kell a közleményt vevő távközlési állomással összeköttetésben lévő, együttműködő légiforgalmi szolgálati egységnek.

3.3.7.4 **PANS** (Légiforgalmi Szolgálatok Eljárásai) - *A légijelentések AIREP formátumban történő leírásakor az ICAO által erre a célra jóváhagyott adatszabályokat kell alkalmazni, amikor az csak lehetséges.*

Megjegyzés. - A légijelentések összeállítására vonatkozó előírásokat, beleértve az adatszabályokat is, valamint azt, hogy az ilyen jelentések elemeit milyen sorrendben és formátumban kell a légijármű-állomásoknak leadniuk, valamint a légiforgalmi állomásoknak rögzíteniük és újra feladniuk, a PANS-ATM (Doc 4444) tartalmazza.

3.3.7.5 **PANS** (Légiforgalmi Szolgálatok Eljárásai) - *Ha az AIREP formában lévő légijelentéseket távgépíró eszközzel kell továbbítani (beleértve a telexet is), akkor a továbbított szövegnek olyannak kell lennie, ahogy azt a 3.3.7.4 pontban leírásra került*

3.4 Az idő rendszer

3.4.1 A Légiforgalmi Távközlési Szolgálat valamennyi állomásának az Egyeztetett Világ-időt (UTC - Universal Co-ordinated Time) kell használnia. Az éjféli időpontot, ha ez a nap végét jelzi, 2400-val, ha a nap kezdetét jelzi, 0000-val kell leírni.

3.4.2 A dátum-idő csoport hat számjegyből áll; az első kettő a hónap napja, az utolsó négy számjegy pedig az órák és percek UTC-ben.

3.5 Az összeköttetés, forgalmazás rögzítése

3.5.1 Általános rész

3.5.1.1 A Légiforgalmi Távközlési Szolgálat minden állomásán írásos vagy automatikus távközlési naplót kell vezetni, a légijármű-állomást kivéve, amikor az rádiótávbeszélő berendezést használ a közvetlen összeköttetésre egy légiforgalmi állomással, akkor nem kell távközlési naplót vezetnie.

Megjegyzés. - A távközlési napló védelemként szolgál, abban az esetben, ha a kezelő szolgálati tevékenységét kivizsgálás alá kéne vonni. Ez jogi bizonyítékként is használható.

3.5.1.1.1 **Ajánlás**. - *A légiforgalmi állomásoknak a közleményeket a vétel után lehetőleg rögtön fel kell jegyezniük, kivéve, ha egy kényszerhelyzet során a folyamatos kézi feljegyzés késedelmet okozna az összeköttetésben, akkor a közlemények feljegyzését ideiglenesen meg lehet szakítani, majd a lehető legkorábbi alkalmas időpontban be kell fejezni.*

Megjegyzés: - A rádió-távbeszélő összeköttetés esetében kívánatos, hogy hangrögzítés álljon rendelkezésre a kézi rögzítés szüneteltetésének idejére.

3.5.1.1.2 **Ajánlás**. - *Amikor egy légijármű-állomás fedélzetén a kényszerhelyzeti összeköttetésről, káros interferenciáról, vagy az összeköttetés megszakadásáról feljegyzést készítenek, akár egy rádiótávbeszélő naplóban, akár más módon, akkor ehhez a feljegyzéshez lehetőség szerint mellékeljék az időpontot és helyet, valamint a légijármű repülési magasságát is.*

3.5.1.2 Az írásos naplókba csak a szolgálatban lévő kezelők tehetnek bejegyzéseket, kivéve, hogy más személyek, akiknek tudomása van a bejegyzésekkel kapcsolatos tényekről, a naplóban igazolhatják a kezelői bejegyzések pontosságát.

3.5.1.3 Minden bejegyzésnek teljesnek, világosnak, pontosnak és érthetőnek kell lenni. A naplóba ne írjanak fölösleges jegyzeteket, vagy jelöléseket.

3.5.1.4 Az írásos naplókban minden szükséges javítást csak az a személy végezhet el, aki az eredeti bejegyzést írta. A javítást úgy kell elvégezni, hogy a helytelen bejegyzést egy egyenes vonallal (kézzel vagy írógéppel) áthúzza, a javítást névjelével igazolja, és feltünteti a javítás dátumát és időpontját. A javított szöveget az utolsó bejegyzés utáni következő sorba kell írni.

3.5.1.5 Az írásos vagy automatikusan rögzített távközlési naplókat legalább harminc napig meg kell őrizni. Ha a naplókra kivizsgálás, vagy vizsgálat során szükség van, akkor ennél hosszabb ideig is meg kell őket őrizni, egészen addig az időpontig, amikor nyilvánvalóvá válik, hogy nincs rájuk tovább szükség.

3.5.1.6 Az írásos naplókba az alábbi információkat kell bejegyezni:

a) az állomást üzemeltető képviselet /ügynökség/ neve;
b) az állomás azonosítója;
c) dátum;
d) az állomás nyitásának és bezárásának időpontja;

e) minden egyes kezelő aláírása, azon időpontok feltüntetésével, amikor az illető átveszi és befejezi a szolgálatot;

f) a figyelt frekvenciák felsorolása és az egyes frekvenciákon tartott felügyelet típusa (folyamatos vagy menetrend szerinti);

g) azon közbenső mechanikus átjátszó állomások kivételével, ahol ezen paragrafus előírásait nem kell betartani, fel kell jegyezni minden összeköttetést, ellenőrző adást vagy összeköttetési kísérletet, melyekben fel kell tűntetni az összeköttetés szövegét, a befejezés időpontját, azon állomások nevét, amelyekkel felvették a kapcsolatot, és a használt frekvenciát. Az összeköttetés szövegét el lehet hagyni a naplóból, ha a kezelt közlemények másolatai rendelkezésre állnak és a napló részét képezik;

h) fel kell jegyezni minden vészhelyzeti közleményt és a velük kapcsolatban tett intézkedéseket;

i) az összeköttetés körülményeinek és a felmerült nehézségeknek rövid leírását, beleértve a káros interferenciát is. Az ilyen feljegyzéseknek tartalmazniuk kell, ha ez lehetséges, azt az időpontot, amikor az interferenciát tapasztalták, annak jellemzőit, rádiófrekvenciáját, valamint a zavaró jel azonosítását;

j) az összekötetés megszakadásának rövid leírását, amely a berendezések meghibásodása vagy egyéb hiba miatt következett be, megadva az összeköttetés szünetelésének időtartamát és a végrehajtott intézkedéseket;

k) minden egyéb kiegészítő információ leírását, amelyet a kezelő az állomás tevékenységének részeként hasznosnak tart.

3.6 A rádióösszeköttetés felvétele

3.6.1 Minden állomásnak válaszolnia kell a légiforgalmi távközlési szolgálat más állomásai által hozzá intézett hívásokra, és kérésre a közleményváltásban részt kell vennie.

3.6.2 Minden állomásnak a kielégítő szolgáltatás fenntartásához szükséges minimális teljesítménnyel kell sugároznia.

3.7 Rövidítések és kódok használata

3.7.1 A nemzetközi légiforgalmi távközlési szolgálatban rövidítéseket és kódokat akkor lehet használni, amikor azok az alkalomhoz illőek, és használatuk lerövidíti, vagy másképpen segíti az összeköttetést.

3.7.1.1 Ha a közlemények szövegében az ICAO által jóváhagyottakon kívül más rövidítéseket és kódokat is használnak, akkor a közlemény feladójának, a közleményt továbbításra elfogadó távközlési állomás kérésére, ezen állomás rendelkezésére kell bocsátania a használt rövidítések és kódok megfejtését.

Megjegyzés. - Amikor az megfelelő, az ICAO által jóváhagyott rövidítéseket és kódokat használják, például azokat, amelyek a PANS-ABC (Doc 8440-es) kiadványban szerepelnek, akkor ez a 3.7.1.1 pontban leírt előírások alkalmazásának szükségességét feleslegessé teszi.

3.8 Közlemények törlése, érvénytelenítése

3.8.1 A közleményeket a távközlési állomás csak akkor törölheti, ha a törlésre a közlemény feladója felhatalmazta.

4. FEJEZET: LÉGIFORGALMI ÁLLANDÓHELYŰ SZOLGÁLAT (AFS - AERONAUTICAL FIXED SERVICE)

4.1 Általános rész

4.1.1 A légiforgalmi állandóhelyű szolgálat magába kell foglalja az alább felsorolt rendszereket és alkalmazásokat, melyeket a nemzetközi légiforgalmi távközlési szolgálatban a föld-föld (azaz a pont - pont és a pont - több-pont közötti) összeköttetésekben használnak fel:

a) A Légiforgalmi Szolgálatok (ATS) közvetlen élőszavas vonalai és hálózatai;
b) Meteorológiai üzemeltetési vonalak, hálózatok és általános adó-rendszerek;
c) A Légiforgalmi Állandóhelyű Távközlési Hálózat (AFTN);
d) Az ICAO Közös Adattovábbító Hálózata (Common ICAO Data Interchange Network - CIDIN);
e) A Légiforgalmi Szolgálatok (ATS) közleményeket kezelő szolgáltatásai; és
f) A Központok Közötti Összeköttetés (ICC).

1. Megjegyzés: A légiforgalmi szolgálatok (ATS) közvetlen élőszavas vonalaira vonatkozó előírásokat a 4.2 pont foglalja magába.

2. Megjegyzés: A meteorológiai operatív vonalakat és a meteorológiai operatív távközlési hálózatokkal kapcsolatos előírásokat a 4.3 pont tartalmazza.

3. Megjegyzés: Az AFTN "tárol - és – továbbít" közlemény kézbesítő szolgáltatást nyújt szöveges közlemények átvitelére ITA-2 és IA-5 formátumban, karakter-központú eljárások felhasználásával. Az AFTN-re vonatkozó előírásoka 4.4 pontban találhatók.

4. Megjegyzés: Az ICAO Közös Adattovábbító Hálózata (Common ICAO Data Interchange Network - CIDIN) közös továbbító szolgáltatást biztosít mind bináris, mind szöveges közlemények átvitelére, az AFTN és OPMET alkalmazások támogatására. A CIDIN-nel kapcsolatos eljárások szabályait a 4.5 pont tartalmazza.

5. Megjegyzés: Az ATS (Légiforgalmi Szolgálatok) Közleményeit Kezelő Szolgáltatás (ATSMSH - Air Traffic Services Message Handling Services) alkalmazásai lehetővé teszik az ATS közlemények cseréjét a szolgáltatást használók között a Légiforgalmi Távközlési Hálózaton (ATN - Aeronautical Telecommunication Network) és az Internet Összeköttetési Szolgáltatáson (ICS - Internet communication service) keresztül. Az ATS közleményeket kezelő szolgáltatással kapcsolatos előírásokat a 4.6 pont foglalja magába.

6. Megjegyzés: A Központok Közötti Összeköttetési (ICC - inter-cntre communications) alkalmazások lehetővé teszik az információ-cserét az ATS egységek között a Légiforgalmi Távközlési Hálózat (ATN - Aeronautical Telecommunication Network) felhasználásával és az Internet Összeköttetési Szolgáltatáson (ICS - Internet communication service) keresztül, az értesítés, koordináció, irányítás átadás és repüléstervezés, légtérgazdálkodás és az áramlásszabályozás támogatására. A Központok Közötti Összeköttetést érintő előírások a 4.7 pontban találhatóak.

7. Megjegyzés: A Légiforgalmi Távközlési Hálózatnak (ATN - Aeronautical Telecommunication Network) a Légiforgalmi Szolgálatok Közleményeit Kezelő Szolgáltatásai (ATSMSH - Air Traffic Services Message Handling Services) és a Központok Közötti Összeköttetés (ICC - Inter-Centre Communications) alkalmazásai lehetővé teszik a meglevő AFTN és CIDIN felhasználók és rendszerek részére, hogy az ATN rendszerébe integrálódhassanak.

4.1.2 Az AFS közlemények megengedett tartalma

Megjegyzés: A 4.1.2 pont előírásai nem vonatkoznak a Légiforgalmi Szolgálatok közvetlen beszédüzemű vonalain történő összeköttetésekre.

4.1.2.1 A szöveges közleményekben az alábbi karaktereket szabad használni:

Betűk: ABCDEFGHIJKLMNOPQRSTUVWXYZ

Számok: 1 2 3 4 5 6 7 8 9 0

Egyéb jelek:
- (kötőjel)
? (kérdőjel)
: (kettőspont)
((nyitó zárójel)
) (záró zárójel)
. (pont, pont a mondat végén, vagy tizedes pont)
, (vessző)
' (aposztróf)
= (kettős kötőjel, vagy egyenlőségjel)
/ (törtvonal, vagy ferde zárójel)
+ (összeadásjel)

A fent felsoroltakon kívül egyéb karaktereket csak akkor szabad használni a közleményekben, ha az a szöveg megértéséhez feltétlenül szükséges. Ha egyéb jeleket is használtak, azokat pontosan meg kell határozni.

4.1.2.2 A távgépíró vonalakon keresztül történő közleményváltásra a 2. számú Nemzetközi Távíró ABC (ITA-2) alábbi jelei megengedettek:

az 1 – 3-as számú jelek	- betű- és számkészletben is
a 4-es számú jel	- csak betűkészletben
az 5-ös számú jel	- betű- és számkészletben is
a 6 – 8-as számú jelek	- csak betűkészletben
a 9-es számú jel	- betű- és számkészletben is
a 10-es számú jel	- csak betűkészletben
a 11 – 31-es számú jelek	- betű- és számkészletben is

1. Megjegyzés: A "betűkészlet"-en és a "számkészlet"-en a készülék váltóbillentyűjével létrehozott állapotot kell érteni, amely állapotba a csatornához kapcsolt készüléket a jel vétele előtt helyezték.

2. Megjegyzés: A fenti jelek használatakor többek között figyelembe kell venni a 4.4.5.3 pont előírásait is.

3. Megjegyzés: A 4.1.2.2 pont előbb felsorolt előírásai nem kívánják megakadályozni az alábbiak használatát:

a) a 6, 7 és 8-as számú jelek használatát számkészletben, kétoldalú egyezmény megkötését követően, azon Államok között, amelyek közvetlenül egymáshoz kapcsolódó távközlési állomásokkal rendelkeznek, *b) a 10-es számú jel használatát számkészletben, elsőbbségi riasztójelzésként (lásd a 4.4.4.3 pontot); és*

c) a 4-es számú jel használatát számkészletben, csak operatív célra, nem egy közlemény részeként.

4.1.2.3 A távgépíró vonalakon történő közleményváltásra az 5-ös számú Nemzetközi ABC (IA-5) alábbi karakterei a megengedettek:

- a 0/1 – 0/3 közötti és a 0/7-es karakterek – az elsőbbségi riasztójelzésekben (*lásd a* 4.4.15.2.2.5 *pontot*), a 0/10, 0/11-es karakterek a záró karaktersorozatban (*lásd a* 4.4.15.3.12.1 *pontot*), a 0/13-as karakter;
- a 2/0, 2/7 – 2/9, 2/11 – 2/15-ös karakterek;
- a 3/0 – 3/10, 3/13, 3/15-ös karakterek;
- a 4/1 – 4/15-ös karakterek,
- az 5/0 – 5/10-es karakterek; és
- a 7/15-ös karakter.

Megjegyzés: A megelőző 4.1.2.3 pont előbb felsorolt előírásai nem a teljes IA-5-ös ABC használatát kívánják megakadályozni, miután az érintett Hatóságok erről megállapodtak.

4.1.2.4 Római számokat nem szabad használni. Ha egy közlemény feladója arról akarja tájékoztatni a címzettet, hogy római számokat szándékozott írni, akkor arab számokat írjon és tegye eléjük a "ROMAN" (római) szót.

4.1.2.5 Az ITA-2 kóddal leírt közlemények nem tartalmazhatják az alábbiakat:

1) egymás után, megszakítás nélkül következő 26, 3, 26 és 3-as számú jeleket, ebben a sorrendben (sem betűkészletben, sem számkészletben), ez csak a fejlécben fordulhat elő, a 4.4.2.1.1 pont előírásai szerint; és

2) egymás után, megszakítás nélkül következő négy darab 14-es számú jelet (sem betűkészletben, sem számkészletben), ez csak a záró szakaszban fordulhat elő, a 4.4.6.1 pont előírásai szerint.

4.1.2.6 Az IA-5 kóddal leírt közlemények nem tartalmazhatják az alábbiakat:

1) a 0/1 karaktert (SOH), ez csak a fejlécben fordulhat elő, ahogy az a 4.4.15.1.1 a) pont előírásaiban meghatározásra került;

2) a 0/2 karaktert (STX), ez csak a feladó sorban fordulhat elő, ahogy azt a 4.4.15.2.2.7 pont előírja;

3) a 0/3 karaktert (ETX), ez csak a záró-részben fordulhat elő, ahogy az a 4.4.15.3.12.1 pontban előírásra került;

4) egymás után, megszakítás nélkül következő 5/10, 4/3, 5/10 és 4/3 karaktereket, ebben a sorrendben (ZCZC);

5) egymás után, megszakítás nélkül következő 2/11, 3/10, 2/11, és 3/10 karaktereket, ebben a sorrendben (+:+:);

6) egymás után, megszakítás nélkül négyszer következő 4/14 karaktert (NNNN); és

7) egymás után, megszakítás nélkül négyszer következő 2/12 karaktert („„„).

4.1.2.7 A közlemények szövegét nyílt nyelven, vagy a 3.7 pontban előírt rövidítések és kódok használatával kell megfogalmazni. A feladó kerülje a nyílt nyelv használatát, ha a szöveg hossza megfelelő rövidítésekkel és kódokkal csökkenthető. Ne használjon olyan szavakat és kifejezéseket, amelyek nem fontosak .

4.1.2.8 Ha a közlemény feladója a közlemény szövegrészének bizonyos helyein sorigazítási kódot [<≡] kíván küldeni (lásd a 4.4.5.3 és 4.4.15.3.6 pontokat), akkor minden ilyen helyre ki kell írni a [<≡] jelsorozatot.

4.2 Légiforgalmi szolgálatok közvetlen élőszavas összeköttetései (ATS vonalak)

Megjegyzés: A légiforgalmi szolgálatok közvetlen élőszavas közleményváltásaival kapcsolatos előírásokat az Annex 11 - 6. fejezete tartalmazza.

4.3 Meteorológiai operatív csatornák és meteorológiai operatív távközlési hálózatok

A meteorológiai operatív csatornákon és a meteorológiai operatív távközlési hálózatokon használt eljárásoknak összeegyeztethetőeknek kell lenniük a Légiforgalmi Állandóhelyű Távközlési Hálózat (AFTN) eljárásaival.

Megjegyzés: Az "összeegyeztethető" (kompatibilis) olyan üzemeltetési módot jelent, amely biztosítja, hogy a meteorológiai operatív csatornákon váltott közleményeket a légiforgalmi állandóhelyű távközlési hálózaton is le lehessen adni anélkül, hogy annak káros hatása lenne a légiforgalmi állandóhelyű távközlési hálózat működésére és fordítva.

4.4 Légiforgalmi állandóhelyű távközlési hálózat (AFTN)

4.4.1 Általános rész

4.4.1.1 *Közlemények kategóriái.* A 3.3 pont előírásait is figyelembe véve, a légiforgalmi állandóhelyű távközlési hálózatnak az alábbi kategóriákba sorolható közleményeket kell kezelnie:

a) vészhelyzeti közlemények *(distress messages)*;
b) sürgősségi közlemények *(urgency messages)*;
c) repülésbiztonsággal kapcsolatos közlemények; *(flight safety messages)*
d) meteorológiai közlemények;
e) a repülések rendszerességét elősegítő közlemények;
f) a Légiforgalmi Tájékoztató Szolgálat (AIS) közleményei;
g) légiforgalmi adminisztrációs, igazgatási közlemények;
h) szolgálati közlemények.

4.4.1.1.1 *Vészhelyzeti közlemények (SS sürgősségi jelzéssel)*. Ebbe a kategóriába azok a közlemények tartoznak, amelyeket a mozgó állomások adnak föl, és amelyben azt közlik, hogy súlyos és közvetlen veszély fenyegeti őket, valamint minden egyéb olyan közlemény, amely a vészhelyzetben lévő mozgó állomásnak történő azonnali segítségnyújtással kapcsolatos.

4.4.1.1.2 *Sürgősségi közlemények (DD elsőbbségi jelzéssel)*. Ebbe a kategóriába azok a közlemények tartoznak, amelyek egy hajó, légijármű vagy egyéb jármű biztonságával, vagy a fedélzetén, illetve a látótávolságában lévő személy biztonságával kapcsolatosak.

4.4.1.1.3 *Repülésbiztonsági közlemények (FF elsőbbségi jelzéssel)*. Ebbe a kategóriába tartoznak:
a) a légijárművek mozgásával és irányításával kapcsolatos közlemények, ahogy azokat a PANS-ATM (Doc 4444) 10. Fejezete meghatározza;
b) a légijárművet üzemeltető ügynökség (járató) által feladott közlemények, amelyek közvetlenül, haladék nélkül érintenek egy repülésben lévő, vagy indulni készülő légijárművet;
c) a meteorológiai közlemények a SIGMET tájékoztatásra, a különleges légijelentésekre, az AIRMET közleményekre, a vulkáni hamufelhők és trópusi ciklonok tanácsadói információira és az előrejelzések módosításaira korlátozottak..

4.4.1.1.4 *Meteorológiai közlemények (GG elsőbbségi jelzéssel)*.

Ebbe a kategóriába tartoznak:
a) az előrejelzéseket, pl. közelkörzeti/repülőtéri előrejelzéseket (TAF-okat), területi és útvonali előrejelzéseket tartalmazó közlemények;
b) észleléseket és jelentéseket tartalmazó közlemények, mint pl. a METAR és a SPECI.

4.4.1.1.5 *A repülések rendszerességét elősegítő közlemények (GG elsőbbségi jelzéssel)*.

Ebbe a kategóriába tartoznak:

a) légijárművek terhelésével kapcsolatos, a súly és súlypont számításához szükséges közlemények;

b) a légijárművek üzemeltetési menetrendjében beálló változásokkal kapcsolatos közlemények;

c) a légijárművek karbantartásával, szervizelésével kapcsolatos közlemények;

d) az utasokra, személyzetre és árura vonatkozó kollektív követelmények változásával kapcsolatos közlemények, melyek a szokásos üzemeltetési menetrendtől való eltérésre vonatkoznak;

e) a nem tervezett - szokásostól eltérő - leszállásokkal kapcsolatos közlemények;

f) a nem menetrendszerű repülések számára a repülés előtt léginavigációs szolgálatok biztosítását és operatív kiszolgálást kérő közlemények, pl. átrepülési engedély kérése;

g) a légijármű-üzemeltető ügynökségek (járatók) által feladott, a légijármű érkezését, vagy indulását jelentő közlemények;

h) alkatrészekkel vagy anyagokkal kapcsolatos közlemények, melyekre sürgősen szükség van a légijárművek üzemeltetéséhez.

4.4.1.1.6 *Légiforgalmi tájékoztató szolgálat (AIS) közleményei (GG elsőbbségi jelzéssel)*.

Ebbe a kategóriába tartoznak:

a) A NOTAM-okkal kapcsolatos közlemények;

b) A SNOWTAM-okkal kapcsolatos közlemények.

4.4.1.1.7 *Légiforgalmi adminisztratív közlemények (KK elsőbbségi jelzéssel).*

Ebbe a kategóriába tartoznak:

a) a légijárművek üzemeltetésének biztonsága vagy rendszeressége érdekében biztosított létesítmények üzemeltetésével, vagy fenntartásával, karbantartásával kapcsolatos közlemények;

b) a légiforgalmi távközlési szolgálatok működésével kapcsolatos közlemények;

c) a Polgári Légügyi Hatóságok között váltott, a légiforgalmi szolgálatokkal kapcsolatos közlemények.

4.4.1.1.8 Az információ-kérő közleményeket ugyanolyan elsőbbségi jelzéssel kell ellátni, mint amilyennel azt a közleményt láttak el, amellyel kérnek, kivéve, ha a repülés biztonsága érdekében ennél magasabb prioritás indokolt.

4.4.1.1.9 *Szolgálati közlemények (megfelelő elsőbbségi jelzéssel).*

Ebbe a kategóriába tartoznak a légiforgalmi állandóhelyű állomásoktól származó közlemények, amelyekben tájékoztatást vagy megerősítést kérnek más, olyan közleményekkel kapcsolatban, amelyeket a légiforgalmi állandóhelyű hálózat látszólag helytelenül továbbított, vagy amelyekkel a csatorna-sorszámok megerősítését kérik, stb.

4.4.1.1.9.1 A szolgálati közleményeket a 4.4.2 vagy a 4.4.15 pontban előírt formában kell elkészíteni. Amikor a 4.4.3.1.2 vagy a 4.4.15.2.1.3 pont előírásait alkalmazzák egy olyan szolgálati közleményre, amelynek címzettje egy csak helységkóddal azonosított légiforgalmi állandóhelyű állomás, akkor közvetlenül ez után a helységkód után az ICAO három-betűs "YFY" azonosítóját kell beilleszteni, amelyet egy megfelelő nyolcadik betű kövessen.

4.4.1.9.2 A szolgálati közleményeket a megfelelő elsőbbségi jelzéssel kell ellátni.

4.4.1.1.9.2.1 **Ajánlás.** - *Ha a szolgálati közlemények korábban feladott közleményekre vonatkoznak, lehetőleg ugyanazzal az elsőbbségi jelzéssel lássák el, mint az(oka)t, amely(ek)re vonatkoznak.*

4.4.1.1.9.3 Az átviteli hibákat javító szolgálati közleményeket minden olyan címzettnek meg kell küldeni, aki a hibás adást meg fogja kapni.

4.4.1.1.9.4 A szolgálati közleményre adott választ annak az állomásnak kell megcímezni, amely az eredeti szolgálati közleményt feladta.

4.4.1.1.9.5 **Ajánlás.** - *A szolgálati közlemények szövege a lehető legtömörebb legyen.*

4.4.1.1.9.6 A szolgálati közleményeket, kivéve azokat, amelyek SS közlemény vételét nyugtázzák, az SVC rövidítéssel kell azonosítani, amely a szöveg első eleme legyen.

4.4.1.1.9.7 Amikor a szolgálati közlemény egy korábban kezelt közleményre hivatkozik, akkor a korábbi közleményre a megfelelő közlemény-azonosítóval (lásd a 4.4.2.1.1 b) és 4.4.15.1.1. b) pontokat), vagy a feladási időt és a feladót jelző azonosító karaktercsoportok megadásával (lásd a

4.4.4 és a 4.4.15.2.2 pontokat) kell hivatkozni, azokkal, amelyekkel a hivatkozott közleményt egyértelműen meghatározzák.

4.4.1.2 *Elsőbbségi sorrend.*

4.4.1.2.1 A Légiforgalmi állandóhelyű távközlési hálózaton a közlemények továbbításának elsőbbségi sorrendje a következő:

Közlemény továbbításának elsőbbségi sorrendje	*Elsőbbségi jelzés*
1	SS
2	DD FF
3	GG KK

4.4.1.2.2 **Ajánlás.** *Az azonos elsőbbségi jelzéssel rendelkező közleményeket lehetőleg abban a sorrendben továbbítsák, amilyen sorrendben azokat feladásra benyújtották.*

4.4.1.3 *A közlemények továbbítási útvonalának meghatározása*

4.4.1.3.1 Minden közleményt a rendelkezésre álló leggyorsabb továbbítási útvonalon kell a címzettnek leadni.

4.4.1.3.2 A közlemény-forgalom gyorsítására, ha szükséges, előzetes megállapodásokat kell kötni a kitérő útvonalakról. Minden távközlési központnak rendelkeznie kell a megfelelő kitérő útvonal listával, amelyet az érintett távközlési központokat üzemeltető Hatóság(ok) jóváhagyott (jóváhagytak), és szükség esetén ezeket kell használni.

4.4.1.3.2.1 **Ajánlás.-** *Kitérő továbbítási útvonalat kell választani:*

1) egy teljesen automatizált távközlési központban:

a) közvetlenül a vonal megszakadásának észlelése után, ha a forgalmazást egy teljesen automatizált távközlési központon keresztül irányítják át;

b) a vonal megszakadásának észlelésétől számított 10 percen belül, ha a forgalmazást egy nem teljesen automatizált távközlési központon keresztül irányítják át;

2) egy nem teljesen automatizált távközlési központban a vonal megszakadásának észlelésétől számított 10 percen belül.

Ott, ahol nem kötöttek előzetes kétoldalú vagy többoldalú megállapodásokat, az átirányítás szükségességéről az érintetteket szolgálati közleményben kell értesíteni.

4.4.1.3.3 Mihelyt nyilvánvalóvá válik az, hogy a légiforgalmi állandóhelyű szolgálat segítségével nem lehet a közleményt elfogadható időintervallumon belül továbbítani, és amennyiben a közlemény annál az állomásnál van, ahol azt benyújtották, akkor meg kell kérdezni a feladót, hogy milyen intézkedéseket tegyenek, kivéve, ha:

a) erről másképp nem egyezik meg az érintett állomás és a közlemény feladója; vagy

b) léteznek olyan megállapodások, amelyek értelmében a késedelmet szenvedő közleményeket automatikusan átirányítják a kereskedelmi távközlési szolgálatokhoz, a feladó értesítése nélkül.

Megjegyzés.- Az "elfogadható időintervallum" azt jelenti, valószínűnek látszik az, hogy a közleményt nem tudják kézbesíteni a címzettnek az érintett közlemény kategóriájára vonatkozó rögzített átviteli idő- intervallumon belül, vagy, ha ilyen nincs, azon időtartamon belül, amelyben a feladó és az érintett távközlési állomás előzetesen megegyezett.

4.4.1.4 *A közlemények forgalmának felügyelete*

4.4.1.4.1 *A közlemények forgalmának folytonossága.* A vevő állomásnak ellenőriznie kell a bejövő közlemények közlemény-azonosítóját, hogy meggyőződjön róla, az adott csatornán érkező összes közlemény csatorna-sorszáma a helyes sorrendben érkezik-e.

4.4.1.4.1.1 Ha a fogadó állomás azt észleli, hogy egy vagy több csatorna-sorszám hiányzik, teljes szolgálati közleményt kell, hogy küldjön (lásd a 4.4.1.1.9 pontot) az őt megelőző állomásnak, amelyben visszautasítja minden olyan üzenet vételét, amelyet a hiányzó sorszámmal/sorszámokkal adtak fel. Az ilyen szolgálati közlemény szövegének tartalmaznia kell a QTA jelzést, a MIS eljárás-jelzést, amit egy, vagy több hiányzó közlemény-azonosító követ (lásd a 4.4.2.1.1.3 és a 4.4.15.1.1.4 pontokat), valamint a szöveg vége jelet (lásd a 4.4.5.6 és a 4.4.15.3.12 pontokat).

Megjegyzés:- Az alábbi példák a fenti eljárás alkalmazását szemléltetik. A második példában az elválasztó kötőjel (-) nyílt szövegben azt jelenti, hogy valamennyitől - valameddig.

1) ha egy csatorna-sorszám hiányzik:
SVC→QTA→MIS→ABC↑123↓<≡

2) ha több csatorna-sorszám hiányzik:
SVC→QTA→MIS→ABC↑123-126↓<≡

4.4.1.4.1.1.1 Amikor a 4.4.1.4.1.1 pont előírásait alkalmazzák, a szolgálati közlemény segítségével a hiányzó közlemény(ek)ről értesített állomás újbóli felelőssége lesz azon közlemény(ek) ismételt továbbítása, amelye(ke)t már korábban a hivatkozott sorszámmal továbbított, és ez(eke)t a közlemény(eke)t új (sorrendileg helyesen következő) közlemény-azonosítóval köteles újra továbbítani. A fogadó állomásnak úgy kell szinkronizálnia, hogy a következő várható csatorna-sorszám az utolsó sikeresen vett csatorna-sorszám plusz egy legyen.

4.4.1.4.1.2 **Ajánlás.-** *Ha a fogadó állomás azt észleli, hogy egy közlemény csatorna-sorszáma kisebb a vártnál, akkor erről lehetőleg értesítse az őt megelőző állomást az alábbi szövegű szolgálati közleménnyel:*

1) az SVC rövidítés;

2) az LR eljárás-jelző, amelyet a vett közlemény-azonosító követ;

3) az EXP eljárás-jelző, amelyet a várt közlemény-azonosító követ;

4) a szöveg vége jel (ETX).

Megjegyzés:- A következő példa mutatja be a fenti eljárás alkalmazását:

SVC→LR→ABC→123→↓EXP→ABC↑135↓<≡

4.4.1.4.1.2.1 **Ajánlás**.- *Amikor a 4.4.1.4.1.2 pont előírásait alkalmazzák, a sorrenden kívüli közleményt vevő állomás lehetőleg úgy szinkronizálja a vételi sorát, hogy a következő várt csatorna-sorszám az utoljára sikeresen vett csatorna-sorszám plusz egy legyen! Az előző állomás lehetőség szerint ellenőrizze a kimenő csatorna-sorszámait, és ha szükséges, javítsa azok sorrendjét!*

4.4.1.4.2 *Eltévedt közlemények*

Megjegyzés: Egy közleményt akkor kell eltévedtnek tekinteni, ha nincs benne semmi olyan közvetlen, vagy közvetett továbbítási utasítás, amely alapján a vevő-állomás intézkedni tudna.

4.4.1.4.2.1 Ha a vevő-állomás azt észleli, hogy eltévedt közlemény került hozzá, akkor
1) vagy szolgálati közleményt küld (lásd a 4.4.1.1.9 pontot) az előző állomásnak, amelyben visszautasítja az eltévedt közlemény vételét;
2) vagy magára vállalja a közlemény továbbítását valamennyi megjelölt címzettnek.

Megjegyzés:- Az 1)-es módszer a kézi ("tépett szalagos") átjátszó állomások esetében javasolható, vagy a folyamatos szalaggal dolgozó félautomata átjátszó-állomások esetén. A 2)-es módszer a teljesen automatikus átjátszó-állomások esetében, vagy a folyamatos szalagot nem használó félautomata állomások esetében lehet célravezető.

4.4.1.4.2.2 Amikor a 4.4.1.4.2.1 pont 1)-es alpontjának előírásait alkalmazzák, akkor a szolgálati közleménynek az SVC rövidítésből, a QTA jelzésből, az MSR eljárás-jelzésből kell állnia, melyeket az eltévedt közlemény azonosítója (lásd a 4.4.2.1.1.3 és a 4.4.15.1.1.4 pontokat) és a szöveg vége jel (lásd a 4.4.5.6 és a 4.4.15.3.12 pontokat) követ.

Megjegyzés:- Az alábbi példa a fenti eljárás alkalmazását mutatja be:

SVC→QTA→MSR→ABC↑123↓<≡

4.4.1.4.2.3 Amikor a 4.4.1.4.2.2 pont alkalmazásának következményeképpen egy feladó állomás szolgálati közlemény útján értesül róla, hogy az egyik közlemény eltévedt, akkor újra át kell vennie a közleményért a felelősséget, és szükség szerint újra fel kell adnia a helyes kimenő csatornán vagy csatornákon.

4.4.1.4.3 Ha egy vonal szakadttá válik, de alternatív lehetőségek rendelkezésre állnak, az érintett állomások kölcsönös közlemények segítségével tájékoztatják egymást az utolsó küldött és vett közlemények csatorna-sorszámáról. Az ilyen közleményváltást teljes szolgálati közlemények formájában (lásd a 4.4.1.1.9 pontot) kell végrehajtani, amelyek szövegének tartalmaznia kell az SVC rövidítést, az LR és LS eljárás-jelzéseket, amelyeket a kérdéses közlemény(ek) azonosítója követ, és a szöveg vége jel (lásd a 4.4.5.6 és a 4.4.15.3.12 pontokat).

Megjegyzés: Az alábbi példa a fenti eljárás alkalmazását szemlélteti:

SVC→LR→ABC↑123↓→LS→BAC↑321↓<≡

4.4.1.5 *Az összeköttetés meghibásodása*

4.4.1.5.1 Ha az összeköttetés bármely állandóhelyű vonalon meghibásodik, az érintett állomásnak - amilyen hamar csak lehetséges, -meg kell kísérelnie az összeköttetés helyreállítását.

4.4.1.5.2 **Ajánlás**.- *Ha az összeköttetést elfogadható időn belül nem lehetséges helyreállítani a szabvány állandóhelyű szolgálati vonalon, akkor lehetőleg egy alkalmas alternatív vonalat kell* *használni. Amennyiben lehetőség van rá, meg kell kísérelni az összeköttetés felvételét az állandóhelyű szolgálat bármely rendelkezésre álló, erre feljogosított vonalán.*

4.4.1.5.2.1 Ha ezek a kísérletek sikertelenek maradnak, akkor csak kivételes és ideiglenes intézkedésként megengedhető bármely rendelkezésre álló levegő/föld frekvencia használata, ha biztosítható, hogy ez a repülésben lévő légijárműveket nem zavarja.

4.4.1.5.2.2 Ha egy rádióösszeköttetés a jel fokozatos elhalkulása, vagy kedvezőtlen terjedési viszonyok miatt megszakad, akkor az általában használatos szabvány állandóhelyű szolgálati frekvencián folyamatos vételi figyelést kell tartani. Annak érdekében, hogy ezen a frekvencián az összeköttetést minél hamarabb helyre lehessen állítani, le kell adni az alábbiakat:

a) a DE eljárás-jelzést;
b) az adóállomás azonosító jelét, háromszor egymás után;
c) a szövegigazítási jelet [<≡]
d) az RY betűket szünet nélkül, annyiszor egymás után, amennyi a papír példányon három sort megtölt;
e) a szövegigazítási jelet [<≡]
f) a "közlemény vége" jelet (NNNN).

A fenti jelsorozatot szükség szerint lehet ismételni.

4.4.1.5.2.3 Ha egy állomás az összeköttetési vonalban vagy a berendezések működésében hibát észlel, azonnal értesítse azokat az állomásokat, amelyekkel közvetlen összeköttetésben van, ha a hiba miatt ezeknek az állomásoknak módosítaniuk kell a közlemények útvonalát. A rendes üzemi körülmények helyreállásáról szintén értesítést kell küldeni ugyanezeknek az állomásoknak.

4.4.1.5.3 Amikor a kitérő útvonalra irányított forgalmazást nem fogadják el automatikusan, vagy ha előre meghatározott kitérő útvonalakat nem jelöltek ki, akkor ideiglenes kitérő útvonalat kell meghatározni szolgálati közlemények cseréjének segítségével. Az ilyen szolgálati közlemények tartalma:
1) az SVC rövidítés;
2) a QSP eljárás-jelzés;
3) ha szükséges, az RQ, NO vagy CNL eljárás-jelzések, kitérő útvonal kérésére, visszautasítására vagy törlésére;
4) azoknak az útvonal-körzeteknek, Államoknak, területeknek, helységeknek vagy állomásoknak az azonosítói, amelyekre a kitérítés vonatkozik;
5) a szöveg vége (ETX) jel.

Megjegyzés: Az alábbi példák mutatják be a fent említett eljárások alkalmazását:
a) kitérő útvonal kérése :
SVC→QSP→RQ→C→K→BG→BI↓<≡

b) kitérő útvonal elfogadása:

SVC→QSP→C→K→BG→BI↓<≡

c) kitérő útvonal elutasítása:

SVC→QSP→NO→C→K→BG→BI↓<≡

d) kitérő útvonal törlése:

SVC→QSP→CNL→ C→K→BG→BI↓<≡

4.4.1.6 *Az AFTN forgalmazási jegyzőkönyvek hosszú-távú tárolása.*

4.4.1.6.1 Minden közleményt, amelyet az AFTN feladó állomás leadott, teljes egészében meg kell őrizni legalább 30 napig.

Megjegyzés. - Bár az AFTN feladó állomás felelős annak biztosításáért, hogy az AFTN forgalmazás rögzítve legyen, nem feltétlenül ez az az egység, ahol a jegyzőkönyveket vezetik és őrzik. Helyi megállapodás alapján az érintett Állam megengedheti, hogy ezeket a feladatokat a közlemények feladói végezzék el.

4.4.1.6.2 Az AFTN vevő állomásoknak legalább 30 napig meg kell őrizniük mindazon feljegyzéseket, amelyek alapján valamennyi vett közleményt és az ezekkel kapcsolatban tett intézkedéseket azonosítani lehet.

Megjegyzés. - A 4.4.1.6.2 pontnak a közlemények azonosítására vonatkozó előírását a közlemények fejlécének, valamint cím és feladó részének feljegyzésével lehet teljesíteni.

4.4.1.6.3 **Ajánlás.-** *Az AFTN távközlési központok lehetőség szerint legalább 30 napig őrizzék meg azokat a feljegyzéseket, amelyek alapján minden átjátszott vagy újra-feladott közleményt és az ezekkel kapcsolatban tett összes intézkedést azonosítani lehet.*

1.Megjegyzés. - A 4.4.1.6.3 pontnak a közlemények azonosítására vonatkozó előírását a közlemények fejlécének, valamint cím és feladó részének feljegyzésével lehet teljesíteni.

2.Megjegyzés. - Az AFTN forgalmazási jegyzőkönyvek AFTN távközlési központokban történő rövid távú megőrzéséről a 4.4.1.7 pont rendelkezik.

4.4.1.7 *Az AFTN forgalmazási jegyzőkönyvek rövid távú megőrzése*

4.4.1.7.1 A 4.4.1.7.2 pontban leírtak kivételével, az AFTN távközlési központoknak legalább egy órán át meg kell őrizniük minden olyan közlemény teljes másolatát, melyet az adott központ átjátszott vagy újra feladott.

4.4.1.7.2 Amennyiben az AFTN távközlési állomások között nyugtázás történik, akkor az átjátszó állomás úgy tekinthető, hogy a továbbiakban nem felelős azon közlemények újra feladásáért vagy ismétléséért, amelyekre pozitív nyugtázást kapott, és így azt a feljegyzéseiből törölheti.

Megjegyzés. - Az AFTN forgalmazási jegyzőkönyveknek az AFTN távközlő központokban történő hosszú távú megőrzéséről a 4.4.1.6 pont rendelkezik.

4.4.1.8 Az AFTN csatornákon történő ellenőrzések eljárásai

4.4.1.8.1 **Ajánlás**.- *Az AFTN csatornákon ellenőrzés és vonal-javítás céljából leadott ellenőrző közlemények lehetőleg az alábbiakat tartalmazzák:*
1) a közlemény eleje jel;
2) a QJH eljárás-jel;
3) a feladó azonosítója;
4) az ITA-2 kód használata esetén az RY karakter, vagy az IA-5 kód használata esetén az U(5/5) *(2/10) karakterek sorozata három sorban egymás után; és
5) a "közlemény vége" jel.

4.4.2 Közlemény-formátumok - 2-es számú Nemzetközi Távíró ABC (ITA-2)

A 4.4.1.8 és a 4.4.9.3 pontokban előírtak kivételével minden közleménynek a 4.4.2.1-től a 4.4.6.1-ig terjedő pontokban előírt elemeket kell tartalmaznia.

1.Megjegyzés: Az ITA-2 közlemény-formátumot a 4-1. ábra mutatja be.

2.Megjegyzés: A következőkben leírt, közlemény-formátumra vonatkozó szabványokban az alábbi szimbólumokat használtuk a 2-es sz. Nemzetközi Távíró ABC bizonyos karaktereihez rendelt funkciók megjelölésére (lásd a III. Kötet, 1 Rész, 8.2.1 pontját és a 8-1. táblázatát):

Szimbólum	*Jelentés*
<	KOCSI VISSZA (*27-es számú jel*)
≡	SOREMELÉS (*28-as számú jel*)
↓	BETŰVÁLTÓ (*29-es számú jel*)
↑	SZÁMVÁLTÓ (*30-as számú jel*)
→	SZÓKÖZ (*31-es számú jel*)

4.4.2.1 *Fejrész*

4.4.2.1.1 A fejrésznek az alábbi elemekből kell állnia:
a) "közlemény eleje" jelzés, a **ZCZC** karakterek;
b) a közlemény azonosítója, amelynek elemei:
1) a vonal /áramkör/ azonosítója;
2) a csatorna-sorszám.
c) további szolgálati információk (ha szükséges), amelynek elemei:
1) egy SZÓKÖZ;
2) legfeljebb tíz karakter.
d) jelköz.

4.4.2.1.1.1. A vonal azonosítója az adóállomás által kiválasztott és hozzárendelt három betűből kell, hogy álljon; az első betű a vonal adóállomás felöli végét, a második a vonal vevő-állomás felöli végét azonosítja, a harmadik pedig a csatornát. Ahol az adó- és a vevőállomás között csak egyetlen csatorna létezik, akkor erre a célra az "A" betűt kell használni. Ha az állomások között több csatorna is van, akkor a csatornákat az "A", "B", "C", stb. betűkkel kell azonosítani, a megfelelő sorrendben.

4.4.2.1.1.2 A távközlési állomásoknak 001 és 000 (az 1000 helyett) közötti háromjegyű, sorrendben növekvő csatorna-sorszámokat kell kijelölni valamennyi, közvetlenül egyik állomástól a másiknak küldött közleményhez. Minden csatornán külön sorszámozást kell alkalmazni, és minden nap 0000 órakor új sorozatot kell kezdeni.

4.4.2.1.1.2.1 **Ajánlás.-** *Hogy elkerüljék ugyanazon sorszámok ismétlődését 24 órán belül, megengedhető a négy-jegyű csatorna-sorszámok használata, amennyiben erről a vonal üzemeltetéséért felelős hatóságok megállapodást kötnek.*

4.4.2.1.1.3 A közlemény-azonosítót a vonalon a következő sorrendben kell leadni:
a) SZÓKÖZ [→];
b) az adó végberendezés betűjele;
c) a vevő végberendezés betűjele;
d) csatorna-azonosító betű;
e) SZÁMVÁLTÓ [↑];
f) csatorna-sorszám (3 számjegy).

4-1. ábra: Az ITA-2 közlemény-formátum

<table>
<tr><th colspan="2">Közlemény rész</th><th>A közlemény rész összetevője</th><th>Az összetevő eleme</th><th>Távgépíró jele</th></tr>

		Szalagemelés (lásd 4.4.7)	További betűváltó jelek azokban az esetekben, ha előzetes megállapodásokat kötöttek arra, hogy a bejövő vonalakon szalagemelést kell alkalmazni (lásd 4.4.7)	

(a fenti ábra a 4.4.2 - 4.4.9.1 pontokban leírt távgépíró közlemény formátumát mutatja be)

Jelmagyarázat:

Szimbólum	*Jelentés*
< KOCSI VISSZA	(27-es számú jel)
≡ SOREMELÉS	(28-as számú jel)
↓ BETŰVÁLTÓ	(29-es számú jel)
↑ SZÁMVÁLTÓ	(30-as számú jel)
→ SZÓKÖZ	(31-es számú jel)

4.4.2.1.2 A távgépíró üzemben közvetlenül a 4.4.2.1.1.3 pontban leírt közlemény-azonosító után egy jelköz jelet kell küldeni, amely öt darab SZÓKÖZ-ből [→→→→→] és egy BETŰVÁLTÓ-ból áll [↓].

Megjegyzés:- Az alábbi példák a közlemény-azonosítóra vonatkozó szabványok (lásd a 4.4.2.1.1 b) és a 4.4.2.1.1.3 pontot) alkalmazását mutatják be:

Szalag *Nyomtatott példány*

→GLB→039→→→→→↓ **GLB039**

(Ez azt jelenti, hogy ez volt aznap a 39. közlemény, amit a vonal "B" csatornáján továbbítottak a "G" állomástól az "L" állomásnak.)

4.4.2.1.3 A közlemény-azonosító után további szolgálati tájékoztatás beszúrását meg kell engedni, amennyiben a vonal üzemeltetéséért felelős hatóságok erről megállapodást kötöttek. Az ilyen további szolgálati információt egy SZÓKÖZ-zel kell kezdeni és utána legfeljebb tíz karakter állhat, és nem foglalahatnak kijelölési funkciót (<≡) magukba.

4.4.2.1.4 **Ajánlás**.- *Hogy elkerülhető legyen a kitérő útvonalra vonatkozó jelzés téves értelmezése (különösen, ha figyelembe vesszük, hogy a fejrész az átvitel során részlegesen sérülhet is), a fejrészben sehol ne forduljon elő egymás után két 22-es számú jel (sem betűkészletben, sem számkészletben).*

4.4.3 Címzés

4.4.3.1 A címnek az alábbi elemeket kell magába foglalnia:
a) kijelölési funkció [<≡];
b) elsőbbségi jelzés;
c) címzett(ek) megjelölése;
d) kijelölési funkció [<≡].
4.4.3.1.1 Az elsőbbségi jelzésnek a feladó által hozzárendelt, megfelelő két betűből kell állnia, a következő szabályok szerint:

A közlemény kategóriája	*Elsőbbségi jelzés*
*vész*helyzeti közlemények (lásd 4.4.1.1.1)	SS
sürgősségi közlemények (lásd 4.4.1.1.2)	DD
repülésbiztonsági közlemények (lásd 4.4.1.1.3)	FF
meteorológiai közlemények (lásd 4.4.1.1.4)	GG
a repülések rendszerességét elősegítő közlemények (lásd 4.4.1.1.5)	GG
légiforgalmi tájékoztató szolgálatok közleményei (lásd 4.4.1.1.6)	GG
légiforgalmi adminisztratív közlemények (lásd 4.4.1.1.7)	KK
szolgálati közlemények (lásd 4.4.1.1.9)	*(ahogy megfelelő)*

4.4.3.1.2 A címzett megjelölése - amely elé közvetlenül egy SZÓKÖZ-t kell tenni, kivéve, ha az a címzés második vagy harmadik sorának első címzett-jelölése - az alábbi elemekből kell, hogy álljon:

a) a célállomás helyének négybetűs helységnév azonosító kódja;

b) a címzett szervezetet/funkciót (légiforgalmi hatóság, szolgálat vagy légijármű üzemeltető ügynökség) azonosító három-betűs kód;

c) még egy betű, amely a címzett szervezeten/funkción belül egy osztályt, részleget, vagy eljáró egységet azonosít. Ha nincs szükség ilyen konkrét megjelölésre, akkor az X betű használható.

1. Megjegyzés. - A négy-betűs helység jelölések jegyzékéz a Doc 7910 - "Helység Jelölések" *tartalmazza.*

2. Megjegyzé. -: A három-betűs kódokat a Doc 8585 - "Légijármű-üzemeltető ügynökségek, légiforgalmi hatóságok és szolgálatok kódjai" *tartalmazza.*

4.4.3.1.2.1 Ha egy közleményt olyan szervezetnek kell címezni, amelynek nem osztottak ki. a 4.4.3.1.2 pontban említett típusú ICAO három-betűs azonosító kódot, akkor a célállomás négy-betűs helység jelölése után az ICAO három-betűs YYY kódot (vagy, katonai szervezet vagy szolgálat esetében az ICAO három-betűs YXY kódot) kell írni. A címzett szervezet nevét ilyenkor a közlemény szövegrészének első elemeként kell feltűntetni. Az ICAO három-betűs YYY vagy YXY kód után a következő (nyolcadik) betűnek a helykitöltő X betűnek kell lennie.

4.4.3.1.2.2 Ha a közleményt egy, a levegőben repülő légijárműnek kell megcímezni, és a közlemény, mielőtt a légiforgalmi mozgó szolgálat továbbítaná, az útjának egy részét az AFTN hálózaton keresztül teszi meg, akkor annak a légiforgalmi állomásnak a helység jelölése után, amelynek továbbítania kell a közleményt a légijármű részére, az ICAO hárombetűs ZZZ kódot kell írni. Ezután a légijármű azonosítóját a közlemény szöveg-részének első elemeként kell feltüntetni. Az ICAO hárombetűs ZZZ kód után a következő (nyolcadik) betűnek a helykitöltő X betűnek kell lennie.

Megjegyzés. - Az alábbi példák a 4.4.3.1.2.1 és a 4.4.3.1.2.2 pontokban leírt szabványok alkalmazását mutatják be:

1) címzett-jelölések (lehetséges típusok):

LGATZTZX	repülőtéri irányító torony (ZTZ) az LGAT helységben /Athén/;
LGATYMYF	a meteorológiai hivatal (YMY) "F" egysége az LGAT helységben;
LGATKLMN	a KLM légijármű-üzemeltető "N" jelű részlege az LGAT helységben;
LGATYYYX	az a légijármű-üzemeltető ügynökség, amelynek neve a közlemény szövegének elején szerepel, és amelynek iroda-helyiségét az LGAT állomás szolgálja ki;
LGATZZZX	a légiforgalmi állomásnak (LGAT) továbbítania kell ezt a közleményt, a légiforgalmi mozgó szolgálat útján, annak a légijárműnek, amelynek azonosítója a közlemény szövegének elején szerepel.

2) az ICA0 három-betűs YYY kód használata:

Az alábbi példában egy fiktív közleményt mutatunk be, amelyet (mondjuk) a "Pingvin Légitársaságnak" címeztek NCRG-be, és a feladó ugyanennek a légijármű-üzemeltető ügynökségnek a PHNL-beli irodája. A példa a közleményt a géptávíró nyomtatott példányán mutatja be, a fejrész és a befejező rész nélkül:

(Cím)	*GG NCRGYYYX*
(Feladó)	*311521 PHNLYYYX*
(Szöveg)	*AIR PENGUIN FLIGHT 801 CANCELLED*
	(= az AIR PENGUIN 801-es járat törölve)

3) az ICAO három-betűs ZZZ kód használata:

Az alábbi példában egy fiktív közleményt mutatunk be, amelyet a GABCD légijárműnek címeztek, az NZAA légiforgalmi állomás útján, a feladó az NZZC körzeti irányító központ. A példa a közleményt a géptávíró nyomtatott példányán mutatja be, fejrész és befejező rész nélkül:

(Cím)	*FF NZAAZZZX*
(Feladó)	*031451 NZZCZQZX*
(Szöveg)	*GABCD CLR DES 5000FT HK NDB*
	(= GABCD, a süllyedés engedélyezve 5000 lábra HK NDB-re)

4.4.3.1.2.3 A teljes címzést a nyomtatott példányon legfeljebb három sorra kell korlátozni, és - a 4.4.14 pontban leírtak kivételével - minden címzettet külön meg kell jelölni, akár ugyanazon a helyen találhatóak, akár nem.

4.4.3.1.2.3.1 Ha a közleményeket nyomtatott példányban nyújtják be továbbításra, és több címzettet is tartalmaznak, mint amennyi három sorban elfér a nyomtatott formátumon, az ilyen közleményeket továbbítás előtt két, vagy több közleménnyé kell átalakítani, melyek egyenként meg kell, hogy feleljenek a 4.4.3.1.2.3 pont előírásainak. Az átalakítás során a címzettek megjelölését - amennyire csak lehetséges - olyan sorrendben kell feltüntetni, amely biztosítja, hogy a következő távközlési központokban a lehető legkevesebb számú újra-feladásra legyen szükség.

4.4.3.1.2.3.2 A távgépíró-vonalakon a közlemény cím-részében a címzetteket megjelölő csoportok minden sorának befejeződése után egy kijelölési funkciót kell küldeni [<≡].

4.4.4 Feladó

A feladó résznek az alábbi elemekből kell állnia:
a) feladási idő;
b) a feladó megjelölése;
c) elsőbbségi jel (ha szükséges);
d) választható fejrész mező;
e) kijelölési funkció [<≡].

4.4.4.1 A feladási idnek hat számjegyű dátum-időpont karakter-csoportból kell felépülnie,, amely a közlemények továbbításra való benyújtásának dátumát és időpontját jelzi (lásd a 3.4.2 pontot); távgépíró-üzemben a feladási időt egy BETŰVÁLTÓT [↓]-nak kell követnie.

4.4.4.2 A feladó azonosítója, amelyet közvetlenül egy SZÓKÖZ [→] előz meg, az alábbi elemekből épül fel:

a) annak a helynek a négy-betűs helység jelölése, ahol a közleményt feladták;

b) a közleményt feladó szervezet/hatáskör (légiforgalmi hatóság, légiforgalmi szolgálat vagy légijármű-üzemeltető ügynökség) három-betűs azonosító jelzése;

c) még egy betű, amely a feladó szervezet/hatáskör egy osztályát, részlegét vagy egységét, eljárását jelzi. Ha ilyen konkrét megadott azonosításra nincs szükség, akkor az "X" betű beszúrásával kell a címzést befejezni.

4.4.4.2.1 Ha a közleményt olyan szervezet küldi, amelynek nem osztottak ki. a 4.4.4.2 b) pontban leírt típusú ICAO három-betűs azonosító jelölést, akkor a feladás helyét jelző négy-betűs helység jelölés után közvetlenül az ICAO három-betűs YYY jelölést kell írni, amelyet a X betű követ (illeetve katonai szervezet vagy szolgálat esetében az ICAO három-betűs YXY jelölést, amelyet a helykitöltő X betű követ). A szervezet (vagy katonai szolgálat) nevét később a közlemény szövegének első elemeként kell feltűntetni.

4.4.4.2.2 Amennyiben a közleményt levegőben repülő légijármű adta fel, és a közlemény útjának egy részét az AFTN hálózaton teszi meg, mielőtt kézbesítik, a feladó csoportban azt a légiforgalmi állomást kell megjelölni, amelyik a közleményt az AFTN-hez továbbította, ami után közvetlenül az ICAO három-betűs ZZZ jelölés és a helykitöltő X betű következik. A légijármű azonosító jelét (hívójelét) a közlemény szövegének első elemeként kell feltűntetni.

4.4.4.2.3 Az AFTN-en továbbított olyan közlemények számára, amelyeket egy másik hálózatban adtak föl, ki kell jelölni egy érvényes AFTN feladó megjelölést, amelyet - megegyezés alapján - az AFTN hálózatot a külső hálózattal összekötő közvetítő, vagy kapu- (gateway) berendezés használ.

Megjegyzés:- Az alábbi példa a 4.4.4.2.2 pontban leírt eljárás alkalmazását mutatja be, egy fiktív közleménnyel, amelyet a KLM153 hívójelű légijármű adott fel, a CZEG-ben található Körzeti Irányító Központnak (ACC-nek) címezve, és a közleményt a CYCB-ben lévő légiforgalmi állomáson keresztül küldik el. A példa a közleményt a távgépíró nyomtatott formájú példányán mutatja, a fejrész és a zárórész nélkül:

(Cím)	*FF CZEGZRZX*
(Feladó)	*031821 CYCBZZZX*
(Szöveg)	*KLM153 [a szöveg hátralevő része, ahogy azt a légijárműtől vették]*

4.4.4.3 Az elsőbbségi jelzést csak a vészhelyzeti közlemények esetén kell használni. Ha használják, akkor az alábbi elemekből kell, hogy álljon, az alábbi sorrendben :
a) SZÁMVÁLTÓ [↑];
b) ÖT darab 10-es számú jel egymás után (szám-készletben);
c) BETŰVÁLTÓ [↓].

1. Megjegyzés. - A 2. számú Nemzetközi Távíró ABC 10-es számú jelének szám-készletbeli alakja általában megegyezik a légiforgalmi állandóhelyű vonalakon használatos távgépírókon a "J" betű szám-készletbeli alakjával.

2. Megjegyzés. - Az elsőbbségi riasztó jelzés a vevő távgépíró-állomáson megszólaltatja a csengőt. A teljesen automatizált állomások hasonló figyelmeztető jelzést adhatnak az SS sürgősségi jelzés észlelésekor. Ezek a jelzések hívják fel az automata átjátszó központokban a felügyelő személyzet, az alárendelt állomásokon pedig kezelő személyzet figyelmét arra, hogy a közlemény azonnali figyelmet követel.

4.4.4.4 A feladó sorban további adatok közlését is meg kell engedni, feltéve hogy a feladó rész teljes hossza nem haladja meg a 69 karaktert, és hogy ez az érintett hatóságok megállapodásának tárgyát kell, hogy képezze.

4.4.4.4.1 **Ajánlás.-** *A szabadon választható adatok jelenlétét lehetőleg egy szóközzel jelezzék, az adatokat egy kijelölési funkcióval zárják le.*

4.4.4.4.2 **Ajánlás.-** *Ha egy közleményben a forrás és a cél címzések között további címzési információk cseréje szükséges, akkor azt lehetőleg a szabadon választható adatmezőben (ODF) tegyék, az alábbi meghatározott formátumban:*
a) a kiegészítő címzés funkció paraméter-kódját egy egyes számmal és egy ponttal (1.) kell jelezni;
b) ezután három módosító karakter és egy egyenlőségjel (=) következik, majd a kiadott 8-karakteres ICAO címzés; és
c) a kiegészítő címzés paraméter-mezőjét egy kötőjellel (-) zárják le.

4.4.4.4.2.1 **Ajánlás.-** *Ha a szolgálati közleményekre, vagy kérdésekre a külön cím nem egyezik meg a feladó megjelölésével, akkor lehetőleg az SVC módosító jelzést kell használni.*

4.4.4.5 A feladó részt egy kijelölési funkcióval [<≡] kell lezárni.

4.4.5 Szöveg

4.4.5.1 A közlemények szövegét a 4.1.2 pont előírásainak megfelelően kell megfogalmazni.

4.4.5.2 Ha a feladóra utaló hivatkozást használnak, akkor az a szövegrész elején kell legyen, kivéve a 4.4.5.2.1 és a 4.4.5.2.2 pontban leírtak esetét.

4.4.5.2.1 Ha a címzett-megjelölés második elemét az YXY, YYY vagy ZZZ három-betűs ICAO jelölés alkotja (lásd a 4.4.3.1.2.1 és a 4.4.3.1.2.2 pontokat), és ezért szükség van a szövegben a közlemény címzettjének pontos meghatározására, akkor ezt az azonosító karakter-csoportot a feladóra való hivatkozás elé kell írni (ha van ilyen), és ezzel ez a szöveg első eleme lesz.

4.4.5.2.2 Ha a feladó-megjelölés második elemét az ICAO három-betűs YXY, YYY vagy ZZZ jelölés alkotja (lásd a 4.4.4.2.1 és a 4.4.4.2.2 pontokat), és ezért szükség van a szövegben azon szervezet (vagy katonai szolgálat), vagy légijármű nevének közlésére, amely a közleményt feladta, akkor ezt az azonosítót a szöveg első elemeként kell beilleszteni a közleménybe.

4.4.5.2.3 Amikor a 4.4.5.2.1 és a 4.4.5.2.2 pontok előírásait alkalmazzák olyan közleményekre, amelyekben az ICAO három-betűs YXY, YYY vagy ZZZ azonosítóját/azonosítóit két vagy több különböző szervezet (vagy katonai szolgálat) megjelölésére használják, akkor a szövegbe illesztett azonosítók sorrendje meg kell egyezzen a közlemény címzési és feladó részében használt teljes sorrenddel. Ilyen esetben minden címzett-megjelölés után közvetlenül egy kijelölési funkciót kell küldeni. Ilyenkor a közleményt feladó (YXY, YYY vagy ZZZ kóddal jelölt) szervezet neve elé a "FROM" ("...-TÓL") szót kell írni. Az ilyen azonosítók után a szövegrészbe, a szöveg többi részének kezdete elé a "STOP" szót és egy kijelölési funkciót kell írni.

4.4.5.3 A szöveg minden nyomtatott sora után egy kijelölési funkciót [<≡] kell küldeni, kivéve a szöveg utolsó sorát (lásd a 4.4.5.6 pontot).

4.4.5.4 Távgépíró üzemben, ha a szöveg egy részét meg kívánják erősíteni, akkor ezt a megerősítést az utolsó szövegcsoporttól egy kijelölési funkcióval [<≡] kell elválasztani, majd a CFM rövidítéssel kezdve a megerősített szövegrész következik.

4.4.5.5 Távgépíró hálózatban, ha észlelik, hogy a szövegben gépelési hiba történt, akkor a hibajavítást az utolsó szövegcsoporttól, vagy megerősítéstől (ha van ilyen) egy kijelölési funkcióval [<≡] kell elválasztani. Ezután a COR rövidítés és maga a helyesbítés következik.

4.4.5.5.1 A helyi kikézbesítés előtt, az állomás személyzetének el kell végeznie a nyomtatott példányon az összes jelzett helyesbítést.

4.4.5.6 A szöveg végén az alábbi szöveg vége jelet kell küldeni:

Egy BETŰVÁLTÓ [↓], kijelölési funkció [<≡].

4.4.5.7 Az AFTN feladó állomás által begépelt közlemény szövegének hossza nem haladhatja meg az 1800 karaktert.

1. Megjegyzés - Ha a légiforgalmi állandóhelyű távközlési hálózaton keresztül olyan közleményt kívánnak továbbítani, amelynek szövegrész hossza meghaladja az 1800 karaktert, akkor a 4.4.5.7 pont előírásainak értelmében az AFTN feladó állomásnak az ilyen közleményt több közleményre bontva kell feladnia, amely közlemények szövege egyenként sem haladhatja meg az 1800 karakter hosszúságot. A II. kötet "B" melléklete tartalmaz útmutatást arra vonatkozóan, hogyan kell egy hosszú közleményt több különálló közleményre bontani.

2. Megjegyzés - A karakterek számába bele kell számítani minden, a szövegben található nyomtatható és nem nyomtatható karaktert is, a szöveg elejét jelző kijelölő funkciót és a szöveg vége jelet kivéve.

4.4.6 A záró rész

4.4.6.1 A záró résznek az alábbi elemekből kell állnia:
a) lap-emelés jel, vagyis hét darab SOREMELÉS [≡ ≡ ≡ ≡ ≡ ≡ ≡];
Megjegyzés - Ez, valamint az ezt megelőző kijlölési funkcióban található egy SOREMELÉS, már elegendő elkülönítést biztosít a közlemények között, a nyomtatott példányokon.
b) a "közlemény vége" jel, vagyis négy darab "N" betű (a 14-es számú jel betű-készletbeli alakja), megszakítatlan karakter-sorozatként.

Megjegyzés. - Ez az összetevő - amelyet a közlemény első továbbításának pillanatától a végső kézbesítésig mindig sértetlenül továbbítani kell, - azért szükséges, hogy a félautomata vagy teljesen automatikus átjátszó berendezéseken az állomások közötti továbbítás érdekében létrehozott összeköttetéseket fel lehessen szabadítani a további közlemények fogadásához.
Ezt kiegészítőleg, ha a közleményt csak kézi ("tépett szalagos") átjátszó állomásnak adják le:
c) közlemény-elválasztó jel, azaz BETŰVÁLTÓ [↓] tizenkétszer egymás után megszakítatlan karakter-sorozatként.

1. Megjegyzés. - Az egyik közlemény "közlemény vége" jele és a következő közlemény "közlemény eleje" jele között a közlemények továbbítása során csak betűváltó jeleket szabad továbbítani.

2. Megjegyzés. - Az alábbi példa a 4.4.2-től a 4.4.6.1-ig terjedő pontokban leírt eljárások alkalmazását mutatja be, a közlemény nyomtatott példányán:

(Fejrész)	**ZCZC LPA183*
(Cím)	*GG LGGGZRZX LGATKLMW*
(Feladó)	*201838 EGLLKLMW*
(Szöveg)	*Szükség szerint*
(Zárórész)	*(Lapemelés)*
	*NNNN***

**2.A Megjegyzés. - Ha ez a közlemény egy sorozat egyik tagja, és a vevő távgépíró kezelője nem alkalmazott kézi lapemelést az egyes közlemények között, akkor az előző közlemény NNNN jelzése itt jelenik meg.*

***2.B Megjegyzés. - A 2A megjegyzésben leírt körülmények között a következő vett üzenet fejrésze a nyomtatott lapon ezen a helyen íródik ki.*

2.C Megjegyzés. - A gyakorlatban az állomásokon a nyomtatott közleményeket úgy választják el, hogy a lapemelés sorozatnál tépik el a papírt. A "közlemény vége" jel ezért a következő közlemény részévé válik. Nem valószínű azonban, hogy ez a nyilvánvaló áthelyeződés bármilyen félreértést okozna a feladó és a vevő között, hiszen a gyakorlatban a "közlemény vége" jelnek nyomtatott formában nincs jelentősége.

4.4.6.2 Az AFTN feladó állomás által leírt AFTN közlemény hossza nem haladhatja meg a 2100 karaktert.

Megjegyzés.- A karakterek számába bele kell számolni a közleményben található összes nyomtatható és nem nyomtatható karaktert, a beleértve közlemény eleje jelet (ZCZC), és a "közlemény vége" (NNNN) jelet is.

4.4.7 Szalagtovábbítás

4.4.7.1 **Ajánlás.-** *A kézi ("tépett szalagos - torn tape") és a félautomata, folyamatos szalagot használó állomások esetében, ha a 4.4.6.1 pontban leírt jeleken kívül további vezérlő jelekre van szükség annak* *biztosítására, hogy a szalag a vevő állomás újralyukasztó gépéről megfelelően kerüljön tovább, amikor a "közlemény vége" jelet nem követi azonnal a következő közlemény kezdetét jelző jel, akkor lehetőleg a vevő állomáson helyben intézkedjenek annak elkerülése érdekében, hogy ezeket a vezérlőjeleket ne az adó állomásnak kelljen leadnia.*

Megjegyzés. - A kézi ("tépett szalagos") állomásokon általában szükség van olyan berendezésre, amelynek segítségével a szalagot előre lehet mozgatni az újralyukasztó berendezésből, legalább annyira, hogy a kezelő a megfelelő ponton tudja eltépni a szalagot, olyan esetekben, amikor a kezelő már készen áll a szalag eltépésére, de még nem jött következő közlemény, amely a szalagot a berendezésen előre mozgatta volna. A félautomata állomásokon, ahol folyamatos szalaggal dolgoznak, hasonló körülmények között, hasonló eljárásra lehet szükség, hogy a szalagot annyira előre lehessen mozgatni, hogy a "közlemény vége" jel eljusson a leadó berendezésig.

4.4.7.1.1 Ha a 4.4.7.1 pont előírásai nem alkalmazhatók, akkor megállapodást kell kötni a leadó állomással, hogy az, minden egyedülálló közlemény után, vagy egy közlemény-sorozat végén, leadja az előre meghatározott számú BETŰVÁLTÓ jelből [↓] álló sorozatot, a 4.4.6 pontban előírt elemeket kiegészítve.

4.4.8 Rövidített címzés

Amikor a 4.4.3 vagy a 4.4.15.2.1 pont előírásait alkalmazzák, az AFTN távközlő központnak a címzésből ki kell hagynia az összes olyan címzett megjelölését, amely nem szükséges ahhoz, hogy:
a) az AFTN távközlő központ, amelynek elküldték a közleményt, azt tovább tudja küldeni;
b) az AFTN célállomás a közleményt kézbesíteni tudja a címzett(ek)nek;
c) egy több-pontos hálózat esetén az állomás-csoportok a közleményt tovább tudják küldeni, vagy helyben kézbesíteni tudják.

4.4.9 Távgépíró-üzemeltetési eljárások - általános rész

4.4.9.1 *Sor-vége funkciók*

4.4.9.1.1 A nyomtatott példány egy sora összesen legfeljebb 69 karaktert és/vagy szóközt tartalmazhat.

4.4.9.1.2 A közlemény szövegének minden nyomtatott sora után egy "KOCSI-VISSZA" [<] és egy SOREMELÉS [≡] jelet kell továbbítani.

4.4.9.2 *Az adások időtartama.* Szimplex vonalak esetében az egy közleményként leadott közlemény-sorozatok adásideje nem lehet hosszabb kb. öt percnél. A helyesen vett összes közleményt azonnal továbbítani, vagy kézbesíteni kell, anélkül, hogy megvárnák a sorozat végét.

4.4.9.3 *Csatorna-ellenőrző adások.* A 4.4.9.3.3 és a 4.4.9.3.5 pontban leírtak kivételével, a távgépíró vonalakon rendszeres időközönként az alábbi jelsorozatot kell elküldeni:
1) fejrész (lásd 4.4.2.1.1 pontot);
2) kijelölési funkció [<≡];
3) a CH eljárás-jelzés;
4) kijelölési funkció [<≡];
5) a "közlemény vége" jel [NNNN];
6) a közlemény-elválasztó jel [↓↓↓↓↓↓↓↓↓↓↓↓] (ha szükséges).

A vevő állomásnak ekkor ellenőriznie kell ennek a vett adásnak a közlemény-azonosítóját, hogy meggyőződjön arról, hogy annak sorszáma vajon illeszkedik-e az adott bejövő csatornán vett többi közlemény közé.

Megjegyzés.- Ennek az eljárásnak az alkalmazása bizonyos mértékig biztosítani tudja, hogy a csatornán a közlemény-sorszámok folytonossága fennmaradjon.

4.4.9.3.1 **Ajánlás.-** *Ha egy vonalon éppen nincs forgalom, akkor a 4.4.9.3 pontban leírt ellenőrző közleményt adják le lehetőleg minden óra (H) + 00; H + 20, H + 40 perckor.*

4.4.9.3.2 Ha az időszakonként ismétlődő csatorna-ellenőrző adás nem érkezik meg az adott csatorna számára előírt időponthoz képest egy kölcsönösen egyeztetett megengedhető időintervallumon belül, akkor szolgálati közleményt kell küldeni annak az állomásnak, amelytől az ellenőrző adást várták. Ennek a szolgálati közleménynek a szövege a következőkből kell, hogy álljon:

1) az SVC rövidítés;
2) az MIS eljárás-jelzés;
3) a CH eljárás-jelzés;
4) az idő, amikorra az adást várták (választható);
5) az LR eljárás-jelzés;
6) az utolsó vett közlemény azonosítója;
7) a szöveg-vége jel.

Megjegyzés: A következő példa a fenti eljárás alkalmazását mutatja be:
SVC→MIS→CH→[↑1220↓→]LR→ABC↑123↓<≡

4.4.9.3.3 Ha a távgépíró csatorna vezérelt hálózati protokol-rendszer segítségével üzemel, és ha az illetékes Hatóságok között erről kötött megállapodást követik, akkor a 4.4.9.3 pontban leírt adást nem kell elvégezni.

4.4.9.3.4 *Csatorna-ellenőrző adások és az állomás rádió-azonosító*. Annak érdekében, hogy teljesítsék az ITU előírását, amely alapján az állomás rádió-azonosító jelét rendszeres időközönként le kell adni, azok az AFTN állomások, melyek rádió-távgépíró csatornákon dolgoznak, összevonhatják az állomás rádió-azonosító jelének leadását a 4.4.9.3 pontban leírt csatorna-ellenőrző adással. Ebben az esetben a kombinált adást az alábbik szerint kell leadni:

1) fejrész (*lásd* a 4.4.2.1.1 pontot);
2) kijelölési funkció [<≡];
3) a CH eljárás-jelzés;
4) kijelölési funkció [<≡];
5) a DE eljárás-jelzés, egy SZÓKÖZ [→], majd a kiosztott ITU rádió-hívójel;
6) kijelölési funkció [<≡];
7) közlemény-vége jel [NNNN];
8) közlemény-elválasztó jel [↓↓↓↓↓↓↓↓↓↓↓↓] (ha szükséges).

Megjegyzés.- Ennek a formátumnak az alkalmazása teszi lehetővé azt, hogy ezt a speciális adást a teljesen automatikus kapcsoló-központok a felügyelő személyzet beavatkozása nélkül képesek kezelni.

4.4.9.3.4.1 **Ajánlás.-** *Ha több-csatornás rádió-távgépíró vonalakat használnak (pl. MET és AFTN), az állomás rádió-hívójelét lehetőleg csak a vonal egyik csatornáján adják le. Lehetőség szerint azt a csatornát válasszák, amelyik erre a célra a legmegfelelőbb, oly módon, hogy a leadott azonosító adás az adott csatornán használt formátumnak megfelelő legyen. Amikor AFTN csatornát választanak, akkor az azonosító adást ajánlott a csatorna-ellenőrző adással összevonni.*

4.4.9.3.5 Amikor a távgépíró vonalon Automatikus Hiba-javító /Automatic Error Correction (ARQ)/ berendezés működik, és ha az illetékes Hatóságok erről kötött megállapodását követik, akkor a 4.4.9.3 pontban leírt adást nem kell leadni. Azonban, azoknak az állomásoknak be kell tartaniuk a 4.4.9.3.4 pont előírásait, melyek olyan rádió-távgépíró csatornákat használnak az AFTN-en, melyekhez szükség van az állomás rádió-azonosító jelére.

Megjegyzés. - A fentieket nem szabad úgy értelmezni, mintha az ICAO előírná az automatikus *hibajavító (ARQ) berendezések üzembe állítását a nemzetközi légiforgalmi állandóhelyű vonalakon.*

4.4.10 A távgépíró (telex) adások szokásos eljárásai

4.4.10.1 A közleményeket a továbbküldésre vonatkozó, előre meghatározott felelősség szerint kell továbbítani, ahogy abban a közvetlen összeköttetésben lévő állomások üzemeltetéséért felelős Hatóságok kölcsönösen megegyeztek (*lásd* a 4.4.1.3 és a 4.4.1.5.2.3 pontokat is).

4.4.10.1.1 A 4.4.10.1 pontban említett felelősséggel kapcsolatos megállapodásokból következően, az AFTN minden állomásának alkalmaznia kell egy Közlemény-továbbítási Útvonal-Listából (Routing List) álló Közlemény-továbbítási Útvonal Jegyzéket (Routing Directory), melytől a 4.4.10.1.1.1 pont előírásai szerint nem térhet el.

4.4.10.1.1.1 Ha egy bejövő közlemény a fejrész után következő sorokban csak azonos helység jelöléseket tartalmaz, akkor a vevő állomásnak magára vállalnia a közlemény tovább-küldésének felelősségét. Ha lehetséges, a közlemény ilyen tovább-küldését a célállomására a szokásos kimenő vonalon kell végrehajtani; ha ez a vonal nem alkalmazható, akkor megfelelő alternatív kimenő vonalat kell használni. Ha ezen eszközök közül egyik sem működik, akkor a közleményt nem lehet visszaküldeni azon a vonalon, amelyen kapták, csak ha előtte egy szolgálati közleményben (lásd a 4.4.1.1.9 pontot) értesítik erről a megelőző adást lebonyolító állomást.

4.4.10.1.1.2 **Ajánlás. -** *Amennyiben az AFTN közlemény feladója nem képes a szolgálati közleményeket kezelni, lehetőség szerint egyezzen meg a vele összeköttetésben lévő AFTN központtal, hogy milyen módszerrel kezeljék az egymás közötti szolgálati közleményeket.*

Megjegyzés.- A 4.4.4.4.2 és a 4.4.4.4.2.1 pontban egy, a szolgálati címzés szabadon választható adatmezőben történő meghatározására szolgáló módszer található.

4.4.10.1.2 *Az adás formája - távgépíró üzem.* Minden adásnak az alábbi sorrendben kell felépülnie (*lásd* a 4-2. ábrát).

4.4.10.1.2.1 *Kezdő impulzus*. Ha a vevő állomás időkapcsolóval felszerelt berendezést használ, amely leállítja a távgépíró készülék motorját, amikor a csatornán nincs forgalom, akkor egy 20-30 milliszekundumos SZÜNET /SPACING/ IMPULZUST kell küldeni, ha a csatornán már legalább 30 másodpercig nem volt adás, majd ezután legalább 1,5 másodperc szünetet kell hagyni a fejrész leadásának megkezdése előtt.

1. Megjegyzés. - Ez megfelel egy BETŰVÁLTÓ [↓] *jel és egy legalább 1,37 másodperces szünet (vagyis egy folyamatos JELZÉS IMPULZUS /Marking Impulse/) elküldésének.*

2. Megjegyzés. - Ennek az eljárásnak az alkalmazása lehetővé teszi, hogy a vevő berendezés szinkronba kerülhessen, mielőtt a vonalon a fejrész továbbítása megkezdődik.

4.4.10.1.3 *Közlemény-formátum.* Minden közleményt a 4.4.2 pont előírásai (ITA-2 formátum), vagy a 4.4.15 pont előírásai (IA-5 formátum) szerint kell összeállítani.

KEZDŐ IMPULZUS *(ha szükséges)*		FEJRÉSZ	CÍMZÉS	FELADÓ	SZÖVEG	ZÁRÓRÉSZ

4-2. ábra: Az adás formája - távgépíró üzemben (lásd a 4.4.10.1.2 pontot)

4.4.10.1.3.1 **Ajánlás. -** *Az Annex 10, III. kötetének 8.6.3 és 8.6.4 pontjaiban leírt adatkapcsolati protokol eljárásokat alkalmazó vonalakon a Fejrész Sort - az SOH karakter kivételével - lehetőleg el kell hagyni.*

4.4.10.1.4 *Újra-feldolgozási eljárások*

4.4.10.1.4.1 Ha egy közleményt újra fel kell adni, akkor az az állomás, amelyik a közleményt továbbításra megkapta, a közlemény előző fejrészét törli. Az újbóli adás az új fejrésszel kezdődik, a kimenő csatornának megfelelő közlemény-továbbítási azonosítóval.

4.4.10.1.4.1.1 Amikor a 4.4.10.1.4.1 pont előírásait alkalmazzák, a közlemény cím-részének adását valamikor az első kijelölési funkciót [<≡] közvetlenül megelőző 5 SZÓKÖZ-ből, egy BETŰVÁLTÓ-ból álló [→→→→→↓] jelsorozat idején kell megkezdeni.

4.4.10.1.4.1.2 Az alárendelt és a kézi ("tépett szalagos") átjátszó állomásokon, amelyek nincsenek automatikus közlemény-sorszámot előállító berendezésekkel felszerelve, és ahol ezért szükséges a szalagra néhány további távgépíró-karaktert lyukasztani a közlemény-eleje jelzés elé, azért, hogy ez a jelzés ne sérüljön a további feladáskor, az ilyen további karaktereknek BETŰVÁLTÓ [↓] jeleknek kell lenniük. Ezután a tovább-küldéskor a kimenő csatornán az adást a közlemény-eleje jelhez minél közelebb kell megkezdeni, amennyire ez gyakorlatilag lehetséges.

4.4.10.1.4.1.3 Olyan állomásokon, ahol a közlemény fejrészét automatikus berendezés állítja elő, azon a ponton és akkor, amikor az adás a kimenő csatornán megtörténik, de a közlemény többi részét szalag-lyukasztással készítik el, és ezért szükséges, hogy a címzés kezdetén lévő kijelölési funkció [<≡] elé a szalagra néhány további távgépíró-karaktert lyukasszanak, hogy eleve kizárja a kijelölési funkció sérülését, az ilyen kiegészítő karaktereknek BETŰVÁLTÓ [↓] jeleknek , vagy SZÓKÖZ-öknek [→] kell lenniük. Ezután a tovább-küldéskor a kimenő csatornán az adást a közlemény első kijelölési funkciójához [<≡] minél közelebb kell megkezdeni, amennyire ez gyakorlatilag lehetséges.

4.4.10.1.4.2 A kézi ("tépett szalagos") átjátszó állomásokon a kapott szalagokat a közlemény-elválasztó jelben kell eltépni (*lásd* a 4.4.6.1 és a 4.4.7.1 pontokat), úgy, hogy az előző "közlemény-vége" jel sértetlen maradjon.

4.4.10.1.4.2.1 A 4.4.10.1.4.2 pont előírásainak alkalmazása után a szalagon maradt, megrövidült (vagyis, 12 BETŰ- VÁLTÓ [↓] jelnél rövidebb) közlemény-elválasztó jelet törölni kell, ha szükséges, elektronikus eszközökkel, mielőtt a közleményt újra feladják egy automatikus átjátszó állomásnak. Ha a közleményt egy másik kézi ("tépett szalagos") átjátszó állomásnak kell újra feladni, akkor:
1) a megrövidült közlemény-elválasztó jelet ki kell egészíteni egy teljes elválasztó jelzéssé [↓↓↓↓↓↓↓↓↓↓↓↓] (azaz 12 db [↓]) a szükséges számú további BETŰVÁLTÓ [↓] jel leadásával; vagy
2) a szalagon maradt, megrövidült közlemény-elválasztó jelzést el kell távolítani, és egy új, teljes közlemény-elválasztó jelet kell helyette betenni az újra-feldolgozás folyamán, a 4.4.6.1 c) pont előírásainak megfelelően.

4.4.10.1.5 A kézi ("tépett szalagos"), vagy félautomata állomásokon, ha csak lehetséges, tovább-küldés előtt egy hibátlan szalagpéldányt kell beszerezni. Ha a szalag olvashatatlan, vagy sérült, akkor az állomás nem küldheti tovább a közleményt, kivéve, ha józan megfontolás alapján ez valószínűleg nem okoz hibát a következő átjátszó állomások berendezéseinek működésében.

4.4.10.1.6 *A közlemények vételének nyugtázása.* Távgépíró-üzemben, a 4.4.10.1.6.1 pontban leírt eset kivételével, a vevő-állomásnak nem kell a bejövő üzenetek vételét igazoló nyugtázó közleményt küldenie. Ehelyett a 4.4.1.4.1 pont előírásait kell alkalmazni.

4.4.10.1.6.1 Vészhelyzeti közlemények (SS elsőbbségi jelzéssel - *lásd* a 4.4.1.1.1 pontot) vételét az AFTN célállomásnak egyedileg nyugtáznia kell, egy szolgálati közlemény (*lásd* a 4.4.1.1.9 pontot) küldésével, a feladó AFTN állomásnak. A vétel ilyen nyugtázását teljes közlemény formájában kell kiadni, amelyet a közleményt feladó AFTN állomásnak címeznek, és az SS elsőbbségi jelzéssel kell ellátni és az ehhez kapcsolódó elsőbbségi figyelemfelhívó jelzéssel (lásd a 4.4.4.3 pontot). A közlemény szövegének az alábbiakat kell mgába foglalnia:

1) az R eljárás-jelzés;

2) a nyugtázott közlemény feladója (lásd a 4.4.4 pontot), az elsőbbségi figyelem-felhívó jelzés, vagy választható fejrész adatok nélkül;

3) a szöveg-vége jel [↓<≡]

Megjegyzés. - A következőpélda a 4.4.10.1.6.1 pontban leírt eljárás alkalmazását mutatja be:

Fej-rész (lásd a *4.4.2.1.1* pontot)

<≡SS→LECBZRZX<≡

↑121322↓→EGLLYFYX (elsőbbségi figyelemfelhívó jelzés) <≡

R→↑121319↓→LECBZRZX↓<≡

Záró rész (lásd a *4.4.6* pontot)

4.4.10.1.7 Abban az esetben, ha egy több címzettel rendelkező közlemény egyik címzettje a közlemény ismétlését kéri a feladó állomástól, a feladó állomás csak az ismétlést kérő címzettnek fogja megcímezni az ismételten leadott közleményt. Ilyen körülmények között a DUPE eljárás-jelet nem kell befoglalni.

4.4.11 Intézkedések abban az esetben, ha a távgépíró átjátszó állomás sérült, vagy rosszul formázott közleményt talál.

4.4.11.1 Ha egy átjátszó állomás még az újra-feladás megkezdése előtt észleli, hogy egy közlemény a "közlemény- vége" jel előtt valamelyik ponton megsérült, vagy rosszul formázták, és jó oka van azt hinni, hogy a sérülés még az előtt következett be, hogy az előző állomás a közleményt megkapta, akkor szolgálati közleményt (*lásd* a 4.4.1.1.9 pontot) kell küldenie annak a feladónak, akit a sérült vagy rosszul formázott közlemény feladó-megjelölése azonosít, és ebben a szolgálati közleményben a hibásan vett közlemény ismétlését kell kérnie.

1. Megjegyzés. - A következő példa bemutatja egy, a fenti eljárás szerint összeállított szolgálati közlemény szokásos szövegét, amelyben egy olyan sérült közlemény ismétlését kéri, amelynek feladó része "141335 CYULACAX" volt:
SVC→QTA→RPT→141335→↑CYULACAX↓<≡

2. Megjegyzés. - A sérülés észlelése általában csak a kézi ("tépett szalagos" /"torn tape"/) átjátszó állomásokon lehetséges.

4.4.11.2 Amikor a 4.4.11.1 pont előírásait alkalmazzák, a sérült közlemény feladó részében azonosított feladó vissza kell, hogy vegye a felelősséget a sérült közleményért, és a 4.4.11.3 pont előírásait köteles teljesíteni.

4.4.11.3 A 4.4.11.2 pont előírásainak alkalmazása után a következő újra-feldolgozást kell elvégezni, mielőtt a közlemény hibátlan változatát másodjára is feladják ugyanannak a címzettnek vagy címzetteknek:
1) új fejrész *beillesztése*;

2) a közlemény záró részének *eltávolítása* (*lásd* a 4.4.6.1 pontot);
3) ehelyett a DUPE eljárás-jelzés *beillesztése*, amely elé legalább egy BETŰVÁLTÓ [↓] jelet, utána pedig 1 db KOCSI VISSZA és 8 db SOREMELÉS jelet kell tenni, majd következnek a “közlemény-vége” jel, és amennyiben szükséges (*lásd* a 4.4.6 és a 4.4.7 pontokat), a közlemény-elválasztó jelzés és a szalag-továbbítás BETŰVÁLTÓ [↓] jelei.

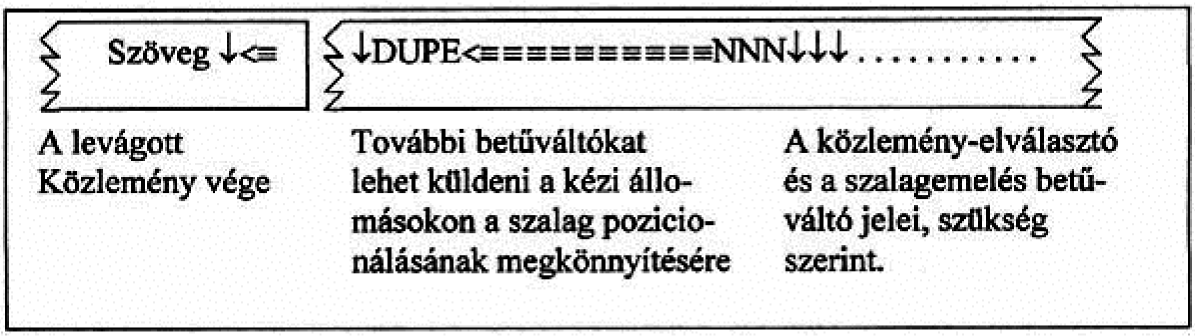
Megjegyzés.- A 4-3. ábrán látható példa bemutatja ennek az eljárásnak az alkalmazását.

4.4.11.4 Ha egy átjátszó állomás még az újra-feladás megkezdése előtt észreveszi, hogy egy vagy több közlemény - még a “közlemény-vége” jel előtt valamelyik ponton - megsérült, és jó oka van azt hinni, hogy a sérülés az előző állomástól neki történő tovább-küldés során vagy az után történt, akkor szolgálati közleményt (*lásd* a 4.4.1.1.9 pontot) kell küldenie az előző állomásnak, amelyben visszautasítja a sérült közlemény vételét, és a hibás közlemény (vagy közlemények) ismétlését kéri.

1. Megjegyzés. - A következő példa a fenti eljárás alkalmazását mutatja be. A 2)*-ként jelzett példában a kötőjel (-) elválasztót nyílt szövegben "valamennyitől - valameddig"-nek kell értelmezni.*

1) *csak egy közlemény sérülése esetén:*
SVC→QTA→RPT→ABC↑123↓<≡

2) *több közlemény sérülése esetén:*
SVC→QTA→RPT→ABC↑123-126↓<≡



4-3. ábra: Példa a 4.4.11.3 pontban leírt eljárás alkalmazására.

2. Megjegyzés. - A sérülés észlelése általában csak a "tépett-szalagos" átjátszó állomásokon lehetséges.

4.4.11.5 Amikor a 4.4.11.4 pont előírásait alkalmazzák, akkor annak az állomásnak, amelyik veszi a szolgálati közleményt, vissza kell vennie a felelősséget a hivatkozott közleményért. Ezután köteles a hivatkozott közlemény sérülésmentes másolatát ismételten továbbítani egy új (azaz megfelelően sorszámozott) közlemény azonosítóval (*lásd* a 4.4.2.1.1 b) pontot). Ha ez az állomás nincs birtokában az eredeti közlemény sérülésmentes változatának, akkor a 4.4.11.1 pontban leírtak szerint kell, hogy eljárjon.

4.4.11.6 Ha mielőtt az újra-feladás megkezdődne, az átjátszó állomás észleli, hogy a vett közlemény rendelkezik felismerhető "közlemény-vége jellel", de az megsérült, akkor az állomás, ha szükséges, köteles kijavítani ezt a sérülést mielőtt a közleményt továbbítaná.

Megjegyzés. - A sérülés észlelésének ilyen körülményei általában csak a kézi ("tépett szalagos" /"torn tape"/) átjátszó állomásokon lehetségesek, és a leírt eljárás azokban az esetekben lehet alapvető fontosságú, amikor a közleményeket félautomata vagy teljesen automatikus állomások felé továbbították.

4.4.11.7 Ha egy átjátszó állomás egy közlemény újra-feladása közben észreveszi, hogy a közlemény - még a "közlemény-vége jel" előtt - valamely ponton megsérült, és még van ideje intézkedni, mielőtt a pontos "közlemény-vége jelet" leadná, akkor
1) törölnie kell a közleményt úgy, hogy a csatornára a ↓<≡QTA→QTA↓<≡ jelsorozatot adja le, amelyet teljes záró rész követ (*lásd* a 4.4.6 pontot);
2) visszaveszi a közleményért a felelősséget;
3) teljesíti a 4.4.11.1, vagy a 4.4.11.4 pont előírásait, amelyik a megfelelő.

Megjegyzés. - A sérülés észlelésének ilyen körülményei általában csak a kézi ("tépett szalagos") átjátszó állomásokon lehetségesek, vagy félautomata állomásokon, melyek folyamatos szalagot használnak.

4.4.11.8 Ha egy állomás egy közlemény teljes egészében történő leadása után veszi észre, hogy a közlemény szöveg-, vagy feladó része sérült, vagy hiányos, és ha a közlemény hibátlan példánya a rendelkezésére áll, akkor valamennyi érintett címzettnek szolgálati közleményt kell küldjön, az alábbi szöveggel:

SVC CORRECTION *(a hibás közlemény feladó része)*
STOP *(majd a helyes szöveg).*

Megjegyzés. - A sérülés észlelésének ilyen körülményei általában csak a kézi ("tépett szalagos") átjátszó állomásokon lehetségesek, vagy félautomata állomásokon, melyek folyamatos szalagot használnak.

4.4.11.9 Amikor egy átjátszó állomás a közlemény szöveg-részének leadása után veszi észre, hogy a közleménynek nyilvánvalóan sérült "közlemény-vége" jelzése van, akkor szabályos "közlemény-vége" jelet kell, hogy beillesszen és leadjon a csatornán.

Megjegyzés. - A sérülés észlelésének ilyen körülményei általában csak a kézi ("tépett szalagos") átjátszó állomásokon lehetségesek, vagy félautomata állomásokon, melyek folyamatos szalagot használnak.

4.4.11.10 Ha egy átjátszó állomás egy közlemény szöveg-részének leadása után észreveszi, hogy a közleménynek nincs teljes "közlemény-vége" jelzése, de gyakorlatilag nincs lehetősége kideríteni, hogy a hiba csak a "közlemény-vége" jelzésben jelentkezett, vagy az eredeti szöveg egy része is elveszett, akkor a csatornán a következő jelsorozatot adja le:
1) ↓<≡CHECK≡TEXT≡
NEW→ENDING→ADDED→
2) a saját állomás-azonosítója;
3) ↓<≡
4) szabályos záró rész, a 4.4.6.1 pont előírásai szerint.

1. Megjegyzés. - A szalagos példányon ez a beszúrás a következőképpen jelenik meg:
↓<≡CHECK≡TEXT≡
NEW→ENDING→ADDED→LOWWYFYX↓<≡
≡≡≡≡≡≡≡NNNN↓↓↓ . . .

2. Megjegyzés. - A nyomtatott példányon ez a beszúrás a következőképpen jelenik meg:
CHECK
TEXT
NEW ENDING ADDED LOWWYFYX
NNNN

3. Megjegyzés. - A nyomtatott példány lépcsőzetes írásmódjának célja az, hogy azonnal felhívja a címzett figyelmét a beszúrásra.

4. Megjegyzés. - SZÁMVÁLTÓ [↑] *beszúrása biztosítja a helyes működést ott, ahol Első Sor Figyelő Készülékkel (First Line Monitoring Equipment) dolgoznak, ahol a feladó részben előforduló SZÁMVÁLTÓ jelet használják ezen berendezés lekapcsolására, és ahol a közlemény hiányzó része tartalmazza ezt a SZÁMVÁLTÓ jelet.*

5. Megjegyzés. - A sérülés észlelése általában csak a teljesen automatikus, vagy a folyamatos szalag nélkül dolgozó félautomata állomások számára lehet fontos.

4.4.11.11 **Ajánlás. -** *Ha egy átjátszó állomás a 4.4.11.9 vagy a 4.4.11.10 pontban leírt eljárásokat alkalmazza, akkor - amennyire ez gyakorlatilag lehetséges - gondoskodjon róla, hogy az abban meghatározott jelsorozatokat még bármely későbbi közlemény teljes "közlemény- kezdete" jelzése előtt leadja.*

4.4.11.12 Ha egy átjátszó állomás észreveszi, hogy olyan közleményt kapott, amelynek címzés-sora teljesen sérült, akkor szolgálati közleményt kell küldenie a megelőző állomásnak, amelyben visszatasítja a sérült közlemény vételét.

4.4.11.12.1 Ennek a szolgálati közleménynek a szövege a következő:
1) az SVC rövidítés;
2) a QTA eljárás-jelzés;
3) az ADS eljárás-jelzés;
4) a visszautasított közlemény azonosítója;
5) a CORRUPT szó;
6) a szöveg-vége jel.

Megjegyzés. - A következő példa a fenti eljárás alkalmazását mutatja be:
SVC→QTA→ADS→ABC↑123↓→CORRUPT↓<≡

4.4.11.12.2 Annak az állomásnak, amelyik ilyen szolgálati közleményt vett, újra el kell vállalnia a felelősséget az említett közleményért, és ismét fel kell adnia a közleményt a helyesbített címzéssel és az új közlemény-azonosítóval.

4.4.11.13 Ha egy átjátszó állomás észreveszi, hogy egy vett közlemény címzett megjelölése érvénytelen (vagyis nem 8 karakter hosszú), vagy a címzett megjelölése ismeretlen, akkor a közleményt tovább kell küldenie azokra az érvényes címekre, amelyek felé neki tovább-küldési felelőssége van, a rövidített címzési eljárást alkalmazva (*lásd* a 4.4.8 pontot).

4.4.11.13.1 Ezenkívül - a 4.4.11.13.3 pontban leírt eset kivételével - az állomás szolgálati közleményt kell, hogy küldjön az előző állomásnak, amelyben a hiba kijavítását kéri. Ennek a szolgálati közleménynek a szövege az alábbiakból álljon:

1) az SVC rövidítés;
2) az ADS eljárás-jelzés;
3) a hibás közlemény azonosítója;
4) egy kijelölési funkció;
5) a vett közlemény első címsora, ahogy vette;
6) egy kijelölési funkció;
7) vagy a
   a) CHECK szó, ha a közlemény címzett megjelölése érvénytelen volt; vagy az
   b) UNKNOWN szó, ha a közlemény címzett megjelölése ismeretlen volt;

8) az érvénytelen, vagy ismeretlen címzett megjelölés(ek);
9) a szöveg-vége jel.

Megjegyzés: A következő példák a 4.4.11.13.1 pontban leírt eljárás alkalmazását mutatják be:
a) érvénytelen címzett-megjelölés esetén:
SVC→ADS→ABC↑123↓<≡
GG→EGLLACAX→EPKYTYX→CYAAYFYX→
CYQXAFX<≡CHECK→CYQXAFX↓<≡
b) ismeretlen címzett-megjelölés esetén:
SVC→ADS→ABC↑123↓<≡
GG→EGLLACAX→EGEHYTYX→CYAAYFYX→
CYQXACAX<≡UNKNOWN→EGEHYTYX↓<≡

4.4.11.13.2 A 4.4.11.13.1 pontban leírt szolgálati közleményt vevő állomás - amennyiben a helyes címzés rendelkezésére áll - megismétli a közleményt csak annak a bizonyos címzettnek a részére, a rövidített címzési eljárás alkalmazásával (*lásd* a 4.4.8 pontot), vagy ha a helyes címzés nem áll a rendelkezésére, akkor a 4.4.11.13.1 pontban leírt eljárás szerint jár el.

4.4.11.13.3 Ha a 4.4.11.13 pontban leírt eljárást alkalmazzák ismeretlen címzett esetén, és ha a közlemény feladó részében nincs hiba, akkor az állomás szolgálati közleményt kell, hogy küldjön a feladó részére. Ennek a szolgálati közleménynek a szövege tartalmazza az alábbiakat:

1) az SVC rövidítést;
2) az ADS eljárás-jelzést;
3) a hibás közlemény feladó részét;
4) egy kijelölési funkciót;
5) a vett közlemény első címsorát, ahogy vette;
6) egy kijelölési funkciót;
7) az UNKNOWN /ISMERETLEN/ jelölést;
8) az ismeretlen címzett(ek) megjelölését;
9) a szöveg-vége jelet.

Megjegyzés. - A következő példa a fenti eljárás alkalmazását mutatja be:
SVC→ADS→↑141335↓→CYULACAX<≡
GG→EGLLACAX→EGEHYTYX→CYAAYFYX→
CYQXACAX<≡UNKNOWN→EGEHYTYX↓<≡

4.4.11.13.4 Az ilyen szolgálati közleményt vevő állomásnak be kell szereznie a címzett pontos megjelölését, és meg kell ismételnie a közleményt a címzettnek, a rövidített címzési eljárás alkalmazásával (*lásd* a 4.4.8 pontot).

4.4.11.14 Ha az első átjátszó állomás észreveszi azt, hogy olyan közleményt kapott, amelynek a feladó sora sérült, vagy a feladó megjelölése teljesen hiányzik, akkor:
a) abbahagyja a közlemény feldolgozását;
b) szolgálati közleményt küld annak az állomásnak, amelyiktől a közleményt kapta.

4.4.11.14.1 Ennek a szolgálati közleménynek a szövege a következőket kell, hogy magába foglalja:
1) az SVC rövidítést;
2) a QTA eljárás-jelzést;
3) az OGN eljárás-jelzést;
4) a visszautasított közlemény azonosítóját;
5) a CORRUPT megjelölést;
6) a szöveg-vége jelet.

Megjegyzés. - A következő példa a fenti eljárás alkalmazását mutatja be:
SVC→QTA→OGN→ABC↑123↓→CORRUPT↓<≡

4.4.11.14.2 A 4.4.11.14.1 pontban leírt szolgálati közleményt vevő állomásnak az említett közleményért vissza kell vennie a felelősséget, és ismét fel kell, hogy adja a közleményt a hibátlan feladó résszel és új közlemény azonosítóval.

Megjegyzés. - Amikor a 4.4.11.14 pont előírásait alkalmazzák, az AFTN közlemények feladó része feldolgozá- sának minimális követelményei az alábbiak:
1) a dátum-idő csoport hat számjegyből kell, hogy álljon;
2) a feladó megjelölésének nyolc betűből kell állnia.

4.4.11.15 Ha az első átjátszó állomás észreveszi, hogy egy közleményt rossz feladó- megjelöléssel vettek, akkor az alábbiakat kell végrehajtania:
a) abbahagyja a közlemény feldolgozását; és
b) szolgálati közleményt küld annak az állomásnak, amelytől a közleményt vette.

4.4.11.15.1 Ezen szolgálati közlemény szövegének tartalmaznia kell:
1) az SVC rövidítést;
2) a QTA eljárás-jelzést;
3) az OGN eljárás-jelzés;
4) a visszautasított közlemény azonosítóját;
5) az INCORRECT jelzést; és
6) a szöveg-vége jelet.

Megjegyzés. - Az alábbi ITA-2 példa a fenti eljárás alkalmazását mutatja be:
SVC→QTA→OGN→ABC↑123↓→INCORRECT↓<≡

4.4.11.15.2 Egy, a 4.4.11.15.1 pontban leírt szolgálati közleményt vevő állomásnak vissza kell vennie a felelősséget az említett közleményért, ismét fel kell adnia a közleményt egy pontos feladó megjelöléssel és - ha megfelelő - egy új közlemény-azonosítóval.

Megjegyzés. - Amikor a 4.4.11.15 pont előírásait alkalmazzák, akkor a közvetítő állomás követelménye az, hogy minimumként a feladó megjelölésének első karakterét ellenőrizzék, mivel a helység jelölés első karaktere az a hely, amelynek a közleményt feladaták.

4.4.12 A szalagok előkészítése során elkövetett hibák javítása

4.4.12.1 Az olyan közlemények, amelyeknek szalagját a feladó állomáson készítik elő, ismert, kijavítatlan hibákkal nem kerülhetnek be az AFTN hálózatba.

4.4.12.2 Ha a hibát még a közlemény szöveg-része előtt követik el, akkor a javítást úgy kell elvégezni, hogy a hibás szalagot eldobják, majd újat készítenek helyette.

4.4.12.3 Ha csak lehetséges, a közlemény szöveg-részében elkövetett hibákat úgy kell kijavítani, hogy a szalagot visszaléptetik és a nem kívánt részt a BETŰVÁLTÓ jellel [↓] felülírják.

4.4.12.4 Ahol a 4.4.12.3 pontban leírt eljárás nem lehetséges, ott a szöveget úgy kell javítani, hogy közvetlenül a hiba után az [→E→E→E→] hibajelzést írják, majd leírják az utolsó helyes szót vagy szócsoportot, és aztán folytatják a szalag írását.

4.4.12.5 Ha sem a 4.4.12.3, sem a 4.4.12.4 pontban leírt eljárás nem alkalmazható, mert a szövegben elkövetett hibát csak a lyukasztási folyamat későbbi szakaszában veszik észre (de még a "közlemény-vége" jel hozzáadása előtt), akkor az állomásnak a 4.4.5.5 pontban leírtak szerint kell eljárnia.

4.4.12.6 A záró résznek hibátlannak kell lennie.

4.4.13 A közlemény feladása során elkövetett hibák javítása, ha a közlemény már a készítés közben bekerül az AFTN hálózatba

4.4.13.1 Ha a közlemény már a készítés során bekerül az AFTN hálózatba, nem szabad a közleményt "közlemény vége" jellel lezárni, ha az ismert, kijavítatlan hibákat tartalmaz.

4.4.13.2 Ha ilyen körülmények között hibát követnek el a közleményben még a szöveg-rész előtt bárhol, akkor a befejezetlen közleményt törölni kell a ↓<≡QTA→QTA↓<≡ jelsorozat leadásával, amelyet egy teljes záró rész követ (*lásd* a 4.4.6 pontot).

4.4.13.3 A szövegben elkövetett, és azonnal észrevett hibákat úgy kell javítani, hogy beírják az [→E→E→E→] hibajelzést, majd az utolsó helyes szót vagy szócsoportot, aztán folytatják a közlemény beírását.

4.4.13.4 Abban az esetben, ha a szövegben elkövetett hibát csak a feladás későbbi szakaszában veszik észre, akkor az állomásnak a 4.4.5.5 pontban leírt előírások szerint kell eljárnia.

4.4.13.5 Abban az esetben, ha a szöveg feladása során nyilvánvalóvá válik, hogy a közleményt törölni kellene, akkor az állomásnak a 4.4.13.2 pontban leírt előírások szerint kell eljárnia.

4.4.14 AFTN közlemények előre meghatározott szétosztási rendszere

4.4.14.1 Ha az érintett Hatóságok (kormányzati szervek) az AFTN közlemények számára előre meghatározott szétosztási rendszer alkalmazásában állapodnak meg, akkor az alábbiakban meghatározott rendszert kell alkalmazni.

4.4.14.2 Az Előre Meghatározott Szétosztási Címzett Kijelölést (PDAI /Predetermined Distribution Addressee Indicator/) a következőképpen kell összeállítani:
a) Az első és második betű:
Azon Állam távközlő központja Helységnév Azonosítójának első két betűje, mely állam hozzájárult a rendszer bevezetéséhez, és amely egy olyan hálózaton keresztül kapja a közleményeket, amely számára előre meghatározott továbbítási útvonal-kiválasztási felelőssége van;
b) A harmadik és negyedik betű:
A ZZ betűk, a speciális szétosztás szükségességének jelzésére;
c) A hatodik, hetedik és nyolcadik betű:
1) Az A-tól Z-ig terjedő sorozatból kiválasztott hatodik, hetedik és nyolcadik betű, amely azt az országos és/vagy nemzetközi szétosztási listá(ka)t jelöli meg, amelye(ke)t a vevő AFTN központnak kell használnia;
2) Az ötödik betű helyén az "N" és "S" betűket értelemszerűen a NOTAM illetve a SNOWTAM megjelölésére tartják fönn (*lásd* az Annex 15 5. Függelékét);
d) A nyolcadik betű:

Vagy a helykitöltő "X" betű, vagy az A-tól Z-ig terjedő sorozat egy betűje, amely további azonosításként szolgál az országos és/vagy nemzetközi szétosztási listá(k) megjelölésére, melye(ke)t az átvevő AFTN központnak kell használnia.

1. Megjegyzés. - Annak érdekében, hogy elkerüljék az AFTN "közlemény-eleje" jelzéssel az összetévesztés lehetőségét, a "ZC" vagy "CZ" betűkombinációk nem használhatók.

2. Megjegyzés. - Azért, hogy elkerüljék az AFTN "közlemény-vége" jelzéssel történő összetévesztés lehetőségét, az "NN" betűkombináció nem használható.

4.4.14.3 **PANS** (Légiforgalmi Szolgálatok Eljárásai)**. -** *Az Előre Meghatározott Szétosztási Címzett Kijelöléseket (PDAIs /Predetermined Distribution Addressee Indicators/) - ha csak lehetséges - használni kell az azon Államok között küldött AFTN közleményekben, amelyek megállapodtak az előre meghatározott szétosztási rendszer használatában.*

4.4.14.4 Azokat az AFTN közleményeket, amelyek a vevő Állam által kiosztott PDAI (Előre Meghatározott Szétosztási Címzett Kijelölés) megjelöléseivel rendelkeznek, a 4.4.14.5 pontban leírt kapcsolódó címzett-listán felsorolt címzettekhez kell irányítani.

4.4.14.5 Az Államok a kiválasztott PDAI megjelöléseket és a hozzájuk tartozó címzett megjelölések listáit meg kell, hogy küldjék a következők részére::
a) azoknak az Államoknak, amelyektől AFTN közleményeket kapnak előre meghatározott körű szétosztásra, hogy a helyes továbbítási útvonal-kiválasztást biztosíthassák; és
b) azoknak az Államoknak, amelyek AFTN közleményeket állítanak össze előre meghatározott körű szétosztásra, hogy megkönnyítsék az újra-feladási kérelmek kezelését és segítsék a feladókat a PDAI megjelölések helyes használatában.

4.4.14.5.1 Egy PDAI-hez tartozó címzett megjelölések listájában az alábbi elemeknek kell szerepelni:
a) címzett megjelölések nemzeti szétosztásra; vagy
b) címzett megjelölések nemzetközi szétosztásra; vagy
c) PDAI megjelölések nemzetközi szétosztásra; vagy
d) az a), b) és c) elemek bármely kombinációja.

4.4.15 Közlemények formátuma - 5-ös számú Nemzetközi ABC (IA-5)

Ha az érintett Hatóságok az 5-ös számú Nemzetközi (IA-5) ABC használatában állapodtak meg, akkor a 4.4.15-től a 4.4.15.3-ig terjedő pontokban leírt közlemény-formátumot kell használniuk. Az IA-5-öt használó Hatóságok felelőssége annak biztosítása, hogy alkalmazkodjanak azokhoz a szomszédos AFTN állomásokhoz, amelyek a 4.4.2 pontban leírt formátumú ITA-2 kódot használják.

Minden közleményt - a 4.4.1.8 és a 4.4.9.3 pontban leírtak kivételével - a 4.4.15.1-től a 4.4.15.6-ig terjedő pontokban leírt elemekből kell összeállítani.

1. Megjegyzés. - A 4-4. ábra mutatja be az IA-5 közlemény-formátumot.

2. Megjegyzés. - Az alább részletezett, a közlemény-formátumra vonatkozó szabványokban a következő szimbólumokat használtuk az IA-5 bizonyos jeleihez rendelt funkciók megjelölésére. (Lásd a III. Kötet, I. Rész, 8.6.1 pontját, valamint a 8-2. és 8-3. Táblázatokat.)

Jel	*Jelentés*
<	KOCSI VISSZA (a 0/13 karakter pozíció)
≡	SOREMELÉS (a 0/10 karakter pozíció)
→	SZÓKÖZ (a 2/0 karakter pozíció)

4.4.15.1 *Fej-rész*

4.4.15.1.1. A fej-rész az alábbi elemekből kell , hogyálljon:
a) fej-rész - kezdete jel (SOH), a 0/1 karakter;
b) közlemény-azonosító, amelynek az elemei:
1) az áramkör vagy vonal azonosítója;
2) csatorna-sorszám;
c) további szolgálati információk (ha szükséges), amelynek elemei:
1) egy SZÓKÖZ;

2) és legfeljebb 10 karakter.

4.4.15.1.1.1 A pont-pont közötti áramkörök vagy vonalak esetén az azonosító az adó-állomás által kiválasztott és hozzárendelt három betűből áll; az első betű a vonal adó felőli végét, a második a vevő felőli végét, a harmadik pedig a csatornát azonosítja. Ha csak egy csatorna létezik, akkor az " A" betűt kell használni. Ha az állomások között több csatorna is van, akkor a csatornákat sorrendben az “A”, “B”, “C”, stb. betűkkel kell azonosítani. Több-pontú csatornák esetében az azonosító a vonalat ellenőrző vagy vezérlő (“master”) állomás által kiválasztott és hozzárendelt három betűből áll.

4.4.15.1.1.2 A 4.4.15.1.1.3 pontban leírtak kivételével, a távközlési állomásoknak minden, közvetlenül az egyik állomástól a másikhoz küldött közleménynek háromjegyű csatorna-sorszámot kell kijelölniük, amely 001-től 000-ig (mely 1000-et jelent) terjed. Minden csatornán külön kell a közleményeket sorszámozni, és minden nap 0000 órakor új számsorozatot kell kezdeni.

4.4.15.1.1.3 **Ajánlás. -** *Annak érdekében, hogy elkerülhető legyen ugyanazon sorszámok ismételt előfordulása 24 órán belül, lehetőleg meg kell engedni a csatorna-sorszámok bővítését, ha erről a vonal üzemeltetéséért felelős Hatóságok megállapodást kötöttek.*

4.4.15.1.1.4 A közlemény-azonosítót a vonalon az alábbi sorrendben kell leadni:
a) az adó-terminál betűjele;
b) a vevő-terminál betűjele;
c) csatorna-azonosító betű;
d) a csatorna-sorszám.

4.4.15.1.1.5 Meg kell engedni további szolgálati tájékoztatás beszúrását a közlemény-azonosító után, ha erről a vonal üzemeltetéséért felelős Hatóságok megállapodást kötöttek. Az ilyen további szolgálati információ elé egy SZÓKÖZT [→] kell tenni, majd ezt legfeljebb tíz karakter követheti, melyeket a közlemény fej-részébe kell beilleszteni, közvetlenül a csatorna-sorszám utolsó számjegye után, és nem tartalmazhatnak semmilyen kijelölési funkciót. Ha ilyen tájékoztatást nem szúrtak be, akkor a 4.4.15.1.1.4 pontban részletezett adatok után közvetlenül a 4.4.15.2 pontban leírt adatok következzenek.

4.4.15.2 *Címzés*

4.4.15.2.1 A címzés az alábbi elemekből kell, hogy álljon:
a) kijelölési funkció [<≡];
b) elsőbbségi jel;
c) címzett(ek) megjelölése;
d) kijelölési funkció [<≡].

4.4.15.2.1.1 Az elsőbbségi jelnek - a feladó által hozzárendelt - megfelelő két-betűs csoportból kell állnia a következőknek megfelelően:

zlemény rész		A közlemény rész összetevője	Az összetevő eleme		Távgépíró jele
A FEJRÉSZ	FEJRÉSZ SOR (ld. 4.4.15.1.1)	A "Fejrész Kezdete" karakter	Egy karakter (0/1)		**SOH**
		Közlemény azonosító	a) Egy szóköz b) Vevő terminál betűjele c) Csatorna - azonosító betű d) Csatorna sorszám	(Példa: NRA062)	......
		(ha szükséges) további szolgálati jelölések, tájékoztatások	a) Egy szóköz b) Nem több, mint legfeljebb a sor végéig	(Példa: 270930)	→
	CÍMZÉS (ld. 4.4.15.2.1)	Szövegigazító funkció	Egy KOCSI-VISSZA, egy SOREMELÉS		<≡
		Elsőbbségi jelzés	a megfelelő kétbetűs csoport		• •
		Címzett(ek) megjelölése	Egy szóköz Egy nyolcbetűs csoport **(Példa: → EGLLZRZX → EGLLYKYX → EGLLACAD)**	sorban minden címzettnek	
	FELADÓ RÉSZ (ld. az 4.4.15.2.2.)	Szövegigazító funkció(k)	Egy KOCSI-VISSZA, egy SOREMELÉS		<≡
		Feladási idő	6 számjegyből álló dátum-idő csoport, amikor a közleményt továbbításra benyújtották		......
		Feladó megjelölése	a) Egy szóköz b) Egy nyolcbetűs csoport a feladó azonosítására		→......
		Elsőbbségi Riasztó Jelzés (csak távgépíró üzemmódban használják Vészhelyzeti-közlemények esetén)	Öt karakter (0/7)(BEL)		
		Opcionális Fejrész információ	További adatok, legfeljebb a sor végéig. Ld. 4.4.15.2.2.6		
		Szövegigazító funkció	Egy KOCSI-VISSZA, egy SOREMELÉS		<≡
		Szöveg eleje karakter	Egy karakter (0/2)		**STX**
	SZÖVEG (Ld. 4.4.15.3)	Szöveg kezdete	(ha szükséges) a címzett(ek) közelebbi megjelölése *(ha szükséges)* valamint mindegyik után egy KOCSI VISSZA, egy SOREMELÉS. Az angol FROM szó (ha szükséges) (Ld.4.4.15.3.5) A feladó közelebbi megjelölése *(ha szükséges)* Az angol STOP szó, melyet egy KOCSI VISSZA, egy SOREMELÉS követ *(ha szükséges)* (Ld. 4.4.15.3.5) és/vagy a feladó hivatkozási adata *(ha használnak ilyet)*		
		A közlemény szövege	A közlemény szövege, mely szöveg minden nyomtatott sorát egy KOCSI-VISSZA, egy SOREMELÉS karakter zár, kivéve az utolsó sort (Ld. 4.4.15.3.6)		
		Megerősítés *(ha szükséges)*	a) Egy KOCSI-VISSZA, egy SOREMELÉS b) a CFM rövidítés, melyet a szöveg megerősítendő része követ		
		Javítás *(ha szükséges)*	a) Egy KOCSI-VISSZA, egy SOREMELÉS b) a COR rövidítés, melyet a megelőző szövegben elkövetett hibák javítása követ		
	ZÁRÓRÉSZ (Ld. 4.4.15.3.12.1)	Szövegigazító funkció	Egy KOCSI-VISSZA, egy SOREMELÉS		<≡
		Lapemelés	Egy karakter (0/11)		VT
		"Szöveg vége" karakter	Egy karakter (0/3)		ETX

4-4. ábra Az 5-ös számú Nemzetközi ABC (IA-5)

(ez az ábra a 4.4.15 pont alatt részletezett közlemény-formátumot mutatja be)

Elsőbbségi jelzés	*Közlemény kategóriája*
SS	vészhelyzeti közlemények
DD	sürgősségi közlemények (*lásd* a 4.4.1.1.2 pontot)
FF	repülésbiztonsági közlemények (*lásd* a 4.4.1.1.3 pontot)
GG	meteorológiai közlemények (*lásd* a 4.4.1.1.4 pontot)
GG	a repülések rendszerességét elősegítő közlemények (*lásd* a 4.4.1.1.5 pontot)
GG	légiforgalmi tájékoztató szolgálatok közleményei (*lásd* a 4.4.1.1.6 pontot)
KK	légiforgalmi adminisztrációs közlemények (*lásd* a 4.4.1.1.7 pontot)
ahogy megfelelő	szolgálati közlemények (*lásd* a 4.4.1.1.9 pontot)

4.4.15.2.1.2 Az elsőbbségi sorrend megegyezik a 4.4.1.2 pontban leírtakkal.

4.4.15.2.1.3 Minden címzett megjelölés elé egy SZÓKÖZt kell tenni, kivéve, ha az a második vagy harmadik címzett sorban található első ilyen címzett megjelölés. A címzett megjelölés az alábbi elemekből kell, hogy álljon:
a) a célállomás négy-betűs helység jelölése;
b) a címzett szervezetet (légiforgalmi hatóságot, szolgálatot, vagy légijármű üzemeltető ügynökséget) azonosító három-betűs jelzés;
c) egy további betű, amely a címzett szervezeten belül egy osztályt, részleget, vagy eljáró egységet azonosít. Az X betűt kell használni helykitöltésre, ha ilyen további azonosításra nincs szükség.

4.4.15.2.1.3.1 Ha egy közleményt olyan szervezetnek kell címezni, amelynek nem osztottak ki a 4.4.15.2.1.3 pontban leírt típusú ICAO három-betűs jelzést, akkor a célállomás négy-betűs helység jelölése után az ICAO három-betűs YYY (vagy, katonai szervezet, vagy szolgálat esetében az ICAO három-betűs YXY) jelzést kell írni. A címzett szervezet nevét ilyenkor a közlemény szövegének első elemeként kell feltüntetni. Az ICAO három-betűs YYY vagy YXY jelzés után a következő (nyolcadik) betűnek a helykitöltő X betűnek kell lennie.

4.4.15.2.1.3.2 Amikor egy közleményt egy repülésben lévő légijárműnek kell megcímezni, és a közlemény - mielőtt a Légiforgalmi Mozgó Szolgálat továbbítaná - útjának egy részét az AFTN hálózaton keresztül teszi meg, akkor annak a légiforgalmi állomásnak a helység jelölése után, amelynek továbbítania kell a közleményt a légijármű részére, az ICAO három-betűs ZZZ jelzést kell írni. Ezután a légijármű azonosítóját a közlemény szövegrészének első elemeként kell feltüntetni. Az ICAO három-betűs ZZZ jelzés után a következő (nyolcadik) betűnek a helykitöltő X betűnek kell lennie.

4.4.15.2.1.4 A teljes címzés a nyomtatott példányon legfeljebb három sort foglalhat el, és a 4.4.16 pontban leírtak kivételével, külön címzett megjelölést kell használni minden egyes címzettre, akár egy helyen találhatók azok, akár nem.

4.4.15.2.1.5 A címzett megjelölés csoportok befejezése után közvetlenül egy kijelölési funkciót kell beilleszteni.

4.4.15.2.1.6 Ha a közleményt továbbításra nyomtatott formában veszik át, és a közlemény több címzett megjelölést tartalmaz, mint amennyi a nyomtatott lapon három sorban elfér, akkor az ilyen közleményeket, tovább-küldés előtt két vagy több közleményre kell bontani, amelyek már megfelelnek a 4.4.15.2.1.5 pont előírásainak. Az ilyen átalakítás során - amennyire az gyakorlatilag lehetséges - a címzett-megjelöléseket olyan sorrendbe kell rendezni, hogy a soron- következő távközlési központokban a lehető legkevesebb számú újra-feladásra legyen szükség.

4.4.15.2.2 *Feladó rész*

A feladó résznek az alábbi elemekből kell állnia:
a) feladási idő;
b) feladó megjelölése;
c) elsőbbségi jelzés (ha szükséges);
d) választható fej-rész információ;
e) kijelölési funkció [<≡];
f) szöveg-kezdete karakter, a 0/2 karakter (STX).

4.4.15.2.2.1 A feladási idő egy hat-számjegyű dátum-idő csoportból kell, hogy felépüljön, mely azt jelzi, hogy a közleményt feladásra mikor nyújtották be (*lásd* a 3.4.2 pontot).

4.4.15.2.2.2 A feladó megjelölése, amely elé közvetlenül egy SZÓKÖZt kell tenni, a következő elemekből kell, hogy álljon:
a) a feladás helyének négy-betűs helység jelölése;
b) a közleményt feladó szervezetet/hatáskört (légiforgalmi hatóságot, légiforgalmi szolgálatot vagy légijármű-üzemeltető ügynökséget) azonosító három-betűs jelzés;
c) egy további betű, amely a feladó szervezeten belül egy osztályt, részleget vagy eljáró egységet azonosít. Az X betűt kell használni helykitöltésre, ha ilyen további azonosításra nincs szükség.

4.4.15.2.2.3 Ahol a közlemény feladója olyan szervezet, amelynek nem osztottak ki a 4.4.15.2.2.2 pontban leírt típusú ICAO három-betűs jelzést, a feladás helyének négy-betűs helység jelölése után azonnal az ICAO három-betűs YYY jelzést és a helykitöltő X betűt kell írni (vagy, katonai szervezet vagy szolgálat esetében az ICAO három-betűs YXY jelzést és a helykitöltő X betűt kell írni). A szervezet (vagy katonai szolgálat) nevét ezután a közlemény szövegének első elemeként kell feltűntetni.

4.4.15.2.2.3.1 Az AFTN-en továbbított olyan közlemények számára, amelyeket egy másik hálózatban adtak föl, ki kell jelölni egy érvényes AFTN feladó megjelölést, amelyet - megegyezés alapján - az AFTN-t a külső hálózattal összekötő relé- (relay), vagy kapu- (gateway) berendezés használ.

4.4.15.2.2.4 Ha a közlemény feladója egy repülésben lévő légijármű, és a közleményt útvonalának egy részén az AFTN hálózaton keresztül kell tovább-küldeni, mielőtt kézbesíteni lehetne, akkor a feladó megjelölése annak a légiforgalmi állomásnak a négy-betűs helység jelölése, amely a közleményt az AFTN-nek továbbította, majd az ICAO három-betűs ZZZ jelzés és a helykitöltő X betű következik. A légijármű azonosítóját (hívójelét) ezután a közlemény szövegének első elemeként kell megadni.

4.4.15.2.2.5 Az elsőbbségi jelzést csak vészhelyzeti közlemények esetében kell használni. Amikor használják, akkor öt egymás után következő BEL (0/7, csengő) karakterből kell, hogy álljon.

Megjegyzés.- Az elsőbbségi jelzés a vevő távgépíró-készülékben lévő csengőt (figyelemfelkeltő jelzést) szólaltatja meg, eltérően a teljesen automatikus távközlési állomások esetén, melyek hasonló figyelmeztető jelzést adhatnak az SS sürgősségi jelzés észlelésekor, ezáltal riasztják az átjátszó központokban a felügyelő személyzet, az alárendelt állomásokon pedig a kezelő személyzet figyelmét, és így a közleményre azonnali figyelmet fordíthatnak.

4.4.15.2.2.6 A feladó sorban további szabadon választható adatok közlését is meg kell engedni, feltéve, hogy teljes hossza nem haladja meg a 69 karaktert, és hogy ez az érintett Hatóságok megállapodásának tárgyát képezi.

4.4.15.2.2.6.1 **Ajánlás. -** *A szabadon válaszható adatmező kezdetét egy SZÓKÖZzel, a végét egy kijelölési funkcióval kell jelezni.*

4.4.15.2.2.6.2 **Ajánlás. -** *Ha egy közleményben a 'forrás' és a 'cél' címzések között további címzési információk cseréje szükséges, akkor azt lehetőleg a szabadon választható adatmezőben (ODF) tegyék, az alábbi meghatározott formátumban:*
a) a kiegészítő címzés funkció paraméter-kódját egy egyes karakterrel és egy ponttal (1.) jelezzék;
b) ezután három módosító karakter és egy egyenlőségjel (=) következzen és a kiadott 8-betűs ICAO címzés; majd
c) a kiegészítő címzés paraméter-mezőjét egy kötőjellel (-) zárják le.

4.4.15.2.2.6.2.1 **Ajánlás. -** *Amikor a szolgálati közleményekre, vagy kérdésekre a külön cím nem egyezik meg a feladó megjelölésével, akkor lehetőleg az SVC módosító jelzést kell használni.*

4.4.15.2.2.7 A feladó részt egy kijelölési funkcióval [<≡] és a “szöveg-kezdete” (STX) (0/2) karakterrel kell lezárni.

4.4.15.3 *Szöveg*

4.4.15.3.1 A közlemények szövegét a 4.1.2 pont előírásainak megfelelően kell megfogalmazni, és az STX és az ETX között lévő valamennyi adatból kell állnia.

Megjegyzés.- Ha a közlemény szövegét nem kell ITA-2 kódba és formátumba átalakítani, és nem ütközik azokkal az ICA0 közlemény típusokkal vagy formátumokkal, amelyek a PANS - ATM-ben (Doc 4444) vannak leírva, a Hatóságok teljes mértékben kihasználhatják az 5-ös számú Nemzetközi ABC-ben (IA-5) rendelkezésre álló karaktereket.

4.4.15.3.2 Ha feladóra vonatkozó hivatkozási adatot használnak, akkor azt a szöveg elejére kell tenni, kivéve a 4.4.15.3.3 és a 4.4.15.3.4 pontban megadottakat.

4.4.15.3.3 Ha a címzett megjelölés második elemét, az YXY, azYYY vagy a ZZZ három-betűs ICAO jelölés alkotja (*lásd* a 4.4.15.2.1.3.1 és a 4.4.15.2.1.3.2 pontokat), és ezért szükségessé válik a szövegben a közlemény címzettjének közlése, akkor ezt az azonosító karakter-csoportot a feladóra való hivatkozás elé kell írni (ha van ilyen), és ezzel ez a szöveg első elemévé válik.

4.4.15.3.4 Ha a feladó megjelölés második elemét az YXY, az YYY vagy a ZZZ három-betűs ICAO jelzés alkotja (*lásd* a 4.4.15.2.2.3 és 4.4.15.2.2.4 pontokat), és ezért szükségessé válik a szövegben a közleményt feladó szervezet (vagy katonai szolgálat), vagy a légijármű nevének közlése, akkor ezt az azonosítót a szöveg első elemeként kell megadni.

4.4.15.3.5 Amikor a 4.4.15.3.3 és a 4.4.15.3.4 pontok előírásait alkalmazzák olyan közlemények esetében, amelyekben az ICAO három-betűs YXY, YYY vagy ZZZ jelzéset két vagy több különböző szervezet (vagy katonai szolgálat) megjelölésére is használták, akkor a szövegben a további azonosítók sorrendje meg kell, hogy egyezzen a közlemény címzés- és címzett-megjelölésében használt teljes sorrenddel. Ilyen esetben minden címzett megjelölés után egy kijelölési funkciót kell tenni. A közleményt feladó (YXY, YYY vagy ZZZ jelzéssel megjelölt) szervezet neve elé ilyenkor a "FROM" szót kell írni. Az azonosítók után, a szöveg többi része elé, a "STOP" szót kell írni, amelyet egy kijelölési funkció kell, hogy kövessen.

4.4.15.3.6 A szöveg minden nyomtatott sora után egy kijelölési funkciót kell küldeni. A távgépíró üzemben - ha a szöveg egy részét meg kívánják erősíteni, akkor - a megerősítést az utolsó szöveg-csoporttól egy kijelölési funkcióval kell elválasztani [<≡], és ezt a CFM rövidítéssel kell jelezni, amely után a megerősített szöveg-rész következik.

4.4.15.3.7 Ha a közleményeket "off-line", hálózati kapcsolat nélküli üzemmódban, vagyis papírszalag lyukasztásával készítik el, akkor a szövegben elkövetett hibákat úgy kell kijavítani, hogy visszaléptetik, és a hibás karaktereket a DEL (7/15) karakterrel írják felül.

4.4.15.3.8 "On-line" üzemmódban (azaz hálózati kapcsolatban), a szövegben elkövetett hibákat úgy kell javítani, hogy közvetlenül a hiba után beszúrják az →E→E→E→ jel-sorozatot, majd újragépelik az utolsó helyes szót (vagy szócsoportot).

4.4.15.3.9 Ha nem fedezik fel, csak a feladási folyamat későbbi fázisában, hogy a szövegben hiba történt, akkor a javítást az utolsó szöveg-csoporttól, vagy megerősítéstől (ha van ilyen) egy kijelölési funkcióval [<≡] kell elválasztani. Ezután a COR rövidítésnek és a javított szövegnek kell következnie.

4.4.15.3.10 Az állomásoknak el kell végezniük a nyomtatott példányon minden jelzett javítást, mielőtt a közleményt helyben kézbesítik, vagy kézi üzemeltetésű vonalra vinnék át.

4.4.15.3.11 Az AFTN feladó állomás által begépelt szövegek nem lehetnek 1800 karakternél hosszabbak. Az AFTN feladó állomásnak az 1800 karakternél hosszabb AFTN közleményeket külön közleményekre bontott formában kell, hogy feladja. A II. kötet "B" melléklete tartalmaz útmutató anyagot arra vonatkozóan, hogy egy hosszú közleményt hogyan kell különálló közleményekre bontani. Ha a közleményeket vagy adatokat csak közepes, vagy nagy sebességű vonalakon továbbítják, akkor a szöveg lehet 1800 karakternél hosszabb is, feltéve, ha ettől a hálózat, vagy a vonal teljesítmény-karakterisztikája nem romlik, és ha erről az érintett Hatóságok megállapodást kötöttek.

Megjegyzés.- A karakterek számába beleszámít a szöveg-formátum minden nyomtatható és nem nyomtatható (vezérlő) karaktere, amelyek a „szöveg-eleje” jel és a záró rész első kijelölésió funkciója között vannak, de ezeket az előbbieket kivéve.

4.4.15.3.12 *Záró rész*

4.4.15.3.12.1 A közlemény záró része az alábbi elemekből kell, hogy álljon, a megadott sorrendben:
a) egy kijelölési funkció [<≡] a szöveg utolsó sora után;
b) lap-emelés karakter, a 0/11 karakter (VT / Függőleges Tabulátor/);
c) szöveg-vége karakter, 0/3 (ETX).

4.4.15.3.12.1.1 **Ajánlás. -** *Az állomás 5-ös számú Nemzetközi ABC-t (IA-5) használó terminál-berendezései (lapnyomtatók) lehetőség szerint legyenek képesek arra, hogy elegendő számú soremelés jelet generáljanak a helyi állomás számára, ha FÜGGŐLEGES TABULÁTOR (0/11) karaktert vesznek.*

4.4.15.3.12.1.2 **Ajánlás. -** *Ha a közlemény nem halad át ITA-2 kódot használó AFTN hálózati szakaszokon, vagy ha a Hatóságok intézkedtek arról, hogy a közleményhez automatikusan hozzáadják a második kocsi vissza jelet, mielőtt egy ITA-2 kódot használó vonalra küldik a közleményt, akkor a kijelölési funkcióban és a sor- vége funkcióban megengedhető az egy kocsi vissza jel használata, ha erről az érintett Hatóságok megállapodást kötöttek.*

4.4.15.3.12.1.3 Az AFTN feladó állomás által benyújtott közlemények nem lehetnek 2100 karakternél hosszabbak.

Megjegyzés.- A karakterek számába beleszámít minden nyomtatható és nem nyomtatható (vezérlő) karakter, amely a közleményben található, beleértve a fejrész-kezdete (SOH /Start-of-Heading/) karaktertől a szöveg-vége karakterig.

4.4.15.4 A 4.4.15.5 - 4.4.15.6 és a 4.4.16 pontokban leírt eseteket kivéve, az IA-5 kódban írt közleményekre a 4.4.8 és a 4.4.9-től a 4.4.13-ig terjedő pontokban leírt eljárásokat kell alkalmazni.

4.4.15.5 *Csatorna-ellenőrző adások.* Abban az esetben, ha a csatorna állapotának folyamatos ellenőrzése nem biztosított, a távgépíró-vonalakon az alábbi jelsorozatot kell rendszeres időközönként leadni:

1) fejrész-sor	(*lásd* a 4.4.15.1.1 pontot);
	S
2) kijelölési funkció	T ;
	X
3) az eljárás-jelzés	CH ;
	E
4) kijelölési funkció	T .
	X

A vevő állomásnak ezután ellenőriznie kell a bejövő adás azonosítóját, hogy megbizonyosodjon arról, beleillik-e az az azon a csatornán vett adások sorozatába.

Megjegyzés. - Ennek az eljárásnak az alkalmazása bizonyos mértékig biztosítani képes a csatornán az adások folytonosságának fenntartását; ennél azonban sokkal kedvezőbb a folyamatosan ellenőrzött csatorna használata, mivel ezzel az adatok sértetlensége is javul.

4.4.15.5.1 **Ajánlás. -** *Ha egy vonal az adott pillanatban nem foglalt és nem folyamatosan ellenőrzött, akkor az ellenőrzést a 4.4.15.5 pontban leírt adást lehetőség szerint minden órában, minden óra 20 perckor és minden óra 40 perckor végezzék el (H + 00; H + 20; H + 40).*

4.4.15.6 A vészhelyzeti közlemények (distress messages) (SS elsőbbségi jelzéssel, *lásd* a 4.4.1.1.1 pontot) vételét az AFTN célállomásnak egyedileg kell nyugtáznia úgy, hogy szolgálati közleményt (*lásd* a 4.4.1.1.9 pontot) küld a feladó AFTN állomásnak. A vétel nyugtázását az AFTN feladó állomásnak címzett teljes közlemény formájában kell elvégezni, amelyet SS elsőbbségi jelzéssel és az ehhez kapcsolódó sürgősségi figyelem-felhívó jelzéssel *(lásd* a 4.4.16.2.2.5 pontot) kell ellátni. A közlemény szövege a következő kell, hogy legyen:
1) az R eljárás-jelzés;
2) a nyugtázott közlemény feladó-sora (lásd a 4.4.15.2.2 pontot), az elsőbbségi figyelem-felhívó jelzés, vagy a szabadon választható fej-rész információk nélkül;
3) a záró rész (lásd a 4.4.15.3.12.1 pontot).

Megjegyzés. - Az alábbi példa a 4.4.15.6 pontban leírt eljárás alkalmazását mutatja be:
Fej-rész (*lásd* a 4.4.15.1.1 pontot)
<≡ SS → LECBZRZX <≡
121322 → EGLLYFYX (elsőbbségi figyelem-felhívó jelzés) <≡
S
TR→ 121319 → LECBZRZX<≡
X
Záró rész (*lásd* a 4.4.15.3.12.1 pontot).

4.4.16 Intézkedések abban az esetben, ha a számítógépes AFTN átjátszó állomás sérült, IA-5 kódú közleményt talál.

4.4.16.1 A folyamatosan ellenőrzött csatornákon a sérülés észlelése és annak javítása az összeköttetést ellenőrző protokol feladata kell, hogy legyen, ezért ilyenkor a későbbi szolgálati közlemények, vagy a "CHECK TEXT NEW ENDING ADDED" (“ellenőrizze a szöveget, a közlemény új záró részt kapott”) szövegű közlemények küldésére nincs szükség.

4.4.16.2 Azokon a csatornákon, melyeken nem alkalmaznak folyamatos ellenőrzést, az átjátszó állomásnak az alábbi eljárásokat kell követnie:

4.4.16.2.1 Ha egy közlemény vétele közben az átjátszó állomás azt észleli, hogy a közlemény - még a "szöveg-vége" karakter előtt - valamelyik ponton megsérült, akkor: 1) a közlemény tovább-küldésére vonatkozó kötelezettségét érvényteleníti; 2) szolgálati közleményt kell küldenie a közleményt továbbító állomásnak, amelyben a közlemény ismételt feladását kéri.

Megjegyzés. - Az alábbi példa bemutatja egy ilyen szolgálati közlemény tipikus szövegét, amelyben egy sérült közleménnyel kapcsolatban a fenti eljárást alkalmazták:
SVC→QTA→RPT→ABC 123 (zárór ész - *lásd* a 4.4.15.3.12.1 pontot)

4.4.16.2.2 Amikor a 4.4.16.2.1 pont előírásait alkalmazzák, a szolgálati közleményt vevő állomás újra magára kell, hogy vállalja az említett közleményért a felelősséget, egy új - (azaz sorrendileg helyes) - közlemény-azonosítóval (lásd a 4.4.15.2.1 pontot). Ha ennek az állomásnak nem áll rendelkezésére az eredeti közlemény hibátlan példánya, akkor egy közleményt kell küldenie a feladónak, akit a sérült közlemény feladó megjelölése azonosít, amelyben a hibásan vett közlemény ismétlését kéri.

Megjegyzés. - Az alábbi példa bemutatja egy ilyen szolgálati közlemény tipikus szövegét, amelyben a fenti eljárást alkalmazták egy sérült közleménnyel kapcsolatban, amelynek feladó része "141335 CYULACAX" volt:
SVC→QTA→RPT→141335→CYULACAX
(zárórész - *lásd* 4.4.15.3.12.1)

4.4.16.3 Ha egy átjátszó állomás a közlemény szöveg-részének leadása után észleli, hogy a közleményben nincs teljes szöveg-vége karakter, de gyakorlatilag nincs lehetősége kideríteni, hogy a hiba csak a szöveg-vége karaktert érintette, vagy a hiba következtében az eredeti szöveg egy része is elveszett, akkor a csatornára a következő üzenetet küldi:
1) <≡CHECK≡TEXT≡
NEW→ENDING→ADDED
2) a saját állomás azonosítója;
3) (záró rész - *lásd* a 4.4.15.3.12.1 pontot).

4.4.17 AFTN közlemények továbbítása kód- és bájt-független vonalakon és hálózatokon

Amikor az AFTN közleményeket az AFS (Légiforgalmi Állandóhelyű Szolgálat /Aeronautical Fixed Service/) kód- és bájt-független vonalain és hálózatain továbbítják, az alábbi előírásokat kell alkalmazni.

4.4.17.1 A 4.4.17.3 pontban leírtakat kivéve, a közlemény fej-rész sorát el kell hagyni. A közleménynek egy kijelölési funkcióval kell kezdődnie, amelyet a címzés követ.

4.4.17.2 A közleménynek teljes záró résszel kell végződnie.

4.4.17.3 **Ajánlás. -** *Műszaki ellenőrzés céljára a belépő központoknak lehetőség szerint meg kell engedni, hogy további adatokat küldjenek a vonalra, a közlemény első kijelölési funkciója előtt és/vagy záró része után. Az ilyen adatokat a vevő állomás figyelmen kívül hagyhatja.*

4.4.17.3.1 Amikor a 4.4.17.3 pont előírásait alkalmazzák, a hozzáfűzött kiegészítő adatok között nem fordulhat elő sem KOCSI-VISSZA, sem SOREMELÉS karakter, sem a 4.1.2.4 pontban felsorolt bármelyik kombináció.

4.5 Az ICAO Közös Adattovábbító Hálózata (CIDIN)

1. Megjegyzés. - Az ICAO Közös Adattovábbító Hálózata (CIDIN) /Common ICAO Data Interchange Network/ egyedi alkalmazásokból és a föld-föld közlemények cseréjére létesített, összeköttetést biztosító szolgáltatások- ból épül fel, a Nemzetközi Távíró és Távbeszélő Bizottság (CCITT) /Comite Consultatif International Telegraphique et Telephonique/ X.25 Ajánlásán alapuló protokolokat *használ, hogy ezzel kód- és bájt-független kommunikációs hátteret, eszközöket biztosíthasson.*

2. Megjegyzés. - Az ICAO Közös Adattovábbító Hálózatának (CIDIN) legfontosabb célja az, hogy javítsa az AFTN-t, valamint hogy támogassa a nagyméretű közlemények továbbítását és a rendszerrel szemben nagyobb követelményeket támasztó alkalmazások működését, mint például amilyen az Üzemeltetési Meteorológiai Információ-szolgáltatás (OPMET) is, két vagy több földi rendszer között.

3. Megjegyzés. - Az Európában alkalmazott CIDIN összekötetési eljárásokat részletesen az EUR CIDIN Kézikönyv mutatja be.

4.6 Az ATS /Légiforgalmi Szolgálatok/ Közleményeit Kezelő Szolgáltatás (ATSMHS)

Az ATS /Légiforgalmi Szolgálatok/ közleményeit kezelő szolgáltató (ATSMHS) alkalmazás, ATS közlemény szolgáltatását kell igénybe venni a felhasználók közötti ATS közlemények cseréje céljából az ATN (Légiforgalmi Távközlési Hálózat /Aeronautical Telecommunication Network/) hálózatok közötti összeköttetéseken keresztül.

1. Megjegyzés. - Az ATS (Légiforgalmi Szolgálatok) közlemények kezelését végző számítógépes szolgáltatói alkalmazásban az "ATS közlemény szolgáltatás" (ATS message service) célja az, hogy a közleményekkel kapcsolatosan általános szolgáltatásokat biztosítson az ATN Internet Összeköttetési Szolgáltatásán /ATN Internet Communication Service/ (ICS) keresztül. Ez adott esetben összeköttetési rendszerként használható, melyben a felhasználók számítógépes alkalmazásai (programjai) az ATN-en keresztül kommunikálnak egymással. Ezt például meg lehet valósítani az ATS közlemény szolgáltatáshoz kapcsolódó Felhasználói Program Interfészek /azaz összeköttetési kapcsolat-rendszerek/ (API = Application Program/me/ Interfaces) segítségével.

2. Megjegyzés. - Az ATS közlemények kezelését végző számítógépes szolgáltatói alkalmazás részletes leírása a Légiforgalmi Távközlési Hálózat (ATN) /Aeronautical Telecommunication Network/ Műszaki Előírások Kézikönyvé-ben *(Doc 9705), a III. Al-kötetben található.*

3 .Megjegyzés. - Az "ATS közlemény szolgáltatás"-t (ATS message service) - az ATN Internetes Összeköttetési Szolgáltatásán keresztül - az ISO/IEC (Nemzetközi Szabványügyi Szervezet/Nemzetközi Elektro- technikai Bizottság /International Organization for Standardization/International Electrotechnical Comission/) 10021-es, valamint az ITU-T (Nemzetközi Távközlési Unió - Távközlési Szabványosítási Szektora /International Telecommunication Union - Telecommunication Standardization Sector/) X.400-as előírása, és a Légiforgalmi Távközlési Hálózat (ATN) /Aeronautical Telecommunication Network/ Műszaki Előírások*kal foglalkozó* Kézikönyvben *(Doc 9705) található további követelmények alapján megvalósított közlemények kezelését végző számítógépes szolgáltatói alkalmazásokkal biztosítják. A két dokumentum-sorozat, azaz az ISO/IEC MOTIS (Nemzetközi Szabványügyi Szervezet/Nemzetközi Elektrotechnikai Bizottság, Közlemény-Központú Szöveg Közvetítő Rendszer /Message-Oriented Text Interchange System/) nemzetközi szabványai és az ITU-T X.400-as Ajánlásainak Sorozata (1988, vagy későbbi) elvben igazodik egymáshoz. Azonban csekély számban léteznek eltérések. Az előbb említett dokumentumban - ahol alkalmazható - hivatkozások találhatóak a vonatkozó ISO Nemzetközi Szabványokra és a Nemzetközi Szabványosítási Profilokra, Feladatkörökre (ISP /International Standairdized Profiles/). Ahol szükséges, például a kölcsönös együttműködés okán, vagy, hogy a különbségeket kihangsúlyozzák, oda hivatkozásokat helyeztek el a kapcsolódó X.400 Ajánlásokra.*

4. Megjegyzés. - Az ATS Közleményeket Kezelő szolgáltatásokat megvalósító alábbi ATN végfelhasználói rendszer ("end system") típusokat határozták meg a Légiforgalmi Távközlési Hálózat (ATN /Aeronautical Telecommunication Network/) Műszaki Előírásokkal *foglalkozó* Kézikönyv *(Doc 9705), III. Alkötetében:*
1) egy ATS közlemény központi kiszolgáló egység /szerver/;

2) egy ATS közlemény felhasználói ügynökség;
3) egy AFTN / AMHS (Légiforgalmi Állandóhelyű Távközlési Hálózat / ATS Közlemény Kezelő Rendszer /ATS message handling system/) közötti átjáró kapu (gateway); és
4) a CIDIN/AMHS (az ICAO Közös Adat-továbbító Hálózata /Common ICAO Data Interchange Network/ ATS Közlemény Kezelő Rendszer /ATS message handling system)/ közötti átjáró kapu (gateway).

Az előbbiekben felsorolt bármely két ATN végfelhasználói rendszer között kapcsolatot lehet teremteni az Internetes Összeköttetési Szolgáltatáson keresztül (lásd a 4-1 Táblázatot).

4-1. táblázat – Az ATS Közleményeket Kezelő szolgáltatásokat megvalósító ATN végfelhasználói rendszerek közötti összeköttetés

ATN 1.Végfelhasználói Rendszer	ATN 2. Végfelhasználói Rendszer
ATS Közlemény Szerver	ATS Közlemény Szerver
ATS Közlemény Szerver	AFTN/AMHS közötti átjáró kapu (gateway)
ATS Közlemény Szerver	CIDIN/AMHS közötti átjáró kapu (gateway)
ATS Közlemény Szerver	ATS Közlemény Felhasználói Ügynökség
AFTN/AMHS közötti átjáró kapu (gateway)	AFTN/AMHS közötti átjáró kapu (gateway)
CIDIN/AMHS közötti átjáró kapu (gateway)	CIDIN/AMHS közötti átjáró kapu (gateway)
CIDIN/AMHS közötti átjáró kapu (gateway)	AFTN/AMHS közötti átjáró kapu (gateway)

4.7 Központok-közötti Összeköttetés (ICC)

A központok-közötti összeköttetési (ICC) alkalmazások készletét kell alkalmazni az ATS közlemények cseréjére a Légiforgalmi Szolgálatok felhasználói között az ATN Interneten keresztül.

1. Megjegyzés. - Az ICC alkalmazások készlete lehetővé teszi az információk cseréjét az alábbi üzemeltetési szolgáltatások támogatására:
a) repülés bejelentése;
b) repülés koordinációja;
c) irányítás átadása és rádió-összeköttetés átadása;
d) repülés tervezés;
e) légtér-gazdálkodás; és
f) áramlás-szabályozás.

2. Megjegyzés. - Az ICC készlet számára kifejlesztett alkalmazások közül az első az ATS Berendezések Közötti Adat-összeköttetés (AIDC /ATS Interfacility Data Communication/)

3. Megjegyzés. - Az AIDC alkalmazás az olyan információk cseréjét biztosítja ATS egységek között (ATSUs /ATS Units/), mellyel támogatja az olyan kritikus légiforgalmi irányítási (ATC) funkciókat, mint amilyen a repülési adatok továbbítása az olyan légijárművekről, amelyek a FIR (Repülés-Tájékoztató Körzet /Flight Information Region/) határához közelednek, a határ átrepülési feltételeinek koordinálása, valamint az irányítási felelősség és az összeköttetés átadása.

4. Megjegyzés. - Az AIDC alkalmazás részletes specifikációja a Légiforgalmi Távközlési Hálózat (ATN /Aeronautical Telecommunication Network/) Műszaki Előírásai*val foglalkozó* Kézikönyvé*nek (Doc 9705), III. Alkötetében található.*

5. Megjegyzés. - Az AIDC alkalmazás csak szigorúan ATC alkalmazás, az ATS egységek közötti taktikai irányítási tájékoztatások, adatok cseréjére. Ez az alkalmazás nem támogatja az információcserét más berendezésekkel, intézményekkel.

6. Megjegyzés. - Az AIDC alkalmazás az alábbi üzemeltetési szolgáltatásokat támogatja:
a) repülés bejelentése;
b) repülés koordinációja;
c) a közvetlen irányítási felelősség átadása;
d) a rádió-összeköttetés átadása; és
e) általános információk továbbítása (repüléssel kapcsolatos adatok, vagy kötetlen szöveges üzenetek, közlemények, azaz nem kötött formátumú közlemény).

5. FEJEZET: LÉGIFORGALMI MOZGÓ SZOLGÁLAT – BESZÉD-ÜZEMŰ ÖSSZEKÖTTETÉSEK

5.1 Általános rész

Megjegyzés: Ezen rendelkezések értelmében a légiforgalmi mozgó szolgálatra alkalmazható össszekötetési eljárások - ahogy megfelelő - a légiforgalmi mozgó-műholdas szolgálatra is alkalmazhatók.

5.1.1 Bármilyen összeköttetés során, mindenkor a legmagasabb fokú fegyelmet kell tanúsítani.

5.1.1.1 Minden olyan helyzetben, amelyek esetére szabványos ICAO kifejezéseket határoztak meg, ezeket a kifejezéseket kell alkalmazni. Csak ha a szabványos kifejezések egy szándékolt átvitelre nem alkalmazhatók, akkor kell köznyelvet használni.

Megjegyzés. - Részletes nyelvismereti követelmények az Annex 1, Függelékében vannak feltüntetve.

5.1.1.2 Az 5.1.8 pontban meghatározott közleményeken kívül, kerülni kell a közlemények továbbítását a légiforgalmi mozgó szolgálat frekvenciáin akkor, amikor a légiforgalmi állandóhelyű szolgálat is képes a szándékolt célokat kielégíteni.

5.1.1.3 **Ajánlás. -** Valamennyi összeköttetés során tekintetbe kell venni az emberi teljesítőképesség azon korlátainak következményeit, melyek hatással lehetnek a közlemények hibátlan vételére és megértésére.

Megjegyzés. - Az emberi teljesítőképességgel foglalkozó tájékoztató anyag az Emberi Tényezők Képzési Kézikönyvben *(Doc 9683) található.*

5.1.2 Amikor arra van szükség, hogy egy légijármű állomás ellenőrzés vagy beállítás céljából adjon jeleket, - amelyek valószínűleg zavart fognak okozni egy szomszédos légiforgalmi állomás munkájában, - akkor ki kell kérni az illető állomás beleegyezését, mielőtt a jeleket leadják. Az ilyen adásokat a minimálisra kell korlátozni.

5.1.3 Amikor arra van szükség, hogy a légiforgalmi mozgó szolgálat egy állomása ellenőrző-jeleket adjon, akár az adó beállítására egy hívás előtt, akár a vevő beállítására, az ilyen jelek nem tarthatnak 10 másodpercnél tovább, tartalmát pedig a rádió-távbeszélő használata esetén kimondott számokból kell összeállítani (ONE/egy/, TWO/kettő/, THREE/három/, stb.), amelyeket az ellenőrző-jeleket adó állomás hívójele követ. Az ilyen adásokat a minimálisra kell korlátozni.

5.1.4 Ha egyéb előírás másképp nem rendelkezik, az összeköttetés felvétele annak az állomásnak a kötelessége, amelynek továbbítandó közleménye van.

Megjegyzés. - Azokra az esetekre, amikor SELCAL berendezést használatnak, az összeköttetés felvételére vonatkozó eljárásokat az 5.2.4 pont foglalja magába.

5.1.5 **Ajánlás. -** *Egy légiforgalmi állomás meghívása után legalább 10 másodperces szünet tartandó a második hívás előtt. Ennek célja a fölösleges hívások kiküszöbölése azon idő alatt, amíg a légiforgalmi állomás felkészül a legelső hívás megválaszolására.*

5.1.6 Ha egy légiforgalmi állomást egyszerre több légijármű állomás is hív, a légiforgalmi állomásnak kell eldönteni, hogy a légijárműveknek milyen sorrendben kell folytatniuk a közlemény-váltást.

5.1.7 A légijármű állomások közötti összeköttetés során a közlemény-váltás időtartamát a vevő légijármű állomás- nak kell meghatároznia, kivéve ha egy légiforgalmi állomás belép az összeköttetésbe. Ha az ilyen közlemény-váltás ATS frekvencián történne, akkor előzetesen kérni kell a légiforgalmi állomás beleegyezését. Rövid közlemény-váltásokhoz nem kell ilyen engedélyt kérni.

5.1.8 Közlemény-kategóriák

A légiforgalmi mozgó szolgálat által kezelt közlemények fajtáit, valamint az összeköttetés felvételekor és a közlemény-váltáskor alkalmazandó elsőbbségi sorrendet az alábbi táblázat tartalmazza.

Közlemény-kategória és elsőbbségi sorrend	*Rádiótávbeszélő jelzés*
a) Vészhelyzeti hívások, vészhelyzeti közlemények és vészhelyzeti forgalmazás	MAYDAY
b) Sürgősségi közlemények, beleértve azokat a közleményeket is, melyeket a betegszállító légijármű jelzés előzött meg	PAN, PAN vagy PAN, PAN MEDICAL
c) Irányméréssel kapcsolatos közlemények	-----
d) Repülésbiztonsággal kapcsolatos közlemények	-----
e) Meteorológiai közlemények	-----
f) Repülések rendszerességével kapcsolatos közlemények	-----

1. Megjegyzés. - A jogtalan beavatkozásra vonatkozó közlemények olyan kivételes körülményeket feltételeznek, amelyek esetleg megakadályozhatják az olyan elfogadott, megszokott közlemény-váltási eljárások alkalmazását, amelyek alapján a közlemények kategóriáját és elsőbbségét általában meghatározzák.

2. Megjegyzés. - A NOTAM-ok a c)-től f)-ig bármelyik sürgősségi kategóriába tartozhatnak. A NOTAM besorolását az határozza meg, hogy mi a tartalma, és hogy mennyire fontos az érintett légijármű(vek) számára.

5.1.8.1 A vészhelyzeti közleményeket és a vészhelyzeti forgalmazást az 5.3 pont előírásai szerint kell kezelni.

5.1.8.2 A sürgősségi közleményeket és sürgősségi forgalmazást, beleértve azokat a közleményeket is, amelyeket a betegszállító légijármű jelzéssel vezettek be, az 5.3 pont előírásai szerint kell kezelni.

Megjegyzés. - A "betegszállító" (medical transports) kifejezést az 1949-es Genfi Egyezmény és Kiegészítő Jegyzőkönyvei határozták meg (lásd még az RR S33 III. Rész), a következő jelentéssel: "bármely földi, vízi vagy légi közlekedési eszköz, akár polgári, akár katonai, ideiglenes vagy állandó, amelyet kizárólagosan egészségügyi szállításra (medical transportation) jelöltek ki, és amely a konfliktusban résztvevő valamelyik Fél illetékes hatóságának ellenőrzése alatt áll."

5.1.8.3 *Az irányméréssel kapcsolatos közlemény-váltásokat* a 6. Fejezet előírásai szerint kell kezelni.

5.1.8.4 *A repülésbiztonsággal kapcsolatos közlemények* az alábbiak lehetnek:
1) légijárművek mozgásával és irányításával kapcsolatos közlemények [*lásd* a PANS-ATM (Doc 4444) előírásait];
2) egy légijármű-üzemeltető ügynökség (járató) vagy egy légijármű által feladott közlemények, amelyek azonnali fontosságúak egy repülésben lévő légijármű számára;

3) meteorológiai tanácsadás, amely azonnali fontosságú egy repülésben lévő, vagy indulni készülő légijármű számára (akár egyedileg, akár általános adással leadott közleményről van szó);
4) egyéb olyan közlemények, amelyek repülésben lévő, vagy indulni készülő légijárműve(ke)t érintenek.

5.1.8.5 A *meteorológiai közlemények* légijárművektől származó, vagy légijárműveknek szóló meteorológiai tájékoztatást tartalmaznak, kivéve az 5.1.8.4 pont 3) bekezdésben említetteket.

5.1.8.6 A *repülések rendszerességével kapcsolatos közlemények* az alábbiak lehetnek:
1) a légijárművek üzemeltetésének biztonsága vagy rendszeressége szempontjából alapvető fontosságú létesítmények üzemeltetésével vagy karbantartásával kapcsolatos közlemények;
2) légijárművek szervizelésével kapcsolatos közlemények;
3) rendelkezések a légijármű járató képviselői felé, ha a rendes üzemeltetési menetrendtől történt elkerülhetetlen eltérés miatt az utasokkal és a személyzettel kapcsolatos követelmények megváltoztak. Az utasok vagy a személyzet egyéni igényeinek továbbítása nem megengedett ebben a közlemény fajtában;
4) a légijármű által végrehajtandó, a szokásostól eltérő leszállásokkal kapcsolatos közlemények;
5) azonnal szükséges légijármű-alkatrészekkel és -anyagokkal kapcsolatos közlemények;
6) a légijárművek üzemeltetési menetrendjében történt változásokkal kapcsolatos közlemények.

5.1.8.6.1 A közvetlen légijármű-vezető - légiforgalmi irányító összeköttetési csatornákat használó légiforgalmi szolgálati egységektől csak akkor várható el, hogy a repülések rendszerességét, folyamatosságát szolgáló közleményeket továbbítsanak, ha ez nem akadályozza elsődleges feladataik ellátását, és közben más csatorna nem áll rendelkezésre az ilyen közlemények kezelésére.

Megjegyzés. - A fenti 5.1.8.4 pont 2) bekezdésében és az 5.1.8.6 pont 1)-től 6)-ig terjedő bekezdéseiben említett közlemények tipikus példái az 1. Fejezetben részletesen leírt repülés-üzemi felügyeleti összeköttetéseknek .

5.1.8.7 **Ajánlás. -** *Lehetőség szerint az azonos elsőbbségű közleményeket általában olyan sorrendben kell továbbítani, amilyen sorrendben azokat továbbításra megkapták.*

5.1.8.8 A légijármű-vezetők közötti levegő-levegő közlemény-váltások tárgya a repülések biztonságosságát és rendszerességét befolyásoló bármilyen közlemény lehet. Ezeknek a közleményeknek a kategóriáját és elsőbbségét - az 5.1.8 ponttal összhangban - a tartalmuk alapján kell megállapítani.

5.1.9 Közlemények törlése

5.1.9.1 *Befejezetlen adások.* Amikor egy közleményt még nem adtak le teljes egészében, amint utasítás érkezik a közlemény törlésére, akkor a közleményt továbbító állomásnak utasítania kell a vevő állomást a befejezetlen adás figyelmen kívül hagyására. Ezt a megfelelő rádió-távbeszélő kifejezés használatával kell megtenni.

5.1.9.2 *Befejezett adások*

Ajánlás. - *Amikor egy befejezett közleményt helyesbítésre várva függőben tartanak, és a vevő állomást tájékoztatni kell arról, hogy a közleményt ne továbbítsa, vagy amikor a közleményt nem lehet a címzetthez eljuttatni illetve tovább-küldeni, akkor az adást törölni kell. Ezt a megfelelő rádió-távbeszélő kifejezés használatával kell megtenni.*

5.1.9.3 Az adást törlő állomás felelős minden szükséges további intézkedés megtételeéért.

5.2 Rádió-távbeszélő eljárások

Megjegyzés. - Amikor Kiválasztó Hívás (Selective Calling /SELCAL/) berendezést használnak, akkor bizonyos itt következő előírások helyett az 5.2.4 pontban leírt előírások válnak érvényessé.

5.2.1 Általános rész

5.2.1.1 **PANS. - *(Légiforgalmi Szolgálatok Eljárásai)*** – *Amikor a légiforgalmi irányító, vagy a légijármű- vezető beszéd-üzemű összeköttetéstt kezdeményez, akkor az erre adott válasznak is beszéd-üzeműnek kell lennie. A 8.2.12.1 pontban leírtak kivételével, ha a légiforgalmi irányító, vagy a légijárművezető CPDLC- /légiforgalmi igányító - légijárművezető közötti digitális adatcseré/-n keresztül kezdeményez összeköttetést, akkor az erre adott válasznak is CPDLC-n keresztül kell érkeznie.*

5.2.1.2 A használandó nyelv

5.2.1.2.1 A levegö-föld rádió-távbeszélő összeköttetést a földi állomás által rendszeresen használt nyelven, vagy angol nyelven kell lebonyolítani.

1. Megjegyzés. - A földi állomás által rendes körülmények között használt nyelv nem feltétlenül egyezik meg annak az Államnak a nyelvével, ahol a földi állomás található. Megállapodás lehetséges a közös nyelvhasználatra - körzeti előírásként - az egy *adott körzetbden lévő földi állomások számára.*

2. Megjegyzés. - A légiforgalmi rádió-távbeszélő összeköttetéseknél megkövetelt nyelvismeret szintjét az Annex 1, Függeléke határozza meg.

5.2.1.2.2 Az angol nyelvnek "rendelkezésre kell állnia" bármely légijármű fedélzeti állomás kérésére, és ezen a nyelven "kell rendelkezésre állnia" minden olyan földi állomásnak, amely nemzetközi légiközlekedési szolgálatok általi használatra kijelölt repülőtereket és útvonalakat szolgál ki.

5.2.1.2.3 Egy adott földi állomáson rendelkezésre álló nyelveknek a Légiforgalmi Tájékoztató Kiadvány meghatározott részében és más ilyen, a jellemzőkkel foglalkozó közzétett légiforgalmi tájékoztatásokban megadottnak kell lenni.

5.2.1.3 *Szavak betűzése a rádió-távbeszélő összeköttetések során.* Amikor a rádió-távbeszélő összeköttetés során kétes helyesírású tulajdonneveket, szolgálati rövidítéseket, vagy szavakat kell betűzni, akkor erre az 5-1. ábrán található ABC-t kell használni.

1. Megjegyzés. - Az ABC-ben található szavak, valamint a számok kiejtése a beszélő anyanyelvi szokásaitól függően változhat. A kiejtési változatok túlzott eltérésének kiküszöbölése érdekében az ICAO-tól beszerezhető a kívánatos kiejtést szemléltető poszter.

2. Megjegyzés. - Az 5.2.1.3 pontban részletesen leírt Kiejtési ABC használatát írják elő a Tengerészeti Mozgó Szolgálatnál is. (ITU Rádió Szabályzat, S14-es Függelék).

5.2.1.4 *Számok továbbítása rádió-távbeszélő összeköttetések során*

5.2.1.4.1 *Számok továbbítása*

5.2.1.4.1.1 Minden számot, kivéve az 5.2.1.4.1.2 pontban felsoroltakat, úgy kell továbbítani, hogy minden egyes számjegyet külön kell kimondani.

Megjegyzés. - Az alábbi példák ennek az eljárásnak az alkalmazását mutatják be (a kiejtést lásd az

5.2.1.4.3.1 pontban).

légijármű-hívójelek (aircraft call sign)	*továbbításuk*
CCA 238	Air China **two three eight**
OAL 242	Olympic **two four two**
repülési szintek (flight levels)	*továbbításuk*
FL 180	flight level **one eight zero**
FL200	flight level **two zero zero**
géptengely-irányszögek (headings)	*továbbításuk*
100 fok	heading **one zero zero**
080 fok	heading **zero eight zero**
szélirány és szélsebesség (wind direction and speed)	*továbbításuk*
200 fokról 70 csomó	wind **two zero zero** degrees, **seven zero** knots
160 fokról 18 csomó, szél-lökés 30 csomó	wind **one six zero** degrees, **one eight** knots, gusting **three zero**
transzponder-kódok (transponder codes)	*továbbításuk*
2 400	squawk **two four zero zero**
4 203	squawk **four two zero three**
futópálya (runway)	*továbbítása*
27	runway **two seven**
30	runway **three zero**
magasságmérő-beállítás (altimeter settings)	*továbbítása*
1010	QNH **one zero one zero**
1000	QNH **one zero zero zero**

5.2.1.4.1.2 A tengerszint feletti magasság (altitude), felhőalap, látástávolság és futópálya-menti látástávolság (RVR) értékek továbbítása során, ha a szám egész százasokat vagy ezreseket tartalmaz, akkor a százasok vagy ezresek számát számjegyenként ki kell mondani, amelyet a HUNDRED vagy THOUSAND szó követ értelemszerűen. Ha a számban ezresek és egész százasok kombinációja található, akkor az ezresek számában minden számjegyet külön ki kell mondani, amelyet a THOUSAND szó követ, majd ezután következik a százasok száma és a HUNDRED szó.

Megjegyzés.- A következő példák ennek az eljárásnak az alkalmazását mutatják be (lásd 5.2.1.4.3.1 a kiejtésre vonatkozóan).

Betű	*Szó*	*Közelítő kiejtés*	
		Nemzetközi fonetikai jelekkel	*Latin ABC szerint (angol kiejtési szokások szerint) leírva*
A	Alfa	'ælfa	AL FAH
B	Bravo	'bra:'vo	BRAH VOH
C	Charlie	'tʃa:li *vagy* 'ʃa:li	CHAR LEE v*agy* SHAR LEE
D	Delta	'delta	DELL TAH
E	Echo	'eko	ECK OH
F	Foxtrot	'fɔkstrɔt	FOKS TROT
G	Golf	gɔlf	GOLF
H	Hotel	ho:'tel	HO TELL
I	India	'indi a	IN DEE AH
J	Juliett	'dʒu:li 'et	JEW LEE ETT
K	Kilo	'ki:lo	KEY LOH
L	Lima	'li:ma	LEE MAH
M	Mike	maik	MIKE
N	November	no'vembə	NO VEM BER
O	Oscar	'ɔska	OSS CAH
P	Papa	pə'pa	PAH PAH
Q	Quebec	ke'bek	KEH BECK
R	Romeo	'ro:mi o	ROW ME OH
S	Sierra	si'era	SEE AIR RAH
T	Tango	'tængo	TANG GO
U	Uniform	'ju:nifɔ:m *vagy* 'u:nifɔrm	YOU NEE FORM vagy OO NEE FORM
V	Victor	'vikta	VIK TAH
W	Whiskey	'wiski	WISS KEY
X	X-ray	'eks'rei	ECKS RAY
Y	Yankee	'jænki	YANG KEY
Z	Zulu	'zu:lu:	ZOO LOO

Megjegyzés. - A latin ABC használatának megközelítő bemutatásához a szótagok hangsúlyozása aláhúzásra került.

5-1. ábra: A rádió-távbeszélő betűzési ABC (lásd az 5.2.1.3 pontot)

1. Megjegyzés. - Az ABC-ben található szavak kiejtése a beszélő anyanyelvi szokásaitól függően változhat. A kiejtési változatok túlzott eltérésének kiküszöbölése érdekében, az ICAO-tól beszerezhető a kívánatos kiejtést szemléltető poszter.

2. Megjegyzés. - Az 5.2.1.3 pontban részletesen leírt Kiejtési ABC használatát írják elő a Tengerészeti Mozgó Szolgálatnál is. (ITU Rádió Szabályzat, S14-es Függelék).

tengerszint feletti magasság (altitude)	*továbbításuk*
800	**eight hundred**
3 400	**three thousand four hundred**
12 000	**one two thousand**

felhőalap (cloud height)	*továbbításuk*
2 200	**two thousand two hundred**
4 300	**four thousand three hundred**
látástávolság (visibility)	*továbbításuk*
1 000	visibility **one thousand**
700	visibility **seven hundred**
futópálya menti látástávolság (runway visual range)	*továbbításuk*
600	RVR **six hundred**
1 700	RVR **one thousand seven hundred**

5.2.1.4.1.3 A tizedespontot tartalmazó számokat az 5.2.1.4.1.1 pontban található szabályok szerint kell továbbítani, úgy, hogy a tizedespontot a megfelelő sorrendet betartva a "DECIMAL" (TIZEDES) szóval kell jelölni.

1. Megjegyzés. - Az alábbi példák ennek az eljárásnak az alkalmazását mutatják be:

Szám	*Továbbítás módja*
100.3	ONE ZERO ZERO DECIMAL THREE
38 143.9	THREE EIGHT ONE FOUR THREE DECIMAL NINE

2. Megjegyzés. - A VHF frekvenciák azonosítására a tizedespont után használt számjegyek számát a csatorna-osztás határozza meg (a 25 kHz-es osztással elválasztott frekvenciákra az 5.2.1.7.3.4.3 pont, illetve a 8,33 kHz-es osztással elválasztott frekvenciákra pedig az 5.2.1.7.3.4.4 pont előírásai vonatkoznak).

3. Megjegyzés. - A 8.33 kHz-es és a 25 kHz-es osztáshoz tartozó csatorna-osztási / frekvencia párosítási kapcsolatokat az V. kötet 4.1 (bis) táblázata foglalja össze.

5.2.1.4.1.4 **PANS. -** *Időadat továbbításakor általában csak az óra perceit szükséges megadni. Minden egyes számjegyet külön kell kimondani. Az órát is közölni kell azonban, ha annak elhagyása bármilyen zavart okozhatna.*

Megjegyzés. - Az alábbi példák ennek az eljárásnak az alkalmazását mutatják be, amennyiben az 5.2.1.2.2 pont előírásait alkalmazzák:

Idő	*Továbbítása*	
0920	*(de. 9:20)*	TOO ZE-RO, v*agy* ZE-RO NIN-er TOO ZE-RO
1643	*(du.. 4:43)*	FOW-er TREE, vagy WUN SIX FOW-er TREE

5.2.1.4.2 *Számok ellenőrzése, megerősítése*

5.2.1.4.2.1 Ha szükséges a számok pontos vételének ellenőrzése, megerősítése, akkor a közleményt továbbító személy felkéri a közleményt vevő személyt a számok visszaolvasására.

5.2.1.4.3 *Számok kiejtése*

5.2.1.4.3.1 Az 5.2.1.2.2 pont előírásainak alkalmazása során a számokat az alábbi kiejtéssel kell továbbítani:

Szám, vagy közlemény számrésze	*Kiejtés (angol kiejtési megfeleltetéssel)*
0	ZE-RO
1	WUN
2	TOO
3	TREE
4	FOW-er
5	FIFE
6	SIX
7	SEV-en
8	AIT
9	NIN-er
Decimal	DAY-SEE-MAL
Hundred	HUN-dred
Thousand	TOU-SAND

Megjegyzés. - A fenti táblázatban a nagybetűvel írt szótagok a hangsúlyosak. Például, a ZE-RO szóban mindkét szótag egyformán hangsúlyos, míg a FOW-er szóban a hangsúly az első szótagra esik.

5.2.1.5 *Adás-technika*

5.2.1.5.1 **PANS**. - *Minden írott közleményt az adás megkezdése előtt lehetőség szerint egyszer végig kell olvasni, hogy elkerülhető legyen a fölösleges késedelem a továbbítás során.*

5.2.1.5.2 A közleményt adó fogalmazzon tömören, normál társalgási hanghordozást használva.

Megjegyzés. – Lásd a nyelvismereti követelményeket az Annex 1-hez tartozó Függelékben.

5.2.1.5.3 **PANS. -** *A beszéd adás-technikája lehetőség szerint olyan legyen, hogy biztosítsa minden adás során az elérhető legtisztább érthetőségét. Ennek a célnak az elérése érdekében szükséges, hogy a hajózó és a földi személyzet lehetőleg:*
a) minden szót tisztán és világosan ejtsen ki;
b) egyenletes tempóban beszéljen, a beszéd sebessége ne haladja meg a 100 szót percenként. Ha a közlemény légijárműnek szól és a tartalmát le kell írni, akkor beszéljen lassabban, hogy legyen elég idő a közlemény leírására. A számok előtti és utáni kis szünet elősegítheti azok megértését;
c) tartsa a beszéd hangerejét állandó szinten;
d) ismerje a mikrofon-kezelési technikát, különösen azt, hogy a mikrofont állandó távolságban tartsa a szájától, ha nem alkalmaznak állandó hangerőt beállító áramkört;
e) ha szüksges az, hogy elfordítsa a fejét a mikrofontól, átmenetileg függessze fel a beszédet.

5.2.1.5.4 **Ajánlás**.- *A beszéd- és adás-technikát lehetőleg az adás idején uralkodó körülményekhez kell igazítani.*

5.2.1.5.5 **PANS. -** *A továbbításra elfogadott közleményeket lehetőség szerint vagy jól érthető szövegként, vagy jóváhagyott szakkifejezések használatával kell továbbítani anélkül, hogy a közlemény értelmét bármilyen módon megváltoztatnák. A közlemény szövegében előforduló, elfogadott ICAO rövidítéseket általában azokkal a nem-rövidített szavakkal vagy kifejezésekkel ajánlott helyettesíteni, melyeket ezek a rövidítések a továbbításra használt nyelven jelentenek, kivéve azokat a rövidítéseket, amelyeket a gyakori és általános használat következtében a légiközlekedés szakszemélyzete rendszerint megért.*

Megjegyzés. - A PANS-ABC (Doc 8400) kiadvány rövidítéseket kódoló része külön is jelzi azokat a rövidítéseket, amelyek a fenti 5.2.1.5.5 pontban említett kivételek közé tartoznak.

5.2.1.5.6 **PANS. -** *Az összeköttetés meggyorsítása céljából a fonetikus betűzést el lehet hagyni, ha ez nem veszélyezteti a közlemény pontos vételét és érthetőségét.*

5.2.1.5.7 **PANS. -** *Hosszú közlemények továbbításakor, az adást lehetőleg időről időre meg kell szakítani néhány pillanatra, hogy a közleményt adó személy meggyőződhessen arról, hogy a használt frekvencián nincs zavarás, és ezzel lehetőséget adjon a vevő személynek arra, hogyha szükséges, a közlemény nem vett részeinek ismétlését kérhesse.*

5.2.1.5.8 Szükség szerint az alábbi szavakat és kifejezéseket kell használni a rádió-távbeszélő összeköttetések során, a táblázatban megadott jelentés szerint:

Kifejezés	*Jelentés*
ACKNOWLEDGE	"Tudassa velem, hogy vette és megértette ezt a közleményt!"
AFFIRM	"Igen."
APPROVED	"A tervezett tevékenységre az engedély megadva."
BREAK	"Jelzem a közlemény egyes részei közötti elválasztást." *(Akkor kell használni, ha nem különülnek el világosan a szöveg és a közlemény egyéb részei.)*
BREAK BREAK	"Jelzem, hogy itt van a különböző légijárműveknek szóló közlemények közötti elválasztás a frekvencia nagy terhelése miatt."
CANCEL	"Vegye semmisnek a korábban kiadott engedélyt!"
CHECK	"Ellenőrizzen egy rendszert vagy eljárást!" *(Más jelentésben ne használja. Általában nem várnak rá választ.)*
CLEARED	"Felhatalmazom, hogy a megadott feltételek szerint járjon el."
CONFIRM	"Kérem a következők megerősítését: *(engedély, utasítás, rendelkezés, információ)*."
CONTACT	"Létesítsen összeköttetést ... -val."
CORRECT	"Helyes", vagy "Pontos".
CORRECTION	"Hiba történt ebben az adásban *(vagy* a jelzett közleményben). A helyes változat a következő: ...."
DISREGARD	"Ne vegye figyelembe!"

GO AHEAD	"Jöhet a közleménye." *Megjegyzés.- Nem használandó, ha fennáll annak a veszélye, hogy a "GO AHAED" ("FOLYTASSA")* *kifejezést a légijármű tévesen továbbhaladásra való felhatalmazásként értelmezhetné. A "GO* *AHAED" kifejezés kihagyható, és a helyette használt válasz a hívó légiforgalmi állomás hívójeléből,* *és azt követően a válaszoló légiforgalmi állomás hívójeléből álljon.*
HOW DO YOU READ	"Milyen az adásom érthetősége?"*(lásd az* 5.2.1.8.4 *pontot).*
I SAY AGAIN	"Ismétlem az érthetőség, vagy a nyomatékosítás érdekében"
MAINTAIN	"Folytassa a meghatározott körülmény(ek)nek megfelelő módon", vagy szó szerinti értelmében, pl. "Maintain VFR" ("Folytassa VFR szabályok szerint").
MONITOR	"Figyeljen a ... (frekvencián)."
NEGATIVE	"Nem" *vagy* "Nincs engedélyezve." *vagy* "Ez nem helyes." *vagy* "Nem alkalmas."
OVER	"A közleményemnek vége, választ várok Öntől." *(Megjegyzés.- VHF csatornákon általában* *nem használatos.)*
OUT	"Ezt a közleményváltást befejeztem, választ nem várok." *(Megjegyzés: VHF csatornákon* *általában nem használatos.)*
READ BACK	"Ismételje meg a teljes közleményt, vagy annak meghatározott részét, pontosan úgy, ahogyan azt vette!"
RECLEARED	"Az utoljára kiadott engedélyében változás történt, és ez az új engedély hatálytalanítja a korábbi engedélyt vagy annak egy részét."
REPORT	"Jelentse nekem a következő információkat ..."
REQUEST	"Szeretném tudni..." *vagy* "Szeretném megszerezni (megkapni) az ..."
ROGER	"Teljes egészében vettem az utolsó közleményét." *Megjegyzés. - Semmilyen körülmények között sem szabad válaszul olyan közleményekre használni,* *amelyek visszaolvasást (READ BACK) igényelnek, vagy közvetlen megerősítő (AFFIRM), vagy* *elutasító (NEGATIVE) választ.*
SAY AGAIN	"Ismételje meg a teljes utolsó adását, vagy az alábbi részét!"
SPEAK SLOWER	"Csökkentse a beszéd sebességét." *(Megjegyzés: A normál beszédsebességet lásd az 5.2.1.5.3 b) pontban.)*
STANDBY	"Várjon, hívni fogom." *Megjegyzés.- A hívó fél rendszerint ismét megpróbálja a kapcsolat felvételét, ha a késedelem* *hosszúra nyúlik. A STANDBY nem egy jóváhagyás, vagy visszautasítás.*

UNABLE "Nem tudom teljesíteni a kérését, utasítását, vagy engedélyét."
Megjegyzés. - Az UNABLE kifejezés után általában közölni szokták az okot is.

WILCO *(A "will comply" kifejezés rövidítése.)*
"Megértettem a közleményét, és az abban foglaltaknak megfelelően fogok eljárni."

WORDS TWICE a) *Kérésként:* "A kommunikáció (ti. vétel) nehézségekbe ütközik. Kérem, minden szót, vagy
szócsoportot adjon kétszer!"
b) *Információként:* "Mivel az adás nehézségekbe ütközik, ezért ebben a közleményben minden
szót vagy szócsoportot kétszer adok."

5.2.1.6 *Közlemények összeállítása*

5.2.1.6.1 Azoknak a közleményeknek, amelyeket kizárólag a légiforgalmi mozgó szolgálat kezel, az alábbi részekből kell állnia, az itt leírt sorrendben:
a) hívás, amely tartalmazza a címzettet és a feladót (*lásd* az 5.2.1.7.3 pontot);
b) szöveg (*lásd* az 5.2.1.6.2.1.1 pontot).

Megjegyzés.- Az alábbi példák ennek az eljárásnak az alkalmazását mutatják be:

(hívás) NEW YORK RADIO SWISSAIR ONE ONE ZERO
(szöveg) REQUEST SELCAL CHECK ("SELCAL ellenőrzést kérek!"), vagy
(hívás) SWISSAIR ONE ONE ZERO NEW YORK RADIO
(szöveg) CONTACT SAN JUAN ON FIVE SIX ("Lépjen összeköttetésbe ..... ").

5.2.1.6.2 Azokat a közleményeket, melyeket a továbbítás során részben AFTN-en keresztül is kell kezelni, valamint hasonlóképpen azokat a közleményeket, melyeket nem az előre meghatározott szétosztási rendnek megfelelő módon kezelnek (*lásd* a 3.3.7.1 pontot), az alábbiak szerint kell összeállítani:

5.2.1.6.2.1 *Ha egy légijármű a feladója :*
1) hívás (lásd az 5.2.1.7.3 pontban);
2) a "FOR" szó;
3) a címzett szervezet neve;
4) a célállomás neve;
5) a szöveg.

5.2.1.6.2.1.1 A szöveg a lehető legrövidebb formában tartalmazza a szükséges információkat; teljes mértékben ki kell használni az ICAO kifejezéseket.

Megjegyzés. - Az alábbi példa ennek az eljárásnak az alkalmazását mutatja be:

(hívás) BOSTON RADIO SWISSAIR ONE TWO EIGHT

(címzés) FOR SWISSAIR BOSTON

(szöveg) NUMBER ONE ENGINE CHANGE REQUIRED (Az egyes számú hajtómű cseréje szükséges)

5.2.1.6.2.2 *Ha a közleményt egy légijárműnek címezik:* Ha egy, a 4.4.2 pont előírásai szerint összeállított közleményt egy légiforgalmi állomás közvetít egy, a levegőben repülésben lévő légijármű számára, akkor a közleménynek a légiforgalmi mozgó szolgálat segítségével történő továbbítása során az AFTN közlemény-formátum fej-részét és címzését el kell hagyni.

5.2.1.6.2.2.1 Amikor az 5.2.1.6.2.2 pont előírásait alkalmazzák, a légiforgalmi mozgó szolgálat közleménye az alábbi részeket kell, hogy magában foglalja:
a) a szöveget [beleértve az AFTN közleményben található minden helyesbítést (COR) is];
b) a "FROM" szót;
c) a feladó szervezet nevét és a feladás helyét (az AFTN közlemény feladó-részéből átvéve).

5.2.1.6.2.2.2 **PANS.** .- *Ha a légiforgalmi állomás által egy repülésben lévő légijárműnek továbbítandó közleményben elfogadott ICAO rövidítések vannak, akkor a közlemény továbbítása során ezeket általában azokkal a nem-rövidített szavakkal vagy kifejezésekkel ajánlott helyettesíteni, melyeket ezek a rövidítések a továbbításra használt nyelven jelentenek, kivéve azokat a rövidítéseket, amelyeket a gyakori és általános használat következtében a légiközlekedés szakszemélyzete rendszerint megért.*

Megjegyzés. - Az 5.2.1.6.2.2.2 pontban említett kivételeket képező rövidítések a PANS-ABC (Doc 8400) rövidítések kdolási részében vannak külön meghatározva.

5.2.1.7 *Hívás*

5.2.1.7.1 R*ádió-távbeszélő hívójelek légiforgalmi állomások számára*

Megjegyzés. - A hívójelek összeállítási szabályait az ITU S19 Rádió Szabályzatának III. és VII. Része tartalmazza.

5.2.1.7.1.1 A légiforgalmi mozgó szolgálat keretein belül a légiforgalmi állomásokat az alábbiakkal kell azonosítani:
a) a hely nevével; és
b) a rendelkezésre álló egység vagy szolgálat megjelölésével.

5.2.1.7.1.2 Az egységet vagy szolgálatot az alábbi táblázat alapján kell azonosítani, azzal a kivétellel, hogy a hely, vagy az egység/szolgálat nevét el lehet hagyni, feltéve, hogy már kielégítő összeköttetést sikerült létesíteni.

Egység/szolgáltatás megjelölése	*Hívójel utótag*
Körzeti irányító központ	CONTROL
Bevezető irányítás	APPROACH
Bevezető radar-irányítás érkezőknek	ARRIVAL
Bevezető radar-irányítás indulóknak	DEPARTURE
Repülőtéri irányítás	TOWER
Gurító irányítás	GROUND
Radar-irányítás (általában)	RADAR
Precíziós bevezető- radar-irányítás	PRECISION
Iránymérő állomás	HOMER
Repülés-tájékoztató szolgálat	INFORMATION
Engedély-kiadás	DELIVERY
Előtéri irányítás	APRON
Társasági diszpécser	DISPATCH
Légiforgalmi állomás	RADIO

5.2.1.7.2 A légijárművek rádió-távbeszélő hívójelei

5.2.1.7.2.1 *Teljes hívójelek*

5.2.1.7.2.1.1 Egy légijármű rádió-távbeszélő hívójele az alábbi típusok valamelyike kell , hogy legyen:
a) típusú – a karakterek megegyeznek a légijármű lajstromjelével; vagy
b) típusú – a légijármű járatójának rádió-távbeszélő megjelölése, amelyet a légijármű lajstromjelének utolsó négy karaktere követ;
c) típusú – a légijármű járatójának rádió-távbeszélő megjelölése, amelyet a járatot azonosító jelzés követ.

1. Megjegyzés. - A fenti a) típusú hívójelben használható előtag lehet a légijármű gyártójának neve vagy modelljének neve (lásd az 5.1 táblázatot).

2. Megjegyzés. - A b) és c) típusú rádió-távbeszélő azonosítókat a Doc 8585, Légijármű Járatók, Légiforgalmi Szervezetek, Hatóságok és Szolgálatok Azonosítói /Designators for Aircraft Operating Agencies, Aeronautical Authorities and Services/ *tartalmazza.*

3. Megjegyzés. - Az előbbiekben felsorolt hívójelek közül bármelyik beírható az ICAO repülési terv 7. rovatába, mint a légijármű azonosítója. A repülési terv kitöltésére vonatkozó útbaigazításokat a PANS-ATM, Doc 4444 tartalmazza.

5.2.1.7.2.2 *Rövidített hívójelek*

5.2.1.7.2.2.1 A légijárművek fenti 5.2.1.7.2.1.1 pontban bemutatott rádió-távbeszélő hívójeleit - a c) típusú hívójel kivételével, - az 5.2.1.7.3.3.1 pontban leírt feltételekkel le lehet rövidíteni. A rövidített hívójeleknek az alábbi formátumúaknak kelllenniük:
a) típusú – a lajstromjel első karaktere és legalább a hívójel utolsó két karaktere; vagy
b) típusú – a légijármű járatójának rádió-távbeszélő megjelölése és legalább a hívójel utolsó két karaktere;

5-1. táblázat: Példák teljes és rövidített hívójelekre

(lásd az 5.2.1.7.2.1 és az 5.2.1.7.2.2 pontokat)

		a) típus		b) típus	c) típus
Teljes hívójel	N 57826	*CESSNA FABCD	*CITATION FABCD	VARIG PVMA	SCANDINAVIAN 937
Rövidített hívójel	N26	CESSNA CD	CITATION CD	VARIG MA	(nem rövidíthető)
	vagy	vagy	vagy	vagy	
	N826	CESSNA BCD	CITATION BCD	VARIG VMA	

* Ezek a példák az 5.2.1.7.2.1.1 pont 1. Megjegyzésében található előírások alkalmazását mutatják be.

c) típusú – nem rövidíthető formátum.

Megjegyzés.- A fenti a) típusú hívójelben az első karakter helyett akár a légijármű gyártójának, akár a légijármű modelljének neve használható.

5.2.1.7.3 *Rádió-távbeszélő eljárások*

5.2.1.7.3.1 A légijármű a rádió-távbeszélő hívójelének típusát repülés közben nem változtathatja meg, kivéve ha erre - ideiglenes jelleggel - egy légiforgalmi irányító egység a repülés biztonsága érdekében utasítja.

5.2.1.7.3.1.1 Hacsak nem a repülés biztonsága érdekében szükséges, a légijárműhöz felszállása közben, a végső megközelítés utolsó fázisában és a leszállás utáni kifutás közben nem szabad közleményt intézni.

5.2.1.7.3.2 *Rádió-távbeszélő összeköttetés létesítése*

5.2.1.7.3.2.1 Az összeköttetés felvételekor mindig a teljes rádió-távbeszélő hívójelet kell használni. Az összeköttetést létesítő légijárműnek a hívást az 5-2. táblázatban foglaltak szerint kell végrehajtania.

5.2.1.7.3.2.2 **PANS**. - *Azoknak az állomásoknak, melyeknek egy közleményt valamennyi olyan állomás számára kell továbbítaniuk, amelyek azt valószínűleg hallani fogják, az ilyen adást lehetőleg az "ALL STATIONS" ("MINDEN ÁLLOMÁSNAK") általános hívással kell kezdeniük, amelyet a hívó állomás azonosítója kell, hogy kövessen.*

Megjegyzés. - Az ilyen általános hívásokra nem várnak választ, kivéve, ha ezt követően az egyes állomásokat fel nem kérik a nyugtázásra.

5.2.1.7.3.2.3 Az előbbi hívásokra az 5-3. táblázatnak megfelelően kell válaszolni.

5.2.1.7.3.2.4 **PANS. -** *Ha egy állomás hívást vett, de nem biztos a hívó állomás azonosítójában, akkor lehetőleg az alábbiak adásával válaszoljon.*

STATION CALLING . . . (*a meghívott állomás neve*), SAY AGAIN YOUR CALL SIGN ("Ismételje a hívójelét!").

Megjegyzés. - Az alábbi példa ennek az eljárásnak az alkalmazását mutatja be:
(CAIRO állomás válasza)
STATION CALLING CAIRO *(szünet)* SAY AGAIN YOUR CALL SIGN
/"A Kairó-t hívó állomásnak. *(szünet)* Ismételje meg a hívójelét!"/

5.2.1.7.3.2.5 A közlemény-váltást egy hívással és egy válasz-adással kell kezdeni, amikor az összeköttetést szeretnék létrehozni, kivéve, ha bizonyosak abban, hogy a hívott állomás venni fogja a hívást; ebben az esetben a hívó állomás leadhatja a közleményét anélkül, hogy megvárná a hívott állomás jelentkezését.

5.2.1.7.3.2.6 A légijárművezetők közötti, levegő-levegő közlemény-váltást a 123,45 MHz-es csatornán kell kezdeményezni, akár egy meghatározott légijármű állomásnak szóló közvetlen hívással, vagy általános hívással, figyelembe véve ezen csatorna használatának feltételeit.

Megjegyzés. - A levegő-levegő csatornák használatának feltételeit lásd az Annex 10, V. Kötet, 4.1.3.2.1 pontban, valamint a II. Kötet, 5.2.2.1.1.4 pontban.

5.2.1.7.3.2.6.1 **PANS .-** *Mivel a légijármű egynél több frekvencián is figyelhet, a kezdeti hívás lehetőleg tartalmazza a csatorna megkülönböztető "INTERPILOT" megjelölését.*

Megjegyzés. - Az alábbi példák ezen hívási eljárások alkalmazását mutatják be:

CLIPPER123 – SABENA901 – INTERPILOT – DO YOU READ
("CLIPPER123 – A SABENA901 hívja az INTERPILOT csatornán – hallja az adásomat?"), *vagy*

ANY AIRCRAFT VICINITY OF 30 NORTH 160 EAST - JAPANAIR 401 - INTERPILOT – OVER
("Bármely légijármű az Északi szélesség 30 és a Keleti hosszúság 160 körzetében – a JAPANAIR 401 hívja az INTERPILOT csatornán – Vétel")

5-2. táblázat: Rádió-távbeszélő hívási eljárások*

(lásd az 5.2.1.7.3.2.1 p*ontot)*

	a) típus	*b) típus*	*c) típus*
A hívott állomás megnevezése	NEW YORK RADIO	NEW YORK RADIO	NEW YORK RADIO
A hívó állomás megnevezése	GABCD**	SPEEDBIRD ABCD**	AEROFLOT321**

** Bizonyos esetekben, amikor a hívást a légiforgalmi állomás kezdeményezi, a hívást kódolt impulzus-jelek leadásával is végre lehet hajtani.*

*** A rádió-távbeszélő hívójel és a légijármű típusa kivételével a hívójel minden karakterét külön ki kell mondani. Az egyes betűket az 5.2.1.3 pontban előírt rádió-távbeszélő ABC szerint kell kiejteni. A számokat az 5.2.1.4 pont előírásai szerint kell kimondani.*

5-3. táblázat: Rádió-távbeszélő eljárások válasz esetére

(lásd az 5.2.1.7.3.2.3 *pontot)*

	a) típus	*b) típus*	*c) típus*
A hívott állomás megnevezése	GABCD*	SPEEDBIRD ABCD*	AEROFLOT321*
A válaszoló állomás megnevezése	NEW YORK RADIO	NEW YORK RADIO	NEW YORK RADIO
Felkérés az adás folytatására	GO AHEAD	GO AHEAD	GO AHEAD

** A rádiótávbeszélő megjelölés és a légijármű típusa kivételével a hívójel minden karakterét külön ki kell mondani. Az egyes betűket az 5.2.1.3 pontban előírt rádiótávbeszélő ABC szerint kell kiejteni. A számokat az 5.2.1.4 pont előírásai szerint kell kimondani.*

5.2.1.7.3.3 *A kapcsolat-felvétel utáni rádió-távbeszélő közlemény-váltások*

5.2.1.7.3.3.1 A fenti 5.2.1.7.2.2 pontban leírt rövidített rádió-távbeszélő hívójeleket csak akkor szabad használni, ha már sikeres összeköttetést sikerült létrehozni, és ha hívójel összetévesztés bekövetkezése nem valószínű. A légijármű állomásnak csak akkor szabad a rövidített hívójelét használnia, ha a légiforgalmi állomás már intézett hozzá hívást ilyen módon.

5.2.1.7.3.3.2 Az összeköttetés létrehozása után a folyamatos kétirányú kommunikáció engedélyezett minden további azonosítás, vagy hívás nélkül, a közlemény-váltás befejezéséig.

5.2.1.7.3.3.3 Az esetleges összetévesztés elkerülése érdekében, amikor ATC engedélyeket adnak ki, valamint az ilyen engedélyek visszaolvasásakor, a légiforgalmi irányítók és a légijárművezetők mindig kötelesek hozzátenni annak a légijárműnek a hívójelét, amelyre az adott engedély vonatkozik.

5.2.1.7.3.4 *Az adó frekvencia azonosítása, jelölése*

5.2.1.7.3.4.1 **PANS. -** *Mivel a légiforgalmi állomás kezelője általában több frekvencián figyel, a hívás után lehetőleg azonosítania kell a használt frekvenciát, hacsak nincs egyéb ismert, megfelelő módszer a frekvencia azonosítására.*

5.2.1.7.3.4.2 **PANS. -** *Ha nem valószínű, hogy összetévesztheti, akkor a HF csatornák azonosításakor az első két számjegyet kell megadni (kHz-ben) az adó csatorna azonosítására.*

Megjegyzés. - Az alábbi példa ennek az eljárásnak az alkalmazását mutatja be:

(PAA 325 hívja Kingstont a 8871 kHz-es frekvencián)
KINGSTON CLIPPER THREE TWO FIVE - ON EIGHT EIGHT

5.2.1.7.3.4.3 **PANS. -** *Ha a VHF kommunikációs csatornákat 25 kHz-es osztással választják el egymástól, a rádió-távbeszélő közlemény-váltások során az adó vivőfrekvencia azonosítására csak az első 5 számjegy használata szükséges. A tizedespont után csak két fontos számjegyet kell használni. Ha itt két nulla áll, akkor egy nulla számít fontos számjegynek.*

Megjegyzés. - Az alábbi példa ennek az eljárásnak az alkalmazását mutatja be:

Csatorna	*Továbbítása*
118.000	*ONE ONE EIGHT DECIMAL ZERO*
118.025	*ONE ONE EIGHT DECIMAL ZERO TWO*

5.2.1.7.3.4.4 **PANS. -** *Amennyiben a VHF összeköttetési csatornákat 8.33 kHz-es osztással választják el egymástól a rádió-távbeszélő közlemény-váltások során, az adásra használt frekvencia azonosítójának lehetőleg mind a 6 számjegyét használni kell. A tizedespont után az összes csatorna számára három számjegyet kell használni.*

1. Megjegyzés. - Az alábbi példák ennek az eljárásnak az alkalmazását mutatják be:

Csatorna	*Továbbítása*
118.005	*ONE ONE EIGHT DECIMAL ZERO ZERO FIVE*
118.010	*ONE ONE EIGHT DECIMAL ZERO ONE ZERO*
118.025	*ONE ONE EIGHT DECIMAL ZERO TWO FIVE*

2. Megjegyzés. - A szám szerinti megjelölés megegyezik az V. kötet 4-1. (bis) táblázatában felsorolt csatorna-azonosítókkal.

5.2.1.8 *Ellenőrző adások*

5.2.1.8.1 **PANS. -** *Az ellenúrző adásoknak az alábbi formai követelményeknek kell megfelelniük:*
a) a hívott állomás azonosítója;
b) a légijármű azonosító jelzése;
c) a "RADIO CHECK" szavak;
d) a használt frekvencia.

5.2.1.8.2 **PANS. -** *Az ellenőrző adásra adott válasz az alábbiakban közölt kell, hogy legyen:*
a) a légijármű azonosítója;
b) a válaszoló légiforgalmi állomás azonosító jele;
c) a légijármű adásának érthetőségére vonatkozó információk.

5.2.1.8.3 **PANS. -** *Az ellenőrző adást és az arra adott választ a légiforgalmi állomáson rögzíteni kell.*

5.2.1.8.4 **PANS. -** *Amikor az ellenőrzést elvégezték, akkor az alábbiaknak megfelelő érthetőségi fokozat szerint kell értékelni azt.*
Érthetőségi fokozatok
1 Érthetetlen
2 Szakadozottan érthető
3 Érthető, de csak nehézségekkel
4 Érthető
5 Tökéletesen érthető

5.2.1.9 *Közlemény-váltás*

5.2.1.9.1 A közlemény-váltásnak tömörnek és egyértelműnek kell lennie, ahol lehetséges, a szabványos szakmai kifejezések használatával.

5.2.1.9.1.1 **Ajánlás. -** *A rövidítési eljárásokat lehetőleg csak akkor kell használni, ha már az összeköttetést létrehozták, és ahol nem valószínű, hogy ez összetévesztést okozhat.*

5.2.1.9.2 *A vétel nyugtázása.* A vevő állomás kezelőjének meg kell győződnie arról, hogy a közleményt pontosan vette, mielőtt a vételt nyugtázná.

Megjegyzés. - A vétel nyugtázását nem szabad összetéveszteni a rádió távközlési hálózat üzemi tevékenységeibe való bekapcsolódás igazolásával.

5.2.1.9.2.1 Ha egy közlemény vételének nyugtázását egy légijármű-állomás továbbítja, akkor a nyugtázó közlemény a légijármű hívójeléből áll.

5.2.1.9.2.2 **PANS. -** *A légijármű-állomás a légiforgalmi irányítás fontos (lényeges) közleményeinek, vagy azok bizonyos részeinek vételét lehetőleg visszaolvasással igazolja/nyugtázza, majd a visszaolvasást a saját rádió-hívójelével fejezze be!*

1. Megjegyzés. - A visszaolvasási kötelezettség alá eső légiforgalmi irányítói engedélyeket, utasításokat és tájékoztatásokat a PANS-ATM (Doc 4444) határozza meg.

2. Megjegyzés. - Az alábbi példák ennek az eljárásnak az alkalmazását mutatják be:
(ATC engedély egy légijármű számára a hálózat egyik állomásától):
Állomás:
TWA NINE SIX THREE MADRID
Légijármű:
MADRID TWA NINE SIX THREE - GO AHEAD
Állomás:
TWA NINE SIX THREE MADRID - ATC CLEARS
TWA NINE SIX THREE TO DESCEND TO NINE THOUSAND FEET

Légijármű (nyugtázza a közleményt):
CLEARED TO DESCEND TO NINE THOUSAND FEET - TWA NINE SIX THREE

Állomás (jelzi a visszaolvasás pontosságát):
MADRID

5.2.1.9.2.3 Ha egy közlemény vételének nyugtázását egy légiforgalmi állomás továbbítja:
1) egy légijármű-állomás felé: a nyugtázás a légijármű hívójeléből áll, amelyet, amennyiben szükségesnek ítélik, ki lehet egészíteni a légiforgalmi állomás hívójelével;
2) egy másik légiforgalmi állomás felé: a nyugtázás a közleményt nyugtázó légiforgalmi állomás hívójeléből kell, hogy álljon.

5.2.1.9.2.3.1 **PANS.-** *A légiforgalmi állomásnak a helyzet-jelentéseket és egyéb, a repülés előrehaladásával kapcsolatos közleményeket úgy kell nyugtáznia, hogy visszaolvassa a jelentést és a visszaolvasást a saját hívójelével zárja, kivéve, hogy a visszaolvasási eljárást ideiglenesen fel lehet függeszteni, valahányszor ez enyhíti a közleményváltásra használt csatorna zsúfoltságát.*

5.2.1.9.2.4 **PANS.** - *Ellenőrzés céljából megengedhető kell, hogy legyen az, hogy a vevő állomás magát a közleményt is visszaolvassa, mintegy a vétel kiegészítő nyugtázásaként. Ilyen esetekben annak az állomásnak, amelynek a közleményt visszaolvasták, a saját hívójele leadásával kell nyugtáznia a visszaolvasás helyességét.*

5.2.1.9.2.5 **PANS.** - *Ha ugyanabban a közleményben helyzet-jelentés és egyéb tájékoztatás (pl. időjárás- jelentés) is található, a tájékoztatást úgy kell nyugtázni, hogy a helyzet-jelentés visszaolvasása után a "WEATHER RECEIVED" ("IDŐJÁRÁSI TÁJÉKOZTATÁST VETTEM") szavakat kell használni, kivéve, ha a hálózat más állomásainak szükséges a tájékoztatás vétele. Egyéb közleményeket a légiforgalmi állomásnak csak a saját hívójelének közlésével kell nyugtáznia.*

5.2.1.9.3 *A közlemény-váltás befejezése.* A rádió-távbeszélő közlemény-váltást a vevő állomásnak kell befejeznie, a saját hívójele leadásával.

5.2.1.9.4 *Helyesbítések és ismétlések*

5.2.1.9.4.1 Ha az adás során hibát követtek el, akkor a "CORRECTION" szót kell használni, utána meg kell ismételni az utolsó helyesen vett csoportot, vagy kifejezést, majd legvégül le kell adni a szöveg helyes változatát.

5.2.1.9.4.2 Ha egy helyesbítést legjobban a teljes közlemény megismétlésével lehet végrehajtani, a kezelőnek a "CORRECTION, I SAY AGAIN" kifejezést kell használnia, mielőtt a közleményt másodszor is leadná.

5.2.1.9.4.3 **Ajánlás.** - *Ha egy közleményt továbbító kezelő úgy gondolja, hogy annak vétele valószínűleg nehézségekbe fog ütközni, akkor a közlemény fontos elemeit lehetőleg kétszer kell leadnia.*

5.2.1.9.4.4 Ha a vevő állomás kezelője kételkedik az általa vett közlemény helyességében, akkor a közlemény teljes, vagy részleges ismétlését kell kérnie.

5.2.1.9.4.5 Ha a teljes közlemény ismétlésére van szükség, akkor a "SAY AGAIN" szavakat kell használni. Ha a közleménynek csak egy részét kell megismételni, akkor a kezelő a következőket kell, hogy mondja: "SAY AGAIN ALL BEFORE... (az első kielégítően vett szó)"; vagy "SAY AGAIN ... (a hiányzó rész előtti utolsó szó) TO ... (a hiányzó rész utáni első szó)"; vagy "SAY AGAIN ALL AFTER ... (az utolsó kielégítően vett szó)".

5.2.1.9.4.6 **Ajánlás.** - *A közlemény meghatározott elemeinek ismétlését azok megfelelő megnevezésével lehet kérni, például: "SAY AGAIN ALTIMETER" (Ismételje meg a magasságmérő beállítását!), "SAY AGAIN WIND" (Ismételje meg a szelet!).*

5.2.1.9.4.7 Ha a visszaolvasás ellenőrzésekor a kezelő pontatlan elemeket fedez föl, akkor ezt követően a "NEGATIVE I SAY AGAIN" kifejezést kell használnia, majd helyesen meg kell ismételje a kérdéses közlemény elemeket.

5.2.1.9.5 *"Operations normal" ("Normális Üzemi Körülmények") jelentések*

PANS. - *Ha a légijármű "Normális Üzemi Körülmények" jelentést továbbít, akkor a közleménynek az előírt hívásból és az "OPERATIONS NORMAL" szavakból kell állnia.*

5.2.2 Összeköttetés létrehozása és biztosítása

5.2.2.1 *Frekvencia figyelés / Szolgálati idő*

5.2.2.1.1 Repülés közben a légijármű-állomások kötelesek az illetékes Hatóság által előírt módon figyelni, és - a repülés biztonságát érintő okok kivételével - ezt a figyelést nem függeszthetik fel az érintett légiforgalmi állomás(ok) tájékoztatása nélkül.

5.2.2.1.1.1 A hosszú-távú, víz feletti repülést végző, vagy az olyan kijelölt területek felett repülő légijárműveknek, melyek fedélzeten kötelező, hogy kényszerhelyzeti helyjeladó (ELT) legyen, folyamatosan figyelniük kell a 121,5 MHz VHF kényszerhelyzeti frekvencián, kivéve, amikor a légijármű más VHF csatornán éppen forgalmaz, illetve amikor a fedélzeti berendezéseinek jellemzői ezt korlátozzák, vagy a pilótafülkében uralkodó pillanatnyi munka- terhelés nem teszi lehetővé két csatorna egyidejű figyelését.

5.2.2.1.1.2 A légijárműveknek folyamatosan figyelniük kell a 121,5 MHz VHF kényszerhelyzeti frekvencián az olyan körzetekben, vagy útvonalakon, ahol lehetséges a légijármű elfogása, vagy fennáll egyéb veszélyes helyzet lehetősége, és ahol ezt a követelményt az Illetékes Hatóság előírta.

5.2.2.1.1.3 **Ajánlás.**- *Az 5.2.2.1.1.1 és az 5.2.2.1.1.2 pontokban leírt körülményektől eltérő repülések során a légijárműveknek a lehető legteljesebb mértékben figyelniük kell a 121,5 MHz kényszerhelyzeti frekvenciát.*

5.2.2.1.1.4 A levegő-levegő VHF összeköttetési csatorna felhasználójának gondoskodnia kell arról, hogy megfelelő figyelést biztosítson a kijelölt ATS frekvenciákon, a légiforgalmi kényszerhelyzeti csatorna frekvenciáján és minden egyéb kötelezően figyelendő frekvencián.

5.2.2.1.2 A légiforgalmi állomásoknak az Illetékes Hatóság által előírt figyelést kell biztosítaniuk.

5.2.2.1.3 A légiforgalmi állomásoknak az egységek szolgálati ideje alatt folyamatosan figyelniük kell a 121,5 MHz VHF kényszerhelyzeti csatornán, ahol az ehhez szükséges berendezések föl vannak szerelve.

Megjegyzés. - Lásd az Annex 10, V. Kötet, 4.1.3.1.1 pontjában a légiforgalmi állomásokon a 121,5 MHz frekvencia használatával kapcsolatos rendelkezéseket.

5.2.2.1.4 Amikor szükség van arra, hogy egy légijármű-állomás vagy egy légiforgalmi állomás bármilyen okból felfüggessze az üzemelését - ha lehetősége van rá -, akkor értesítenie kell az érintett többi állomást az üzemelés várható újra-kezdési időpontjának megadásával. Amikor az üzemelést újra-kezdi, erről tájékoztatnia kell a többi érintett állomást.

5.2.2.1.4.1 Amikor szükség van arra, hogy az üzemelést az eredeti értesítésben megadott időn túl is felfüggesszék, akkor lehetőség szerint az először közölt időpontban, vagy ahhoz minél közelebb kell leadni az üzemelés újra- kezdésének módosított időpontját.

5.2.2.1.5 **Ajánlás** .- *Ha egy ilégiforgalmi rányító két vagy több ATS frekvenciát is használ egyidőben, akkor fontolóra kell venni olyan átjátszó berendezések biztosítását, amelyekkel a frekvenciák bármelyikén zajló ATS-, valamint légijármű adásokat egyidejűleg le lehet adni a többi használatos frekvencián is, hogy a hatótávolságon belül lévő légijármű-állomások hallhassák a légiforgalmi irányítótól származó és hozzá intézett összes közleményt.*

5.2.2.2 *A hálózati üzemelés alapelvei (HF kommunikáció)*

5.2.2.2.1 **PANS.** - *Egy adott rádió-távbeszélő hálózatba tartozó légiforgalmi állomásoknak segítséget kell nyújtaniuk egymásnak az alábbi hálózati alapelvek szerint, annak érdekében, hogy képesek legyenek a hálózat illetékességi területén belül található repülési útvonalakon közlekedő légijárművek által megkövetelt levegő-föld kommunikációs szolgálat biztosítására.*

5.2.2.2.2 **PANS.** - *Ha a hálózat nagyszámú állomásból áll, a hálózati összeköttetési szolgáltatást bármely meghatározott útvonal-szakaszon repülő légijármű számára azoknak a kiválasztott állomásoknak kell nyújtaniuk, amelyeket az adott útvonal-szakaszra illetékes /kijelölt/ állomásoknak ("regular stations") neveznek.*

1. Megjegyzés. - Egy megadott útvonal-szakaszra az illetékes/kijelölt állomások kiválasztása - ahol szükséges - körzeti vagy helyi megállapodás alapján történik, ha szükséges, a hálózatért felelős Államok között folytatott konzultáció után.

2. Megjegyzés. - Elvileg, az illetékes állomások azok az állomások lesznek, amelyek az adott útvonal-szakaszokon közlekedő légijárművekkel közvetlenül kapcsolatban álló helységeket szolgálják ki, azaz a fel- és leszállási pontokat, a megfelelő repülés-tájékoztató központokat, vagy körzeti irányító központokat, és bizonyos esetekben, egyéb megfelelő helyen telepített állomások is lehetnek, amelyekre a rádiófedés teljessé tételéhez, vagy az adások vételéhez szükség van.

3. Megjegyzés. - Az illetékes állomások kiválasztásakor figyelembe kell venni a használatban lévő frekvenciákon a rádióhullámok terjedési tulajdonságait is.

5.2.2.2.3 **PANS.** - *Olyan területeken, vagy útvonalakon, ahol a rádióhullámok terjedési jellemzői, a repülések útvonalának hossza vagy a légiforgalmi állomások közötti távolság további intézkedéseket tesz szükségessé ahhoz, hogy ilymódon a levegő/föld kommunikáció folyamatosságát a teljes útvonal-szakaszon biztosítsák, az illetékes állomásoknak meg kell osztaniuk egymás között az elsődleges figyelési felelősséget úgy, hogy minden egyes állomás a repülés azon szakaszán nyújtson elsődleges figyelő-szolgálatot, amely szakaszon a légijármű közleményeit a leghatékonyabban képes kezelni.*

5.2.2.2.4 **PANS.** - *Az elsődleges figyelő-szolgálat végzése során minden illetékes állomás, többek közt:*

a) felelősséggel tartozik a légijárművekkel folytatott kommunikáció céljára megfelelő elsődleges és másodlagos frekvenciák kijelöléséért;

b) vennie kell a helyzet-jelentéseket, és kezelnie kell a légijárművektől származó és a légijárműveknek címzett egyéb, a repülések biztonságos végrehajtása szempontjából elengedhetetlen közleményeket;

c) felelősséggel tartozik a rádióhiba esetére előírt eljárások végrehajtásáért (lásd az 5.2.2.7.2 pontot).

5.2.2.2.5 **PANS.** - *Az elsődleges figyelő-szolgálat átadása egyik állomástól a másiknak általában akkor történik meg, amikor a légijármű átlépi a repülés-tájékoztató körzet vagy a légiforgalmi irányító körzet határát; ezt a figyelő-szolgálatot - amennyire csak lehetséges - bármely időben annak az állomásnak kell nyújtania, amely azt a repülés-tájékoztató központot vagy körzeti irányító központot szolgálja ki, amelynek területén belül a légijármű tartózkodik. Azonban, ha az összeköttetés körülményei ezt szükségessé teszik, egy állomástól megkövetelhetik, hogy az ilyen földrajzi határokon túl is fenntartsa a figyelő-szolgálatot, vagy hogy a figyelő-szolgálatot azelőtt átadja a következő állomásnak, mint ahogy a légijármű elérné a határt, ha ezzel a levegő-föld összeköttetésben észrevehető javulás érhető el.*

5.2.2.3 *A használatos frekvenciák*

5.2.2.3.1 A légijármű-állomások a megfelelő rádiófrekvenciákon kötelesek üzemelni.

5.2.2.3.1.1 A levegő-föld irányító rádióállomás köteles kijelölni az(oka)t a frekvenciá(ka)t, amelye(ke)t, az irányítása alatt álló légijármű-állomásoknak szokványos körülmények között használniuk kell.

5.2.2.3.1.2 **PANS.** - *Hálózatban történő üzemelés esetén az elsődleges és másodlagos frekvenciák első kijelölését a hálózat azon állomásának kell megtennie, amellyel a légijármű a repülés előtti ellenőrzést elvégzi, vagy felszállása után az első összeköttetés felvételét végrehajtja. Ennek az állomásnak kell gondoskodnia arról is, hogy a hálózat többi állomása szükség szerint értesüljön a kijelölt frekvenciá(k)ról.*

5.2.2.3.2 **Ajánlás.** - *Egy légiforgalmi állomás, amikor az 5.2.2.3.1.1 vagy az 5.2.2.3.1.2 pontoknak megfelelő módon kijelöli a frekvenciákat, lehetőleg vegye figyelembe az alkalmazható hullám-terjedési adatokat és azt a távolságot, amelyen keresztül szükség van az összeköttetés fenntartására.*

5.2.2.3.3 **Ajánlás.** - *Ha egy légiforgalmi állomás által kijelölt valamely frekvencia alkalmatlannak bizonyul, a légijármű-állomás lehetőség szerint javasoljon egy másik frekvenciát.*

5.2.2.3.4 **PANS.**- *Amikor a hálózat állomásai az 5.1.1 pont előírásai ellenére a levegő-föld frekvenciákat az állomások közötti koordináció és együttműködés szempontjából szükséges közlemények továbbítására használják, akkor az ilyen közlemény-váltásokat olyan hálózati frekvenciák felhasználásával kell lebonyolítani, amelyeket az adott pillanatban nem használnak fokozott levegő-föld forgalmazásra. A légijármű-állomásokkal folytatott közlemény-váltások minden esetben elsőbbséget kell élvezzenek a földi állomások közötti közlemény-váltásokkal szemben.*

5.2.2.4 *Az összeköttetés felvétele*

5.2.2.4.1 A légijármű-állomások - amennyiben ez lehetséges - közvetlenül azzal a levegő-föld irányító rádióállomással legyenek összeköttetésben, amely megfelel annak az adott körzetnek, ahol a légijárművek éppen repülnek. Ha erre nem képesek, akkor a légijármű-állomásoknak fel kell használniuk bármely rendelkezésére álló, és alkalmas közvetítő eszközt ahhoz, hogy a közleményeiket a levegő-föld irányító rádióállomásnak eljuttassák.

5.2.2.4.2 Ha egy légiforgalmi állomásról egy légijármű-állomással nem lehet rendes összeköttetést létesíteni, akkor a légiforgalmi állomásnak fel kell használnia bármely rendelkezésére álló, alkalmas közvetítő eszközt arra, hogy a légijármű-állomás számára a közleményeit továbbítsa. Ha mindezek a próbálkozások eredménytelenek maradnak, akkor az illetékes Hatóság által előírt eljárások szerint értesíteni kell a közlemény feladóját.

5.2.2.4.3 **PANS.** - *Hálózati üzemelés esetén, ha a légijármű-állomás és egy illetékes állomás között az elsődleges és a másodlagos frekvencián történt hívással nem sikerült összeköttetést teremteni, akkor valamelyik másik, az adott repülés tekintetében illetékes állomásnak kell lehetőség szerint segítséget nyújtania, akár úgy, hogy felhívja az elsőként hívott állomás figyelmét, vagy ha egy hívás egy légijármű- állomástól származik, akkor válaszol a hívásra, és magára vállalja a forgalmazást.*

5.2.2.4.3.1 **PANS.** - *A hálózat többi állomásának hasonló intézkedésekkel lehetőleg csak akkor kell segítséget nyújtaniuk, ha az illetékes állomásokkal az összeköttetés felvételére irányuló kísérletek sikertelenek maradtak.*

5.2.2.4.4 **PANS.** - *Az 5.2.2.4.3 és az 5.2.2.4.3.1 pont előírásait ezenkívül még az alábbi esetekben kell alkalmazni:*
a) az érintett légiforgalmi szolgálati egység kérésére;
b) ha a várt összeköttetés egy légijárművel a várható időn belül nem jön létre, ezért rádióhiba előfordulására gyanakszanak.

Megjegyzés. - Az adott időtartamot az illetékes ATS Hatóság írhatja elő.

5.2.2.5 *HF összeköttetés átadása*

5.2.2.5.1 **PANS.** - *A légijármű-állomást az arra hivatott légiforgalmi állomásnak fel kell kérnie arra, hogy térjen át egyik rádiófrekvenciáról, vagy hálózatról egy másikra. Ilyen közlemény hiányában a légijármű- állomásnak lehetőség szerint értesítenie kell az adott légiforgalmi állomást, mielőtt egy másik frekvenciára áttérne.*

5.2.2.5.2 **PANS.** - *Egyik hálózatról a másikra történő áttérés esetén az átadásnak lehetőleg addig kell megtörténnie, amíg a légijármű egy olyan állomással áll összeköttetésben, amely mindkét hálózatban üzemel, hogy ezzel biztosítsák az összeköttetés folyamatosságát. Ha azonban a hálózatok közti váltást azzal egyidőben kell elvégezni, hogy az összeköttetést egy másik hálózati állomásnak átadják, akkor az átadást a két hálózati állomásnak lehetőség szerint koordinálnia kell, mielőtt a frekvenciaváltást tanácsolnák, vagy arra felhatalmazást adnának. A légijárművel közölni kell az átadás után használandó elsődleges és másodlagos frekvenciákat is.*

5.2.2.5.3 Amikor egy légijármű-állomás az egyik rádiófrekvencia figyeléséről egy másik frekvencia figyelésére tért át, ha az illetékes ATS Hatóság ezt megköveteli, tájékoztassa az érintett légiforgalmi állomást, hogy megkezdte az összeköttetés figyelését az új frekvencián.

5.2.2.5.4 **PANS.** - *Amikor a légijármű felszállása után a légijármű-állomás bejelentkezik egy hálózathoz, akkor meg kell adnia felszállásának idejét, vagy az utolsó ellenőrző pont átrepülésének idejét a megfelelő illetékes állomásnak.*

5.2.2.5.5 **PANS.** - *Amikor a légijármű-állomás új hálózatba lép át, akkor meg kell adnia az utolsó ellenőrző pont feletti átrepülésének idejét, vagy az utolsó jelentett pozíciója idejét a megfelelő illetékes állomásnak.*

5.2.2.5.6 **PANS.** - *Mielőtt a légijármű-állomás elhagyná a hálózatot, lehetőleg minden esetben értesítenie kell a megfelelő illetékes állomást erről a szándékáról - az alábbiak közül - a megfelelő kifejezés továbbításával:*
a) amikor a légijármű-vezető - légiforgalmi irányytó között használt csatornára tér át:
Légijármű: CHANGING TO ... (ÁTKAPCSOLOK A) ... – *(a megfelelő légiforgalmi szolgálati egység neve)*
b) leszállás után:
Légijármű: LANDED ... (LESZÁLLTAM) .... *(hely) ... (idő)*

5.2.2.6 *VHF összeköttetés átadása*

5.2.2.6.1 A légijárművet az illetékes légiforgalmi állomásnak kell felkérnie arra, hogy térjen át egyik frekvenciáról a másikra, az jóváhagyott eljárásoknak megfelelően. Ilyen felkérés hiányában a légijármű-állomásnak kell értesítenie az illetékes légiforgalmi állomást, mielőtt áttér egyik frekvenciáról a másikra.

5.2.2.6.2 Amikor az első kapcsolatot felveszi, illetve a VHF frekvencia elhagyásakor, a légijármű-állomásnak továbbítania kell minden olyan tájékoztatást, amit az illetékes Hatóság előírt számára.

5.2.2.7 *Összeköttetési hiba*

5.2.2.7.1 *Levegő-föld összeköttetés*

5.2.2.7.1.1 Ha egy légijármű-állomásnak nem sikerül összeköttetést létesítenie a légiforgalmi állomással a kijelölt frekvencián, akkor meg kell kísérelnie az összeköttetés felvételét egy az útvonalnak megfelelő másik frekvencián. Amennyiben ez a kísérlet sem sikerül, a légijármű-állomásnak az útvonalnak megfelelő frekvencián meg kell próbálnia összeköttetést létesíteni más légijárművekkel, vagy más légiforgalmi állomásokkal. Ezenkívül, egy hálózatban működő légijárműnek a megfelelő VHF frekvenciát figyelnie kell, hogy képes legyen a közelében lévő légijáművektől érkező hívások vételére.

5.2.2.7.1.2 Ha az 5.2.2.7.1.1 pontban leírt kísérletek eredménytelenek maradnak, a légijármű-állomásnak a "TRANSMITTING BLIND" (vak-adás) kifejezés után közleményét kétszer le kell adnia a kijelölt frekvenciá(ko)n, és ha szükséges, hozzá kell tennie a címzette(ke)t is, aki(k)nek a közleményt szánja.

5.2.2.7.1.2.1 **PANS. -** *Hálózati üzemelés esetén a vak-adással leadandó közleményt kétszer kell leadni az elsődleges és a másodlagos frekvencián is. A frekvencia-váltás előtt a légijármű-állomásnak be kell jelentenie, hogy melyik frekvencia az, amire át fog váltani.*

5.2.2.7.1.3 A v*evőkészülék meghibásodása*

5.2.2.7.1.3.1 Ha egy légijármű-állomás a vevőkészülék hibája miatt nem képes összeköttetést létesíteni, akkor jelentéseit továbbítania kell a használatos frekvencián a megkívánt időpontokban vagy földrajzi helyeken, a "TRANSMITTING BLIND DUE TO RECEIVER FAILURE" ("VAK-ADÁS A VEVŐKÉSZÜLÉK HIBÁJA MIATT") kifejezés után. A légijármű-állomás le kell, hogy adja a szükségesnek ítélt közleményét, majd meg kell ismételnie az egészet. Ezen eljárás során a légijárműnek közölnie kell a következő tervezett adásának időpontját is.

5.2.2.7.1.3.2 Ha a légijármű, légiforgalmi irányítói szolgáltatásban vagy tanácsadói szolgáltatásban részesül, az 5.2.2.7.1.3.1 pont előírásainak betartásán felül adjon tájékoztatást a légijármű parancsnok-pilótájának a repülés folytatásával kapcsolatos szándékáról is.

5.2.2.7.1.3.3 Ha a légijármű a fedélzeti berendezés hibája miatt nem képes összeköttetést létesíteni, akkor ha rendelkezik az ehhez szükséges berendezéssel, állítsa be a megfelelő SSR kódot a rádióhiba jelzésére.

Megjegyzés. - A rádióhiba esetén használható általános szabályokat a Chicagói Egyezmény, ICAO Annex 2 (a Nemzetközi Polgári Repülési Szervezet Egyezményének 2. Függeléke) tartalmazza.

5.2.2.7.2 *Föld-levegő összeköttetés*

5.2.2.7.2.1 Amikor a légiforgalmi állomás nem képes összeköttetést létesíteni egy légijármű-állomással, miután hívta azokon a frekvenciákon, amelyeken a légijármű feltételezhetően figyel, akkor:
a) kérjen fel segítség-nyújtásra más légiforgalmi állomásokat, úgy, hogy a légijárművet meghívják és közvetítik a forgalmazást, ha az szükséges;
b) kérje fel az útvonalon repülő légijárműveket, hogy kíséreljék meg az összeköttetés felvételét az adott légijárművel, és közvetítsék a forgalmazást, ha szükséges.

5.2.2.7.2.2 Az 5.2.2.7.2.1 pont előírásait szintén alkalmazni kell:
a) az érintett légiforgalmi szolgálati egység kérésére;
b) ha a várt összeköttetés egy légijárművel a várható időszakon belül nem jön létre, és ezért rádióhiba előfordulására gyanakszanak.

Megjegyzés. - Az adott időtartamot az illetékes ATS Hatóság írhatja elő.

5.2.2.7.2.3 **Ajánlás. -** *Ha az 5.2.2.7.2.1 pontban leírt kísérletek sikertelenek maradnak, a légiforgalmi állomás a légijárműnek címzett közleményeket - a légiforgalmi irányítói engedélyeket tartalmazó közlemények kivételével - vak-adással kell, hogy leadja azo(ko)n a frekvenciá(ko)n, amelye(ke)n a légijármű feltételezhetően figyel.*

5.2.2.7.2.4 Vak-adással a légijárművek számára nem szabad légiforgalmi irányítói engedélyeket továbbítani, kivéve azt az esetet, ha a közlemény feladója ezt határozottan kéri.

5.2.2.7.3 *A rádióhiba bejelentése.* A levegő-föld irányítói rádióállomás a lehető leghamarabb értesítse a levegő-föld összeköttetés bármely hibájáról az érintett légiforgalmi szolgálati egységeket és a légijárművek járatóit.

5.2.3 A HF közlemények kezelése

5.2.3.1 *Általános előírások*

5.2.3.1.1 **PANS. -** *Hálózati üzemelés esetén a légijármű-állomásnak - ha az össszeköttetés körülményei megengedik - a közleményeit lehetőleg a hálózat azon állomásainak kell leadnia, amelyektől azokat a lehető legkönnyebben, leggyorsabban lehet továbbítani a végső rendeltetési helyeikre. A légijárműveknek különösen a légiforgalmi szolgálatok által megkívánt jelentéseket kell annak a hálózati állomásnak leadniuk, amely azt a repülés-tájékoztató központot, vagy körzeti irányító központot szolgálja ki, amelynek területén belül a légijármű éppen repül. Fordított esetben, a repülésben lévő légijárműveknek szánt közleményeket - amikor csak lehetséges - a légijárművekhez közvetlenül arról a hálózati állomásról kell továbbítani, amelyik a közlemény feladójának helyét szolgálja ki.*

Megjegyzés. - Egy légijárműnek kivételesen szüksége lehet arra, hogy olyan légiforgalmi állomással vegye fel az összeköttetést, amely a repülés adott útvonal-szakaszán belül illetékes hálózaton kívül esik. Amikor a figyelést az illetékes ATS Hatóság előírja, ez megengedhető a légijárművek számára, amennyiben ezt meg lehet tenni anélkül, hogy a légijármű megszakítaná a figyelést azon az összeköttetési hálózaton, amely a repülés adott útvonal-szakaszán illetékes, és feltéve, hogy ezzel nem okoznak zavaró kölcsönhatást más légiforgalmi állomások működésében.

5.2.3.1.2 **PANS. -** *Egy bizonyos légijárműtől valamely hálózati állomásnak szóló közleményeket - amennyiben lehetséges - a hálózat többi olyan állomásának is vennie és nyugtáznia kell, amelyek olyan helyeket szolgálnak ki, ahol az adott információra szintén szükség van.*

1. Megjegyzés. - A címzés nélküli levegő-föld közlemények szétosztására vonatkozó eljárások meghatározása több-oldalú vagy helyi megállapodások útján történik.

2. Megjegyzés. - Elvben az adásokat venni köteles állomások számát, az operatív követelményeknek megfelelően, a lehetséges minimumon kell tartani.

5.2.3.1.2.1 **PANS. -** *Az adás vételét lehetőleg közvetlenül azután kell nyugtázni, miután azon állomás, amelyiknek a közleményt továbbították nyugtázta azt.*

5.2.3.1.2.2 **PANS. -** *A vett adást úgy kell nyugtázni, hogy a közleményt vevő állomás leadja a saját rádió- hívójelét, amelyet a ROGER szó követ - ha szükségesnek ítélik -, valamint annak az állomásnak a hívójelét, amelyik a közleményt leadta.*

5.2.3.1.2.3 **PANS. -** *Ha az adás vételét egy percen belül nem nyugtázzák, akkor annak az állomásnak kell azt továbbítania, amelyik vette a légijárműtől a közleményt, általában a légiforgalmi állandóhelyű* *szolgálaton keresztül, annak/azoknak/ az állomás(ok)nak, amely(ek) nem nyugtázta/nyugtázták/ az adás vételét.*

5.2.3.1.2.3.1 **PANS. -** *Ha rendkívüli körülmények között szükség van rá, hogy az adást a levegő-föld csatornákon keresztül továbbítsák, akkor lehetőség szerint az 5.2.2.3.4 pont előírásait kell betartani.*

5.2.3.1.2.4 **PANS. -** *Ha a továbbítás a légiforgalmi állandóhelyű távközlési hálózaton keresztül történt, akkor a közleményeket az érintett hálózati állomás(ok)nak kell megcímezni.*

5.2.3.1.2.5 **PANS. -** *Az(ok)nak az állomás(ok)nak, amely(ek) részére a közleményeket továbbították, el kell, hogy végezze/végezzék/ a közlemények helyi szétosztását, ugyanolyan módon, mintha a közleményeket közvetlenül a légijárművektől kapta/kapták/ volna a levegő-föld csatornán.*

5.2.3.1.2.6 Az a légiforgalmi állomás, amelyik egy repülésben lévő légijárműről leadott légijelentést (AIREP), vagy meteorológiai tájékoztatást tartalmazó közleményt vesz, köteles késedelem nélkül továbbítani:
1) az állomással kapcsolatban álló légiforgalmi szolgálati egységnek és meteorológiai hivatalnak;
2) az érintett légijármű járatójának, vagy képviselőjének, ha az adott járató kifejezetten kérte, hogy az ilyen közleményeket megkapja.

5.2.3.1.3 **PANS. -** *Az 5.2.3.1.2 pont előírásait, ha ez megvalósítható, a nem-hálózati üzemelés esetén is alkalmazni kell.*

5.2.3.1.4 **Ajánlás. -** *Ha egy légiforgalmi állomás egy repülésben lévő légijárműnek címzett közleményt vesz, olyat, amelynek a közlemény címzésében ez a címzés szintén szerepel, és ha ez az állomás nem képes összeköttetést létesíteni azzal a légijárművel, amelyiknek a közleményt címezték, akkor a közleményt lehetőség szerint továbbítsa az útvonalon található azon légiforgalmi állomások számára, amelyek feltételezhetően összeköttetést tudnak létesíteni a légijárművel.*

Megjegyzés. - Ez nem zárja ki a közleményt továbbító állomás részéről, hogy a címzett légijárműnek leadja az eredeti közleményt, ha a későbbiek során a továbbító állomás mégis összeköttetést tud teremteni az adott légijárművel.

5.2.3.1.4.1 **Ajánlás. -** *Ha a légiforgalmi állomás, amelynek a közleményt címezték, nem tudja továbbítani a közleményt az 5.2.3.1.4 pont előírásai szerint, akkor erről lehetőleg értesítse a közleményt feladó állomást.*

5.2.3.1.4.2 A közleményt továbbító légiforgalmi állomásnak helyesbítenie kell a közlemény címzését oly módon, hogy a saját helység jelölése helyére annak a légiforgalmi állomásnak a helység jelölését írja, amelyiknek a közlemény továbbításra került.

5.2.3.2 *Az ATS (Légiforgalmi Szolgálatok) közlemények továbbítása légijárművek számára*

5.2.3.2.1 **PANS. -** *Ha a légijárműnek egy ATS közleményt nem lehet kézbesíteni az ATS által meghatározott időn belül, akkor a légiforgalmi állomásnak értesítenie kell a közlemény feladóját. Ezután nem kell további intézkedést tennie ezzel a közleménnyel kapcsolatban, hacsak az ATS erre kifejezetten utasítást nem ad.*

5.2.3.2.2 **PANS. -** *Ha egy ATS közlemény kézbesítése bizonytalan, mert nem lehetséges egy közlemény vételének nyugtázását biztosítani, akkor a légiforgalmi állomásnak azt kell feltételeznie, hogy a légijármű nem vette a közleményt, és a közlemény feladóját azonnal értesítenie kell arról, hogy bár a közleményt továbbította, de azt nem nyugtázták.*

5.2.3.2.3 **PANS. -** *Az a légiforgalmi állomás, amely átvette a közleményt az ATS-től, nem ruházhatja át a közleménynek légijármű számára történő kézbesítése felelősséget egy másik állomásra. Jóllehet, összeköttetési nehézségek esetén, ha erre felkérik őket, más állomásoknak is segítséget kell nyújtaniuk a közleménynek a légijármű részére történő közvetítésében. Ebben az esetben annak az állomásnak, amelyik a közleményt az ATS-től átvette, lehetőleg késedelem nélkül egyértelmű megerősítést kell beszereznie arról, hogy a légjármű hibátlanul nyugtázta a közleményt.*

5.2.3.3 *A levegő-föld közlemény-váltások rögzítése távgépírón*

5.2.3.3.1 **PANS. -** *Távgépírón történő rögzítés során az alábbi eljárást kell alkalmazni:*
a) minden sort a bal margónál kell kezdeni;
b) minden adás egy új sorban kell, hogy kezdődjön;
c) minden közlemény-váltásnak az alábbi elemek egy részét, vagy az összes elemet tartalmaznia kell, a következő sorrendben:

1) a hívó állomás hívójele;
2) a közlemény szövege;
3) a hívott állomás, vagy a vevő állomás hívójele, amelyet a megfelelő rövidítés követ, az alábbiak jelzésére: "Vett adás"; "Visszaolvasás ", vagy "Nem volt hallható válasz";
4) az adás vételét nyugtázó állomás(ok) hívójele, amelyet a megfelelő rövidítés követ annak jelzésére, hogy "Vett adás";
5) a használt frekvencia megjelölése;
6) a közlemény-váltás ideje UTC-ben;
d) a közlemény szövegének hiányzó részeit három ponttal (szóköz **.** *szóköz* **.** *szóköz* **.** *szóköz),* vagy *három M betűvel (szóköz M szóköz M szóköz M szóköz) kell jelezni;*
e) a gépelési hibák javítását a billentyűzet segítségével leadott (szóköz E szóköz E szóköz E szóköz) karakter-sorozattal kell bevezetni, ami után a helyes szöveget kell legépelni. A bejegyzés elvégzése után észlelt hibákat az utolsó bejegyzés után kell javítani, a COR rövidítés használatával, amelyet a helyes adat kövessen.

5.2.4 A SELCAL eljárások

Megjegyzés. - Az 5.2.4 pontban leírt eljárások akkor alkalmazhatók, ha SELCAL-t használnak, és ilyenkor ezek helyettesítik az 5.2.1 pontban leírt, a hívással kapcsolatos bizonyos eljárásokat.

5.2.4.1 Általános rész

5.2.4.1.1 **PANS. -** *A SELCAL néven ismert szelektív hívó rendszer alkalmazása során az élőszóval történő hívást a légjármű felé kódolt impulzus-sorozat továbbításával helyettesítik a rádió-távbeszélő csatornáin keresztül. Egy szelektív hívás négy előre kiválasztott hang-impulzusból áll, amelyek továbbításához körülbelül két másodpercre van szükség. A hang-impulzusokat a légiforgalmi állomás kódoló berendezése állítja elő, és a fedélzeten található vevő készülék hangfrekvenciás (audio) kimenetéhez kapcsolt dekódoló berendezés veszi. A kijelölt impulzus-kód (SELCAL-kód) vétele bekapcsolja a pilótafülke hívórendszerét, fény- és/vagy hangjelzés formájában.*

Megjegyzés.- A SELCAL-kódok korlátozott száma miatt ugyanaz a kód több légjármű részére is kijelölésre kerülhet. Ezért az ebben a fejezetben található pontos RTF (rádió-távbeszélő) eljárások használata kiemelten fontos, amikor SELCAL használatával hozzák létre az összeköttetést.

5.2.4.1.2 **PANS. -** *A SELCAL-t a megfelelően felszerelt állomásoknak kell használniuk szelektív hívásra az útvonal-repülési föld-levegő HF és VHF rádió csatornákon.*

5.2.4.1.3 **PANS. -** A *SELCAL-lal felszerelt légjárműveken a légijárművezető továbbra is képes hagyományos figyelést folytatni a frekvencia hallgatásával, ha erre szükség van.*

5.2.4.2 *A légijármű SELCAL kódjának bejelentése a légiforgalmi állomások számára*

5.2.4.2.1 **PANS. -** *A légijármű-üzemeltető ügynökségének (járatójának) és a légijárműnek felelőssége arról gondoskodni, hogy minden légiforgalmi állomás, amellyel a légijármű rendes körülmények között összeköttetést létesít egy adott repülés során, ismerje a légijármű rádió-távbeszélő hívójeléhez rendelt SELCAL-kódot.*

5.2.4.2.2 **PANS. -** *Amikor ez megvalósítható, a légijármű-üzemeltető ügynökség (járató) rendszeres időközönként küldje szét minden érintett légiforgalmi állomásnak a légijárműveihez, vagy járataihoz rendelt SELCAL-kódok listáját.*

5.2.4.2.3 **PANS. -** *A légijárműnek az alábbiakat kell végrehajtania:*
a) a SELCAL-kódját bele kell írnia az illetékes légiforgalmi szolgálati egységnek benyújtott repülési tervbe; és
b) gondoskodnia kell róla, hogy a HF légiforgalmi állomás rendelkezzen a helyes SELCAL-kóddal úgy, hogy átmenetileg összeköttetést létesít a HF légiforgalmi állomással, mialatt a légijármű még az VHF fedés- területen belül található.

Megjegyzés. - A repülési terv kitöltésére vonatkozó előírásokat a "Légiforgalmi Szolgálatok Eljárásai - Légiforgalmi Irányítás Szervezés" /PANS-ATM/ (Doc 4444) kiadvány tartalmazza.

5.2.4.3 *Repülés előtti ellenőrzés*

5.2.4.3.1 **PANS. -** *A légijármű-állomás lépjen összeköttetésbe az illetékes légiforgalmi állomással és kérjen repülés előtti SELCAL ellenőrzést, és ha szükséges, adja meg a SELCAL-kódját.*

5.2.4.3.2 **PANS. -** *Amikor elsődleges és másodlagos frekvenciákat jelöltek ki, a SELCAL ellenőrzést rendes körülmények között először a másodlagos, azután az elsődleges frekvencián kell elvégezni. A légjármű- állomás ezután készen áll a folyamatos közlemény-váltásra az elsődleges frekvencián.*

5.2.4.3.3 **PANS. -** *Ha a repülés előtti ellenőrzés során kiderül, hogy akár a földi, akár a fedélzeti SELCAL berendezés működésképtelen, akkor a légijárműnek lehetőség szerint folyamatosan figyelnie kell további repülése során, egészen addig, amíg a SELCAL ismét használhatóvá válik.*

5.2.4.4 *Az összeköttetés felvétele*

5.2.4.4.1 **PANS. -** *Ha egy légiforgalmi állomás SELCAL használatával kezdeményez hívást, a légijármű a rádió-hívójelével és a "GO AHEAD" ("JÖHET A KÖZLEMÉNYE") kifejezéssel kell, hogy válaszoljon.*

5.2.4.5 *Útvonal-repülés során alkalmazandó eljárások*

5.2.4.5.1 **PANS.** - *A légijármű-állomásnak gondoskodnia kell róla, hogy az illetékes légiforgalmi állomások értesüljenek arról, hogy SELCAL figyelést hozott létre vagy tart fenn.*

5.2.4.5.2 **PANS.** - *Ha a körzeti léginavigációs egyezmények ezt így írják elő, a légjárműtől az előre tervezett jelentések továbbításának kérését a légiforgalmi állomás SELCAL használatával is kezdeményezheti.*

5.2.4.5.3 **PANS. -** *Mihelyt egy bizonyos légijármű-állomás SELCAL figyelést hozott létre, a légiforgalmi állomások lehetőleg a SELCAL-t használják akkor, amikor a légijárművet hívniuk kell.*

5.2.4.5.4 **PANS. -** *Abban az esetben, ha a SELCAL jelre nem érkezik válasz az elsődleges frekvencián végrehajtott két hívás és a másodlagos frekvencián végrehajtott további két hívás után sem, akkor a légiforgalmi állomásnak vissza kell térnie az élőszóban történő híváshoz.*

5.2.4.5.5 **PANS. -** *Hálózatban üzemelő állomásoknak azonnal tájékoztatniuk kell egymást, ha egy földi, vagy egy fedélzeti SELCAL berendezés működésében zavar áll be. Hasonlóképpen, a légijármű (vezetője) is gondoskodjon arról, hogy a repülésével kapcsolatban álló légiforgalmi állomás azonnal tudomást szerezzen a fedélzeti SELCAL berendezésének bármilyen meghibásodásáról, és arról, hogy a továbbiakban élőszóban kell hívnia a légijárművet.*

5.2.4.5.6 **PANS. -** *Minden állomást értesíteni kell akkor, amikor a SELCAL berendezés újra működőképessé válik.*

5.2.4.6 *SELCAL-kódok kiosztása a légijárművek részére*

5.2.4.6.1 **PANS. -** *Elméletben, a SELCAL-kód a légijárművön a rádió-távbeszélő hívójelhez kell, hogy kötődjön, vagyis ha a rádió-hívójelben járatszámot (szolgálati számot) használnak, a SELCAL-kódot a légijárművön a járatszám mellett kell bejegyezni. Minden egyéb esetben a SELCAL-kódot a légijárművön a légijármű lajstromjele mellett kell bejegyezni.*

Megjegyzés. - A járatók világszerte egyre gyakrabban használják a légitársaság nevének rövidítését és a járat szolgálati számát rádiót-ávbeszélő hívójelnek. A légijárművön található SELCAL berendezésnek ezért olyannak kell lennie, amely lehetővé teszi, hogy egy adott kódot a légijármű járatszámához rendeljenek, vagyis olyan berendezésre van szükség, amely képes a kód-kombinációk átállítására. A jelenlegi állapot szerint azonban sok légijárművön a SELCAL berendezés egy-kódos típusú, és az ilyen légijárművek nem tudják teljesíteni a fenti alapelvet. Ez nem zárhatja ki a járatszám típusú hívójelek használatát egy ilyen felszereléssel rendelkező légijárművön, ha ezt a fajta hívójelet kívánják használni, de alapvetően fontos, hogy ha egy-kódos típusú fedélzeti berendezést használnak járatszám típusú rádió-hívójellel együtt, akkor a földi állomásokat tájékoztatni kell minden egyes repülés esetén, hogy milyen SELCAL-kód áll rendelkezésre a légijárművön.

5.3 Vészhelyzeti és sürgősségi rádiótávbeszélő eljárások

5.3.1 Általános rész

Megjegyzés. - Az 5.3 pontban leírt vészhelyzeti és sürgősségi eljárások a rádió-távbeszélő használatára vonatkoznak. Az ITU Rádió Szabályzat S30 cikkelye és az S13 Függelék előírásai általánosan alkalmazhatóak, kivéve, hogy az S30.9 lehetővé teszi más eljárások alkalmazását is ott, ahol kormányzati szinten különleges egyezményeket kötöttek, valamint alkalmazhatóak a légijármű állomások és a tengerészeti mozgó szolgálat állomásai közötti rádiótávbeszélő összeköttetések esetére is.

5.3.1.1 Minden vészhelyzettel, vagy sürgősségi állapottal, körülménnyel kapcsolatos közlemény vészhelyzeti és sürgősségi forgalmazásnak minősül. A vészhelyzeti és a sürgősségi körülmények az alábbiak szerint kerültek meghatározásra:
a) *Kényszerhelyzet /Distress/:* az az állapot, amelyben súlyos és/vagy közvetlen közeli veszély áll fenn, és késedelem nélküli segítségnyújtásra van szükség.
b) *Sürgősség /Urgency/:* az az állapot, amely egy légijármű vagy egyéb jármű, illetve a légijármű fedélzetén vagy a látótávolságon belül lévő személy biztonságát érinti, de amely nem igényli az azonnali segítségnyújtást.

5.3.1.2 A "MAYDAY" rádió-távbeszélő vészhelyzeti kódot és a "PAN PAN" rádió-távbeszélő sürgősségi kódot kell használni vészhelyzetre, illetve sürgősségi állapotra vonatkozó rádió-forgalmazás bevezetéseként, a körülményekhez igazodva.

5.3.1.2.1 A vészhelyzeti és sürgősségi forgalmazás során - bármely későbbi összeköttetés elején, - megengedett a vészhelyzeti és sürgősségi rádió-távbeszélő kódszavak használata.

5.3.1.3 A vészhelyzetben vagy sürgősségi körülmények között lévő légijárművek számára címzett közlemények feladója - az ilyen közlemények számában, terjedelmében és tartalmában - szorítkozzon a körülmények által megkövetelt minimális mértékre.

5.3.1.4 Ha a légijármű által hívott állomás a vészhelyzeti vagy sürgősségi közlemény vételét nem nyugtázza, más állomások kötelesek segítséget nyújtani, ahogy az a helyzetnek megfelelően az 5.3.2.2 és 5.3.3.2 pontban előírásra került.

Megjegyzés.- A "más állomások" fogalma minden olyan állomásra vonatkozik, amely vette a vészhelyzeti vagy sürgősségi közleményt, és bizonyos abban, hogy azt a címzett állomás nem nyugtázta.

5.3.1.5 A vészhelyzeti és sürgősségi forgalmazást általában azon a frekvencián kell fenntartani, amelyen ez a közlemény-váltás elkezdődött, addig, amíg úgy nem ítélik, hogy kielégítőbb segítséget lehet nyújtani, ha az érintett légijárművel az összeköttetést egy másik frekvencián folytatják.

Megjegyzés. - Szükség szerint a 121,5 MHz, vagy egyéb rendelkezésre álló VHF, vagy *HF frekvencia használható.*

5.3.1.6 Általánosságban, a vészhelyzeti és sürgősségi forgalmazás során, a rádió-távbeszélő adásokat lassan és érthetően kell továbbítani, a rögzítés elősegítésére minden szót tisztán kiejtve.

5.3.2 Vészhelyzeti rádió-távbeszélő közlemények

5.3.2.1 *A vészhelyzetben lévő légijármű tevékenysége*

5.3.2.1.1 Azonkívül, hogy egy vészhelyzetben lévő légijárműnek az általa leadott vészhelyzeti közleményt a MAYDAY rádió-távbeszélő vészhelyzeti kóddal kell, hogy bevezessen (*lásd* az 5.3.1.2 pontot), melyet háromszor meg kell ismételnie:
a) a vészhelyzeti közleményt az adott időben használatos levegő-föld frekvencián kell leadni;
b) a vészhelyzeti közlemény az alábbi elemek közül minél többet tartalmazzon, érthetően elmondva, és ha lehet, az alábbi sorrendben:
1) a címzett/hívott állomás neve (ha az idő és a körülmények megengedik);
2) a légijármű azonosítója;
3) a vészhelyzeti állapot természete;
4) a légijármű parancsnokának szándéka;
5) a légijármű pillanatnyi helyzete, repülési magassága (pl. repülési szint /flight level/, tengerszint feletti magasság /altitude/, stb., amelyik alkalmazható), és útirány-szöge /heading/.

1. Megjegyzés. - A fentieket ki lehet egészíteni az alábbi intézkedésekkel:
a) A vészhelyzetben lévő légijármű a vészhelyzeti közleményét leadja a 121,5 MHz kényszerhelyzeti frekvencián, vagy más légiforgalmi mozgó szolgálati frekvencián, ha ezt szükségesnek vagy kívánatosnak tartja. A kényszerhelyzeti frekvencián nem minden légiforgalmi állomás tart folyamatos figyelőszolgálatot;
b) A légijármű a vészhelyzeti közleményét általános adással adja le, ha az idő és a körülmények ezt előnyössé teszik;
c) A légijármű a tengerészeti mozgó szolgálat rádió-távbeszélő hívási frekvenciáin ad;
d) A légijármű felhasznál minden rendelkezésére álló eszközt, hogy felhívja magára a figyelmet és állapotát mások tudomására hozza (beleértve a megfelelő SSR üzemmód és kód aktivizálását is);
e) Bármelyik állomás bármilyen rendelkezésére álló eszközt felhasznál, hogy egy vészhelyzetben lévő légijárműnek segítséget nyújtson;

f) A fenti 5.3.2.1.1 b) pontban felsorolt elemek bármilyen variációját használja, amikor nem maga az adó állomás van vészhelyzetben, feltéve, hogy ezt a körülményt a vészhelyzeti közleményben világosan közli.

2. Megjegyzés. - A címzett állomás általában az az állomás lesz, amellyel a légijármű összeköttetésben van, vagy amelynek illetékességi területén belül a légijárművet éppen üzemeltetik.

5.3.2.2 *A címzett állomás, vagy a vészhelyzeti közleményt elsőként nyugtázó állomás eljárásai*

5.3.2.2.1 A vészhelyzetben lévő légijármű által meghívott állomás, vagy a vészhelyzeti közleményt elsőként nyugtázó állomás köteles:
a) azonnal nyugtázni a vészhelyzeti közleményt;
b) átvenni az összeköttetés irányítását, vagy meghatározott módon és érthetően átruházni ennek felelősségét; ha ez megtörtént, erről értesítse a légijárművet;
c) azonnali intézkedésekkel gondoskodni arról, hogy minden szükséges információt elérhetővé tegyenek:
1) az érintett ATS egység részére;
2) az érintett járató vagy annak képviselője részére, az előre meghatározott eljárások szerint;
Megjegyzés. - Az érintett járató értesítésének követelménye nem rendelkezik elsőbbséggel bármely más intézkedés előtt, amely a vészhelyzetben lévő repülés, vagy a körzetben tartózkodó bármely egyéb repülés biztonságával van összefüggésben, vagy amely kihatással lehet a többi, a körzetbe később várható repülés előrehaladására.
d) szükség szerint figyelmeztetni a többi állomást, hogy ne küldjenek át más légijárművet arra a csatornára, amelyiken a vészhelyzettel kapcsolatos forgalmazás folyik.

5.3.2.3 *Adástilalom elrendelése*

5.3.2.3.1 A vészhelyzetben lévő állomásnak, vagy a vészhelyzeti forgalmazást irányító állomásnak jogában áll az adástilalom elrendelése, akár a mozgó szolgálat minden állomásának az adott körzeten belül, akár bármely állomásra vonatkozóan, amely zavarja a vészhelyzeti forgalmazást. A körülményektől függően ezeket az utasításokat vagy "minden állomásnak", vagy csak egy adott állomásnak kell megcímezni. Mindkét esetben az alábbi szavakat kell használni:

- a "STOP TRANSMITTING" ("Tartson adásszünetet / Fejezze be az adást") kifejezést;
- a MAYDAY rádió-távbeszélő vészhelyzeti kódot.

5.3.2.3.2 Az 5.3.2.3.1 pontban leírt kódok használata a vészhelyzetben lévő légijármű-állomás és a vészhelyzeti forgalmazást irányító állomás számára korlátozottak.

5.3.2.4 *A többi állomás eljárásai*
5.3.2.4.1 A vészhelyzeti közleményeknek korlátlan elsőbbségük van minden egyéb közleményváltással szemben. Egy állomás, amely tudatában van ezeknek a vészhelyzeti körülményeknek, nem adhat az érintett frekvencián, kivéve ha:
a) a vészhelyzet megszűnt, vagy a vészhelyzeti forgalmazás befejeződött;
b) az összes vészhelyzeti forgalmazást más frekvenciára küldtek át;
c) a forgalmazást irányító állomás az adásra engedélyt ad;
d) saját maga az, aki segítséget kell, hogy nyújtson.

5.3.2.4.2 Bármely állomás, amely tud a vészhelyzeti forgalmazásról, és maga nem tud segítséget nyújtani a vészhelyzetben lévő állomásnak, ettől függetlenül köteles figyelni az ilyen közlemény-váltást, amíg nyilvánvalóvá nem válik, hogy az érintett állomás megkapja a segítséget.

5.3.2.5 *A vészhelyzeti forgalmazás és az adásszünet befejezése*

5.3.2.5.1 Ha egy légijármű a továbbiakban már nincs vészhelyzetben, köteles a vészhelyzeti állapotot törlő közleményt leadni.

5.3.2.5.2 Ha a vészhelyzeti forgalmazást irányító állomás bizonyossá válik, hogy a vészhelyzeti közlemény-váltás befejeződött, akkor azonnali intézkedéseket kell tegyen annak biztosítására, hogy ezt a tájékoztatást minél hamarabb a tudomására hozzák:
1) az érintett ATS egységnek;
2) az érintett járatónak, vagy képviselőjének, az előre meghatározott intézkedések szerint.

5.3.2.5.3 A vészhelyzeti forgalmazást és az adásszünetet egy olyan közlemény kiadásával kell befejezni, amely tartalmazza a "DISTRESS TRAFFIC ENDED" kifejezést, azon a frekvencián vagy frekvenciákon, amelyet a vészhelyzeti forgalmazás során használtak. Ezt a közleményt csak a vészhelyzeti forgalmazást irányító állomás adhatja le akkor, miután vette az 5.3.2.5.1 pontban leírt közleményt, ha az illetékes Hatóság erre a tevékenységre felhatalmazta.

5.3.3 Sürgősségi rádió-távbeszélő közlemények

5.3.3.1 *A sürgősségi helyzetet jelentő légijármű tevékenysége, az 5.3.3.4 pontban leírtak kivételével*

5.3.3.1.1 Azonkívül, hogy a sürgősségi közleményt a PAN PAN rádió-távbeszélő sürgősségi kóddal kell kezdeni (*lásd* az 5.3.1.2 pontot), azt lehetőleg háromszor megismételve, valamint a kódcsoport minden egyes tagját a francia "panne" szóval megegyező módon kiejtve, a sürgősségi állapotot jelentő légijárműnek még az alábbi eljárásokat kell betartania:
a) a sürgősségi közleményét az adott időben használatos levegő-föld frekvencián kell leadnia;
b) a sürgősségi közleménynek az alábbi elemek közül mindazokat tartalmaznia kell, melyekre szükség van, érthetően elmondva, és lehetőségek szerint az alábbi sorrendben:
1) a címzett állomás neve;
2) a légijármű azonosítója;
3) a sürgősségi állapot természete;
4) a légijármű parancsnokának szándéka;
5) a légijármű pillanatnyi helyzete, repülési magassága (azaz repülési szint /flight level/, tengerszint feletti magasság /altitude/, stb., amelyik alkalmazható), és útirány-szöge /heading/;
6) minden egyéb hasznos információ.

1. Megjegyzés. - A fenti 5.3.3.1.1 pont előírásai nem zárják ki azt, hogy egy légijármű általános adással adja le a sürgősségi közleményét, ha az idő és a körülmények ezt előnyösebbé teszik.

2. Megjegyzés. - A címzett állomás általában az az állomás lesz, amelyik a légijárművel összeköttetésben volt, vagy amelynek illetékességi körzetében a légijármű pillanatnyilag üzemel.

5.3.3.2 *A címzett állomás, vagy a sürgősségi közleményt elsőként nyugtázó állomás eljárásai*

5.3.3.2.1 Egy sürgősségi helyzetet bejelentő légijármű által meghívott állomás, vagy a sürgősségi közleményt elsőként nyugtázó állomás köteles:
a) nyugtázni a sürgősségi közleményt;
b) azonnali intézkedéseket foganatosítani annak biztosítására, hogy amilyen gyorsan csak lehet, minden szükséges tájékoztatás hozzáférhetővé váljon:
1) az érintett ATS egységek részére;
2) az érintett járatók vagy képviselőik számára, az előre meghatározott eljárások, intézkedések szerint;
Megjegyzés. - Az érintett járató értesítésének követelménye nem rendelkezik elsőbbséggel bármely más intézkedés előtt, amely a sürgősségi helyzetben lévő repülés, vagy a körzetben tartózkodó bármely

egyéb repülés biztonságával van összefüggésben, vagy amely kihatással lehet a többi, a körzetbe később várható repülés előrehaladására.
c) ha szükséges, vegye át a forgalmazás irányítását.

5.3.3.3 Az összes többi állomás eljárása

5.3.3.3.1 A sürgősségi közleményeknek elsőbbségük van minden egyéb közleménnyel szemben, kivéve a vészhelyzeti közleményeket, ést az összes állomásnak vigyáznia kell, hogy ne zavarja a sürgősségi állapottal kapcsolatos forgalmazást.

5.3.3.4 *Az egészségügyi szállítást végző légijármű eljárásai*

5.3.3.4.1 Az 5.3.3.4.2 pontban leírt jel használata azt kell, hogy jelezze, hogy az azt követő közlemény egy védett egészségügyi repülésre vonatkozik, amely megfelel az 1949-es Genfi Egyezményeknek és Kiegészítő Jegyző- könyveinek.

5.3.3.4.2 Az egészségügyi szállítást végző légijármű bejelentésére és azonosítására a lehetőleg háromszor ismételt PAN PAN rádió-távbeszélő sürgősségi jel használatos, amelyben a szavakat a francia "panne" szó kiejtésével megegyezően mondják ki, és ezt az egészségügyi szállító repülések számára kijelölt MAY-DEE-CAL szó kell, hogy kövesse, a francia "médical" szó kiejtésével megegyezően kimondva. A fenti jelölések használata azt jelzi, hogy az ezt követő közlemény védett egészségügyi szállító repülésre vonatkozik. A közleménynek az alábbi adatokat kell tartalmaznia:
a) az egészségügyi szállító légijármű hívójele, vagy az azonosítás egyéb módja;
b) az egészségügyi szállító légijármű helyzete;
c) az egészségügyi szállító repülést végző légijárművek száma és típusa;
d) a tervezett útvonal;
e) az útvonalra, valamint a felszállásra és érkezésre tervezett idő, értelemszerűen; és
f) bármely egyéb információ, mint amilyen a repülési magasság, a figyelt rádió-frekvenciák, a használt nyelvek, valamint a rendelkezésre álló SSR üzemmódok és kódok.

5.3.3.5 *A címzett állomás, vagy az egészségügyi szállítást végző légijármű közleményét vevő további állomások eljárásai*

5.3.3.5.1 Az 5.3.3.2 és az 5.3.3.3 pont előírásait, értelemszerűen, az egészségügyi szállító légijármű közleményeit vevő állomásokra is alkalmazni kell.

5.4 Jogellenes beavatkozással kapcsolatos közlemények

Egy jogtalan beavatkozás alatt álló légijármű által meghívott állomásnak, vagy a légijármű hívását elsőként nyugtázó állomásnak minden lehetséges segítséget meg kell adni a légijármű részére, beleértve az illetékes ATS egység, valamint bármely más állomás, szervezet vagy személy értesítését, amely helyzeténél fogva képes az érintett légijármű repülését segíteni.

6. FEJEZET LÉGIFORGALMI RÁDIÓNAVIGÁCIÓS SZOLGÁLAT

6.1 Általános előírások

6.1.1 A légiforgalmi rádiónavigációs szolgálatba bele kell, hogy tartozzon a nemzetközi légiforgalmi szolgálatoknál használatos rádiónavigációs eszközök összes típusa és rendszere.

6.1.2 Egy rádiónavigációs eszközt, berendezést, amely nincs folyamatos üzemben, ha lehetséges, üzembe kell állítani, ha azt egy légijármű, vagy bármely, a felügyeletét ellátó földi hatóság, vagy egy légijármű járató felhatalmazott képviselője kéri.

6.1.2.1 **Ajánlás. -** *A légijármű az ilyen kéréseket lehetőség szerint az érintett légiforgalmi állomásnak adja le, a rendes körülmények között használt levegő-föld frekvencián.*

6.1.3 Intézkedni kell arra vonatkozóan, hogy a helyi légiforgalmi tájékoztató szolgálati egység késedelem nélkül megkaphassa az alapvetően fontos információkat a nem-látásos /non-visual/ segédeszközök működési állapotáról, a repülés előtti eligazításhoz szükséges formában, az Annex 15 előírásainak megfelelően.

6.2 Iránymérés

Bevezető Megjegyzések

1) *Az iránymérő állomások akár önállóan működnek, akár két, vagy több állomást tartalmazó csoportokban, egy fő iránymérő állomás irányítása alatt.*

2) *Az önállóan működő iránymérő állomás csak saját magához képest mérve tudja megállapítani a légijármű helyzetének irányát.*

6.2.1 **Ajánlás. -** *Az önállóan működő iránymérő állomás, kérésre, lehetőség szerint a következő adatokat adja meg:*
1) a légijármű földrajzi rádió-irányszöge (True Bearing), a megfelelő kifejezés használatával;
2) a légijármű által követendő földrajzi (tényleges) irányszög (True Heading), ha az iránymérő állomás felé akar repülni, a szél-eltérítés figyelembevétele nélkül, a megfelelő kifejezés használatával;
3) a légijárműnek mágneses rádió-irányszöge (Magnetic Bearing), a megfelelő kifejezés használatával;
4) a légijármű által követendő mágneses irányszög (Magnetic Heading), ha az iránymérő állomás felé akar repülni, a szél-eltérítés figyelembevétele nélkül, a megfelelő kifejezés használatával;

6.2.2 **Ajánlás. -** *Ha az iránymérő állomások hálózatként működnek a légijármű helyzetének megállapítású- hoz, akkor az egyes állomások az általuk mért rádió-irányszögeket azonnal küldjék el az iránymérő hálózatot vezérlő állomásnak, azért, hogy lehetővé tegyék a légijármű helyzetének meghatározását.*

6.2.2.1 **Ajánlás.-** *A hálózatot vezérlő állomás a légijárműveknek, kérésre, lehetőleg az alábbi módszerekkel adja meg azok helyzetét:*
1) helyzet egy adott viszonyítási ponthoz képest, vagy szélességi és hosszúsági fokokban megadva, a megfelelő kifejezés használatával;
2) a légijárműnek az iránymérő állomástól, vagy egyéb meghatározott ponttól mért földrajzi irányszöge (True Bearing), a megfelelő kifejezés használatával, valamint távolsága az iránymérő állomástól vagy vonatkoztatási ponttól, a megfelelő kifejezés használatával;
3) a légijármű által akkor követendő mágneses irányszög, a szél-eltérítés figyelembevétele nélkül, ha az iránymérő állomás, vagy egyéb meghatározott pont irányában akar repülni, a megfelelő kifejezés

használatával, valamint távolsága az iránymérő állomástól vagy az adott ponttól, a megfelelő kifejezés használatával.

6.2.3 A légijármű-állomások általában az illetékes légiforgalmi állomástól, vagy az iránymérő hálózatot vezérlő állomástól kérik az állomástól mért rádió-irányszögek, vagy oda vezető irányszögek, valamint helyzetük megadását.

6.2.4 Az állomástól mért rádió-irányszög, vagy az oda vezető irányszög, vagy a helyzet kéréséhez a légijármű állomásnak a "figyelési frekvencián" meg kell hívnia a légiforgalmi állomást, vagy az iránymérést vezérlő állomást. Ezután a légijármű, a megfelelő kifejezés használatával, meg kell, hogy adja a kért szolgáltatás típusát.

6.2.5 Amikor az iránymérő állomás, vagy állomás-soport készen áll a mérésre, a légijármű-állomás által eredetileg hívott állomás, ahol szükséges, adásra kéri fel a légijárművet az iránymérés elvégzéséhez; ha szükséges, közli, hogy a légijármű-állomásnak erre a célra melyik frekvenciát kell használnia, hogy hányszor kell megismételnie az adását, az adás szükséges időtartamát, vagy bármely, az adással kapcsolatos különleges követelményt.

6.2.5.1 Rádió-távbeszélő üzemben a rádió-irányszöget kérő légijármű-állomás az adását hívójelének megismétlésével kell, hogy befejezze. Ha az adás így is túl rövid volt ahhoz, hogy az iránymérő állomás meg tudja határozni a légijármű rádió-irányszögét, akkor a légijárműnek hosszabb ideig kell adásban lennie úgy, hogy egymásután kétszer, kb. tíz másodpercig ad, vagy másféle olyan jelzést ad, mint amit az iránymérő állomás kérhet tőle.

Megjegyzés. - Vannak olyan típusú VHF/DF iránymérő állomások, amelyeknek modulált jelre (beszédre) van szükségük a rádió-irányszög megállapításához.

6.2.6 Ha az iránymérő állomás mérésének eredményét nem ítéli kielégítőnek, akkor fel kell kérnie a légijármű- állomást adásának megismétlésére.

6.2.7 Amikor útirány-szöget (heading), vagy rádió-irányszöget (bearing) kértek, az iránymérő állomásnak azt a légijármű-állomás részére az alábbi formában kell megadnia:
1) a megfelelő kifejezés;
2) rádió-irányszög (bearing), vagy útirány-szög (heading) a rádió-iránymérő állomáshoz viszonyítva, három számjeggyel megadva;
3) a rádió-irányszög pontossági osztálya;
4) a mérés időpontja, ha szükséges.

6.2.8 Ha a légijármű földrajzi helyzetét kérték, az iránymérést vezérlő állomásnak, miután a térképen az egyidejűleg végzett összes mérés eredményét összegezte, meg kell, hogy határozza a légijármű megfigyelt helyzetét, és a mérés eredményét a légijármű-állomás részére a következő formában kell megadnia:
1) a megfelelő kifejezés;
2) a légijármű földrajzi helyzete;
3) a helyzet meghatározásának pontossági osztálya;
4) az észlelés időpontja.

6.2.9 Amint a légijármű-állomás megkapta a kért rádió-irányszöget, vagy útirány-szöget, vagy a tájékoztatást a földrajzi helyzetéről, vissza kell, hogy ismételje a közleményt, hogy azt az állomás megerősítse, vagy helyesbítse.

6.2.10 Amikor a légijármű helyzetét rádiói-rányszög (bearing), vagy útirány-szög (heading), valamint távolság segítségével adják meg egy ismert ponthoz viszonyítva, amely ha nem a mérést végző, a földrajzi helyzetet közlő állomás, akkor a vonatkozási pont a repülőtér, nagyobb város, vagy földrajzi tereptárgy lehet. A repülőteret előnyben kell részesíteni más pontokkal szemben. Amikor vonatkozási pontnak nagyobb lakott területet, vagy várost adnak meg, akkor a rádió-irányszöget, útirány-szöget és a távolságot anak középpontjától kell mérni.

6.2.11 Amikor a légijármű helyzetét földrajzi szélességben és hosszúságban fejezik ki, akkor azt fokokból és percekből álló számcsoporttal kell megadni, melyet értelemszerűen a földrajzi szélesség esetében az N /Észak/, vagy S /Dél/ betű, a földrajzi hosszúság esetén az E /Kelet/, vagy W /Nyugat/ betű követ. Rádiót-ávbeszélő üzemben a NORTH, SOUTH, EAST és WEST szavakat kell használni.

6.2.12 Az iránymérő állomás értékelése alapján a mérések, rádió-irányszögek és földrajzi helyzetek pontosságát az alábbi táblázat szerint kell osztályozni:
Rádió-irányszögek:
"A" osztály - plusz/mínusz 2 fokon belüli pontosság;
"B" osztály - plusz/mínusz 5 fokon belüli pontosság;
"C" osztály - plusz/mínusz 10 fokon belüli pontosság;
"D" osztály - a "C" osztálynál kevésbé pontos.

Földrajzi helyzetek:
"A" osztály - 9,3 km-en (5 NM) belüli pontosság;
"B" osztály - 37 km-en (20 NM) belüli pontosság;
"C" osztály - 92 km-en (50 NM) belüli pontosság;
"D" osztály - a "C" osztálynál kevésbé pontos.

6.2.13 Az iránymérő állomásoknak jogukban áll megtagadni a rádió-irányszögek, útirány-szögek, vagy földrajzi helyzetek közlését, ha a mérés körülményei nem megfelelőek, vagy ha a rádió-irányszögek nincsenek az állomás kalibrálási határain belül, és meg kell adniuk a szolgáltatás megtagadásának okát is.

7. FEJEZET LÉGIFORGALMI HÍRKÖZLŐ SZOLGÁLAT

7.1 Általános előírások

7.1.1 A rádió-adás anyaga
A rádió-adás anyagának szövegét a feladónak kell elkészítenie, a leadni kívánt formában.

7.1.2 Frekvenciák és adás-idők
7.1.2.1 Az adást a meghatározott frekvenciákon, a megadott időpontokban kell elvégezni.

7.1.2.2 Valamennyi adás tervezett időpontját és frekvenciáját a megfelelő dokumentumokban kell közzétenni. Ha a frekvenciákban vagy az adások időpontjában bármely változás történne, azt a változtatás előtt legalább két héttel NOTAM-ban kell közzétenni.* Ezenkívül, ha lehetséges, bármely ilyen változást valamennyi rendszeres adásban be kell jelenteni a változtatást megelőző 48 órán belül úgy, hogy az erről szóló tájékoztatást egyszer le kell adni minden adás elején és végén.

**Megjegyzés. - Ez nem zárja ki valamely szükséghelyzetben a frekvencia azonnali megváltoztatását, ha ez olyan körülmények miatt elengedhetetlen, amelyek nem teszik lehetővé - legalább két héttel a változtatás előtt - egy erre vonatkozó NOTAM kiadását.*

7.1.2.3 A tervezett adásokat (az egymás utáni, kollektív típusú /"sequential collective type"/ adások kivételével) a tervezett időben kell kezdeni, egy általános hívással. Ha egy adást késleltetni kell, akkor egy rövid tájékoztatást kell sugározni a tervezett időpontban, melyben közölni kell az adást vevő állomásokkal, hogy "maradjanak vétel-készen" ("stand by"), megadva a késés percben meghatározott, várható időtartamát.

7.1.2.3.1 Miután egyértelműen közölték, hogy egy adott időszakra maradjanak vétel-készen, az adást nem szabad a megadott időszak vége előtt elkezdeni.

7.1.2.4 Ha az adásokat idő-elosztásos rendszerben végzik, minden állomás pontosan a számára kiosztott időszak lejártakor be kell, hogy fejezze az adását, függetlenül attól, hogy sikerült-e a teljes anyagot továbbítania.

7.1.2.4.1 Az egymás utáni, kollektív típusú adás esetén minden egyes állomásnak készen kell állnia adásának elkezdésére a kijelölt időpontban. Ha egy állomás, bármely ok miatt, nem kezdené meg adását a kijelölt időpontban, ebben az esetben a sorban közvetlen utána következő állomásnak várnia kell, majd a számára kijelölt időpontban kell elkezdenie az adását.

7.1.3 A szolgáltatás megszakadása
Abban az esetben, ha a szolgáltatás megszakadna a közvetítésért felelős állomáson, akkor a közvetítést, ha lehetséges, egy másik állomásnak kell folytatnia addig, amíg a normál szolgáltatás helyre nem áll. Ha ez nem lenne lehetséges, és az adás olyan jellegű, hogy azt állandóhelyű állomások általi vételre szánják, akkor azoknak az állomásoknak, amelyeknek az adást rögzíteniük kell, folytatniuk kell a figyelést a meghatározott frekvenciákon, amíg a normál szolgáltatás helyre nem áll.

7.2 A rádió-távbeszélő hírközlési eljárások

7.2.1 A rádió-adás technikája

7.2.1.1 A rádió-ávbeszélőn keresztül leadott közlemények legyenek - az érthetőség veszélyeztetése nélkül - a lehető legpontosabban megfogalmazottak, legrövidebbek és legtömörebbek.
7.2.1.2 A rádió-ávbeszélő adások során a beszéd sebessége ne haladja meg a percenkénti 100 szót.

7.2.2 Az általános (körözvény) hívás bevezető része

Rádió-távbeszélő üzemben valamennyi rádió-adás bevezető része az általános (körözvény) hívásból, az állomás nevéből, valamint választhatóan az adás időpontjából (UTC) épüljön fel.

Megjegyzés. - Az alábbi példa ennek az eljárásnak az alkalmazását mutatja be:
(általános hívás) ALL STATIONS (Minden állomásnak ..)
(a THIS IS szavak) (ez a ..)
(az állomás neve) NEW YORK RADIO
(a rádió-adás ideje) TIME ZERO ZERO FOUR FIVE (az időpont 0045)

8. FEJEZET LÉGIFORGALMI MOZGÓ SZOLGÁLAT - ADATKAPCSOLATI ÖSSZEKÖTTETÉSEK

8.1 Általános előírások

1. Megjegyzés. - Jóllehet a 8. Fejezet előírásai elsődlegesen a Légiforgalmi Irányítás – légijárművezető közötti digitális adatkapcsolati összeköttetések alkamazására (CPDLC) vonatkoznak, a 8.1 pont előírásai más jellegű adatkapcsolati alkalmazásokra is érvényesek lehetnek, ahol alkalmazhatóak, beleértve az Adatkapcsolat – Légiforgalmi Tájékoztató Szolgálat felhasználást (pl. D-ATIS, D-VOLMET, stb.) is.

2. Megjegyzés. - Ezen rendelkezések értelmében a légiforgalmi mozgó szolgálatra alkalmazható összeköttetési eljárások, értelemszerűen, a légiforgalmi mozgó-műholdas szolgálatra is alkalmazhatók.

8.1.1 Az adatkapcsolati közlemények összeállítása

8.1.1.1 A közlemények szövegét a szabványos közlemény formátumban kell összeállítani (pl. szabványos CPDLC közlemények), nyílt szöveggel, vagy rövidítések és kódok felhasználásával, ahogy ez a 3.7 pontban leírásra került. A nyílt szöveges változat kerülendő, amennyiben a közlemény szövege nagymértékben rövidíthető megfelelő rövidítések és kódok használatával. Kerülni kell az olyan felesleges szavakat és szókapcsolatokat, mint amilyenek az udvariassági kifejezések.

8.1.1.2 Az alábbi karaktereket lehet felhasználni a közlemények összeállítására:
Betűk: ABCDEFGHIJKLMNOPQRSTUVWXYZ
(csak nagybetűk használatával)
Számok: 1 2 3 4 5 6 7 8 9 0
Egyéb jelek:
- (kötöjel)
? (kérdőjel)
: (kettőspont)
((nyitó zárójel)
) (záró zárójel)
. (pont, pont a mondat végén, vagy tizedes pont)
, (vessző)
' (aposztróf)
= (kettős kötőjel, vagy egyenlőségjel)
/ (törtvonal, vagy ferde zárójel)
+ (összeadásjel)
és a szóköz karakter.

A felsorolt karaktereken kívül más karaktereket nem szabad használni a közleményekben.

8.1.1.3 Római számokat nem lehet használni. Ha a közlemény feladója azt szeretné, hogy a címzettet értesítsék arról, hogy római számokat akartak használni a közleményben, akkor arab számot, vagy számokat kell írni, melyek elé a ROMAN ("római") szót kell beszúrni.

8.1.2 Az adatkapcsolati közlemények kijelzése

8.1.2.1 A földi és fedélzeti berendezéseknek lehetővé kell tenniük a közlemények megfelelő megjelenítését, szükség szerinti nyomtatását, valamint tárolását olyan formában, ami lehetővé teszi a kellő időben és kényelmes módon a közlemények visszakeresését, ha az ilyen tevékenység szükségessé válna.

8.1.2.2 Amikor szöveges kijelzésre van szükség, az angol nyelvű megjelenítés a minimális követelmény.

8.2 CPDLC - A Légiforgalmi Irányítás és a légijárművezető közötti digitális adatkapcsolati összeköttetési eljárások

Megjegyzés. - A CPDLC közlemények ebben a fejezetben hivatkozott készlete a PANS-ATM (Légiforgalmi Szolgálatok Eljárásai - Légiforgalmi Irányítás Szervezés), 5. Függelékében található meg.

8.2.1 Valamennyi összeköttetés során mindig a legtökéletesebb fegyelmet kell tanúsítani, betartani.

8.2.1.1 **Ajánlás. -** *A közlemények összeállításánál lehetőleg figyelembe kell venni az emberi teljesítőképesség azon korlátait, amelyek hatással lehetnek a közlemények hibátlan vételére és megértésére.*

Megjegyzés. - Az emberi teljesítőképességgel foglalkozó tájékoztató anyagok az alábbi kiadványokban találhatóak: Az Emberi Tényezőkkel Kapcsolatos Oktatási Kézikönyv *(Doc 9683) és az* Emberi Tényezővel Kapcsolatos Irányelvek az ATM (Légiforgalmi Irányítás Szervezési) Rendszerekben *(Doc 9758).*

8.2.2 A földi és fedélzeti berendezéseknek biztosítaniuk kell a légiforgalmi irányítók és a légijárművezetők számára azt a képességet, hogy az általuk küldendő bármely üzemeltetéssel kapcsolatos közleményt átnézhessék és jóváhagyhassák.

8.2.3 A földi és fedélzeti rendszereknek biztosítaniuk kell a légiforgalmi irányítók és a légijárművezetők részére azt a képességet, hogy bármely általuk vett, üzemeltetéssel kapcsolatos közleményt átnézhessék, jóváhagyhassák, és ha ez alkalmazható, nyugtázhassák.

8.2.4 A légiforgalmi irányító számára biztosítani kell annak lehetőségét, hogy válaszolhasson a közleményekre, beleértve a kényszerhelyzeti közleményeket is, engedélyeket, utasításokat és tanácsokat adhasson, valamint hogy információkat kérhessen és adhasson.

8.2.5 A légijárművezető számára biztosítani kell annak lehetőségét, hogy válaszolhasson a közleményekre, engedélyeket és információkat kérhessen, tájékoztatásokat jelenthessen, valamint hogy egy kényszerhelyzetet bejelenthessen vagy törölhessen.

8.2.6 A légijárművezető és a légiforgalmi irányító számára biztosítani kell annak lehetőségét, hogy egymással olyan közleményeket válthassanak, melyek nem felelnek meg az előre meghatározott közlemény formátumoknak (azaz szabad szöveges közlemények /free text messages/).

8.2.7 Hacsak az illetékes ATS hatóság másként nem rendelkezik, a CPDLC közlemények szóbeli visszaolvasását nem szabad megkövetelni.

8.2.8 A CPDLC létesítése

8.2.8.1 A légiforgalmi irányítót és a légijárművezetőt tájékoztatni kell akkor, amikor a CPDLC kapcsolat sikeresen létrejött.

8.2.8.2 **PANS. -** *A CPDLC-t elegendő időben kell létrehozni ahhoz, hogy ezzel biztosítsák azt, hogy a légijármű az illetékes ATC egységgel álljon összeköttetésben.*

8.2.8.3 A légiforgalmi irányítót és a légijárművezetőt tájékoztatni kell amikor a CPDLC kapcsolat rendelkezésre áll üzemeltetési felhasználásra, az első kapcsolat-felvételnél, valamint akkor is, ha egy meghibásodás után a CPDLC kapcsolat újra helyreáll.

8.2.8.4 A légijárművezetőnek képesnek kell lennie a légiforgalmi irányító szolgáltatást biztosító légiforgalmi irányító egység azonosítására, bármikor, a szolgáltatás igénybevétele során.

8.2.8.5 Amikor a fedélzeti rendszer úgy érzékeli, hogy rendelkezésre áll a CPDLC kapcsolat üzemeltetési felhasználásra, akkor el kell küldenie a FOLYAMATOS ADAT JOGOSULTSÁG /CURRENT DATA ATHORITY/ CPDLC fedélzetről leadott közlemény elemet.

8.2.8.6 *A fedélzetről kezdeményezett CPDLC*

8.2.8.6.1 **PANS. -** *Amikor a Légiforgalmi Irányítás /ATC/ valamely egysége egy váratlan, CPDLC-re irányuló kérést vesz egy légijárműről, akkor meg kell tudja a légijárműtől a kéréséhez vezető körülményeket, hogy meghatározhassa a további intézkedéseket.*

8.2.8.6.2 **PANS. -** *Amikor az ATC egység visszautasít egy CPDLC-re irányuló kérést, meg kell adja a légijárművezető számára a visszautasítás okát, egy megfelelő CPDLC közlemény felhasználásával.*

8.2.8.7 *Az ATC egység által kezdeményezett CPDLC*

8.2.8.7.1 Egy ATC egység csak akkor létesíthet CPDLC kapcsolatot egy légijárművel, ha az adott légijármű még nem létesített CPDLC összeköttetést, vagy ha erre a légijárművel folyamatos CPDLC összeköttetésben lévő ATC egység feljogosítja.

8.2.8.7.2 Amikor egy CPDLC kapcsolat-felvételre irányuló kérést egy légijármű utasít vissza, akkor a visszautasítás okát vagy a NINCS FOLYAMATOS ADAT JOGOSULTSÁG /NOT CURRENT DATA AUTHORITY/, vagy a "NOT AUTHORIZED NEXT DATA AUTHORITY" NEM ENGEDÉLYEZETT A KÖVETKEZŐ ADAT JOGOSULTSÁG /NOT AUTHORIZED NEXT DATA AUTHORITY/ CPDLC fedélzetről küldött közlemény elem segítségével kell közölje, amelyik értelemszerűen az ideillő. A helyi eljárásoknak kell szabályozniuk azt, hogy vajon a visszautasítás okát megjelenítik-e a légiforgalmi irányító számára. Az ATC egység által kezdeményezett CPDLC kapcsolat-felvétel fedélzeti visszautasításának más, az előbb felsoroltaktól eltérő oka nem megengedett.

8.2.9 Az üzemeltetési CPDLC közlemények cseréje

8.2.9.1 A légiforgalmi irányítók és a légijárművezetők CPDLC közleményeiket az előre meghatározott közlemények (közlemény elemek) készletéből, egy szabad szöveges közleményből, vagy ezen elemek kombinációjából kell, hogy összeállítsák.

8.2.9.1.1 **PANS. -** *Amikor CPDLC összeköttetést használnak, és a célnak megfelelő közleményt a PANS-ATM 5. Függelékében található CPDLC szabványos közlemények készlete tartalmazza, akkor a kapcsolódó szabványos közleményt kell használni.*

8.2.9.1.2 **PANS. -** *A 8.2.12.1 pontban előírtak kivételével, ha egy légiforgalmi irányító, vagy egy légijárművezető CPDLC-n keresztül küld közleményt, akkor lehetőség szerint a válasznak is CPDLC-n keresztül kell érkeznie. Amikor a légiforgalmiirányító vagy a légijárművezető beszéd-üzemű összeköttetésben áll, akkor a választ beszéd-üzemű adásban kell leadni.*

8.2.9.1.3 **PANS. -** *Ha egy üzemeltetési választ igénylő CPDLC közleményt a későbbiekben beszéd-üzemű adásban intéznek el, akkor az alkalmazható CPDLC közlemény-lezáró választ kell elküldeni azért, hogy ily módon biztosítsák a CPDLC közlemény-váltás megfelelő szinkronizálását.*

8.2.9.2 Egy CPDLC közlemény összeállításánál nem szabad ötnél több közlemény elemet felhasználni, és az elemek közül csak kettő tartalmazhat útvonal-engedély változókat.

8.2.9.2.1 **PANS. -** *Ahol ez lehetséges, kerülni kell a hosszú közlemények használatát, vagy az olyan közleményekét, amelyek összetett engedély elemeket, vagy engedélyek és információk kombinációját tartalmazzák.*

*Megjegyzés. - A helyi üzemeltetési eljárások kidolgozásával és a CPDLC hatékony, megfelelő üzemeltetési módszereivel foglalkozó tájékoztató anyag az "*Emberi Tényezővel Kapcsolatos Irányelvek az ATM Rendszerekben" című dokumentumban található (Human Factors Guidelines for Air Traffic Management (ATM) Systems - *Doc 9758*).

8.2.9.3 A CPDLC földi rendszereknek és a fedélzeti rendszereknek alkalmasnak kell lenniük a CPDLC közlemények sürgősségi és riasztási jellemző (tulajdonságainak) alkalmazására úgy, hogy a megjelenítés megváltoztatásával felhívják a felhasználók figyelmét a nagyobb elsőbbségű közleményekre.

Megjegyzés. - Egy közlemény vételekor a közlemény jellemzői a CPDLC használójától bizonyos közlemény-kezelési követelmények betartását követelik meg. Valamennyi CPDLC közlemény három jellemzővel rendelkezik: sürgősségi, riasztási és válasz-adási jellemzővel. Amikor egy közlemény összetett közlemény elemeket tartalmaz, akkor a legmagasabb elsőbbséggel rendelkező közlemény elem adott típusa válik az egész közlemény jellemző típusává.

8.2.9.3.1 A sürgősségi jellemzőnek (urgency attribute) kell leírnia a végfelhasználó számára megjelenített, vett közlemények besorolási követelményeit. A sürgősségi típusok a 8-1 Táblázatban találhatók.

8.2.9.3.2 A riasztási jellemzőnek (alert attribute) kell meghatároznia a közlemény vétele után a szükséges riasztás típusát. A riasztás típusait a 8-2 Táblázat tartalmazza.

8.2.9.3.3 A válaszadási jellemzőnek (response attribute) kell meghatároznia az érvényes válaszokat az adott közlemény elem számára. A válasz típusok a 8-3 Táblázatban találhatók az "uplink" (légijárműnek szóló) közleményekre és a 8-4 Táblázatban a "downlink" (légijárműről származó) közleményekre.

8.2.9.3.3.1 **PANS. -** *Amikor egy több elemből álló közleményre kell válaszolni, és a válasz formája egy közlemény elem, akkor a választ az összes közlemény elemre kell vonatkoztatni.*

Megjegyzés. - Például egy több elemből álló közlemény tartalma a: CLIMB TO FL310 MAINTAIN MACH.84. *Az erre érkező* WILCO *válasz mind a két közlemény elemre vonatkozik, és mindkét utasítás elem teljesítését jelenti.*

8.2.9.3.3.2 **PANS.-** *Ha a légijármű egy egyetlen közlemény elemből álló engedélyt, vagy egy több elemből álló engedély közlemény bármely részét nem képes végrehajtani, akkor a légijármű vezetőjének egy* UNABLE *választ kell küldenie az egész közleményre.*

8.2.9.3.3.3 **PANS. -** *A légiforgalmi irányítónak egy* UNABLE *közleménnyel kell válaszolnia, amely a kérés összes elemére vonatkozik, amennyiben egy egyetlen elemből, vagy egy több elemből álló engedélykérésnek nincs olyan eleme, amely jóváhagyható lenne. A folyamatban, érvényben lévő engedélyeket nem szabad megismételni.*

8.2.9.3.3.4 **PANS. -** *Amikor egy egyetlen elemből, vagy egy több elemből álló engedély-kérésnek az összes elemét jóvá lehet hagyni, akkor a légiforgalmi irányítónak olyan engedélyekkel kell válaszolnia, amelyek a kérés minden egyes elemére válaszolnak. Ennek a válasznak lehetőleg egyetlen, a fedélzetre irányuló ("uplink") közleménynek kell lennie.*

8.2.9.3.3.5 **PANS. -** *Amikor egy légiforgalmi irányító egy több elemből álló engedélykérést csak részben tud jóváhagyni, akkor a kérésre úgy kell válaszolnia, hogy engedélyeket ad ki a jóváhagyható* *részekre, és azokra a részekre, amelyek nem hagyhatók jóvá, a folymatban, érvényben lévő engedély(eke)t kell megismételnie, vagy eltérő engedély(eke)t kell kiadnia.*

Megjegyzés. - Például egy több elemből álló fedélzetről származó ("downlink") közlemény az alábbi bemutatott közlemény elemeket tartalmazza:

MAINTAINING FL310
REQUEST CLEARANCE YQM YYG YYT YQX TRACK
X EINN FPL EDDF
REQUEST CLIMB FL350
WE CAN ACCEPT FL390 AT 1139Z
REQUEST MACH .84

Az alábbiakat tartalmazó közleménnyel válaszolható meg:
CLEARED YQM YYG YYT YQX TRACK X EINN FPL EDDF
CLIMB TO FL350
REPORT REACHING
CROSS 52N 30W AT OR AFTER 1150Z
NO SPEED RESTRICTION

8.2.9.3.3.6 **PANS. -** *Amikor egy CPDLC közlemény több, mint egy közleménye lemet tartalmaz és a közleményre a válasz jellemző Y, ha felhasználják, akkor az egyetlen válasz közleménynek a megfelelő számú válaszokat kell tartalmaznia, ugyanabban a sorrendben.*

Megjegyzés.- Például egy több elemből álló "uplink" (légijárműnek szóló) közlemény tartalma:
CONFIRM SQUAWK
WHEN CAN YOU ACCEPT FL410

Az alábbi közleménnyel válaszolható meg:
SQUAWKING 5525
WE CAN ACCEPT FL410 AT 1636Z

8-1. táblázat: Sürgősségi jellemző típusok (fedélzetre irányuló és a légijárműről származó)

Típusa	Leírás	Elsőbbség
D	Distress *(Vészhelyzet)*	1
U	Urgent (*Sűrgősség)*	2
N	Normal *(Normál)*	3
L	Low *(Alacsony)*	4

8-2. táblázat: Riasztási jellemző típusok (fedélzetre irányuló és légijráműtől származó)

Típusa	Leírás	Elsőbbség
H	High (*Magas)*	1
M	Medium (*Közepes)*	2
L	Low *(Alacsony)*	3
N	Nincs szükség riasztásra	4

8-3. táblázat: Válaszadási jellemzők (fedélzetre irányuló)

Típusa	Válasz szükséges	Érvényes válaszok	Elsőbbség
W/U	Igen	WILCO, UNABLE, STANDBY, NOT CURRENT DATA AUTHORITY, NOT AUTHORIZED NEXT DATA AUTHORITY, LOGICAL ACKNOWLEDGEMENT (csak ha szükséges), ERROR	1
A/N	Igen	AFFIRM, NEGATIVE, STANDBY, NOT CURRENT DATA AUTHORTI'Y, NOT AUTHORIZED NEXT DATA AUTHORITY, LOGICAL ACKNOWLEDGEMENT (csak ha szükséges), ERROR	2
R	Igen	ROGER, UNABLE, STANDBY, NOT CURRENT DATA AUTHORITY, NOT AUTHORIZED NEXT DATA AUTHORITY, LOGICAL ACKNOWLEDGEMENT (csak ha szükséges), ERROR	3
Y	Igen	Bármely fedélzetről származó CPDLC közlemény, LOGICAL ACKNOWLEDGEMENT (csak ha szükséges)	4
N	Nem, kivéve ha logikai nyugtázásra van szükség	LOGICAL ACKNOWLEDGEMENT (csak ha szükséges), NOT CURRENT DATA AUTHORTI'Y, NOT AUTHORIZED NEXT DATA AUTHORITY, ERROR	5

8-4. táblázat Válaszadási jellemzők (légijárműtől származó)

Típusa	Válasz szükséges	Érvényes válaszok	Elsőbbség
Y	Igen	Bármely fedélzetre irányuló CPDLC közlemény, LOGICAL ACKNOWLEDGEMENT (csak ha szükséges)	1
N	Nem, kivéve ha logikai nyugtázásra van szükség	LOGICAL ACKNOWLEDGEMENT (csak ha szükséges), SERVICE UNAVAILABLE, FLIGHT PLAN NOT HELD, ERROR	2

8.2.9.4 Amikor egy földi, vagy fedélzeti rendszer "ERROR" (Hiba) CPDLC közleményt hoz létre, akkor a hiba okát is mellékelni kell a közleményben.

8.2.9.5 Az illetékes ATS hatóságnak ki kell választania azokat a PANS-ATM 5. Függelékében található közleményelemeket, melyek a saját légterében az üzemeltetést támogatják Amennyiben egy ATS hatóság úgy dönt, hogy ezeknek a közleménye lemeknek csak egy részhalmazát választja, és a vett közlemény nem tartozik ezek közé, akkor az ATC egységnek a "SERVICE UNAVAILABLE" közleményelem fedélzetre irányuló továbbításával kell válaszolnia.

Megjegyzés. - A vett közlemény további feldolgozására nincs szükség.

8.2.9.5.1 **Ajánlás. -** *Egy légiforgalmi irányító számára lehetőleg csak az adott irányító szektor tevékenységének megfelelő "uplink" közleményeket kell biztosítani.*

Megjegyzés. - A PANS-ATM 5. Függelékében található CPDLC közlemény készletet úgy fejlesztették ki, hogy az különböző ATM (Légiforgalmi Irányítás Szervezési) körülményeknek is megfeleljen.

8.2.9.5.2 Amennyiben az illetékes hatóság szükségesnek ítéli, további előre összeállított szabad szöveges közleményeket kell a légiforgalmi irányító rendelkezésére bocsátani, azokra az esetekre, amikor a PANS-ATM által rendelkezésre álló szabványos (CPDLC) közlemények készlete nem alkalmazható bizonyos követelmények esetén. Ilyen esetekben az illetékes hatóságnak - az üzemeltetőkkel és más, esetleg érintett ATS hatóságokkal konzultálva - össze kell állítania egy listát az előre elkészített szabad szöveges közleményekből.

8.2.9.5.3 A CPDLC közleményelemek felhasznált részhalmazaival, és amennyiben van ilyen, bármely kiegészítő, előre összeállított, szabad szöveges közleménnyel kapcsolatos információt közzé kell tenni a Légiforgalmi Tájékoztató Kiadványban (AIP).

8.2.9.6 *A CPDLC átadása*

*Megjegyzés. - A CPDLC átadásával kapcsolatos részletes tájékoztató a "*Manual of Air Traffic Services Data Link Applications"-ban *(DOC 9694) dokumentumban található.*

8.2.9.6.1 **PANS. -** *Amikor a CPDLC átadásra került, akkor a beszéd-üzemű rádió-összeköttetés és a CPDLC kapcsolat párhuzamosan kell létrejöjjön.*

8.2.9.6.2 **P ANS.-** *Amikor egy légijárművet egy olyan ATC egységtől küldtek át, ahol rendelkezésre áll a CPDLC, egy olyan ATC egységnek, ahol a CPDLC nem használható, a CPDLC összeköttetés bezárását egyidőben kell elkezdeni a beszéd-üzemű rádió-összeköttetés átadásával.*

8.2.9.6.3 Amikor egy CPDLC átadása következtében az adatkapcsolat felett rendelkező egység megváltozik, és még mindig vannak olyan közlemények, amelyekre még nem érkezett lezáró válasz (azaz még közlemények várhatóak), akkor erről a CPDLC átadást végző légiforgalmi irányítót értesíteni kell.

8.2.9.6.3.1 Amennyiben egy légiforgalmi irányító át kell küldje a légijárművet anélkül, hogy válaszolna bármely, még elintézetlen, a fedélzetről származó ("downlink") közlemény(ek)re, a rendszernek rendelkeznie kell azzal a képességgel, hogy automatikusan megküldje a megfelelő lezáró, válaszközlemény(eke)t. Ilyen esetekben, bármely automatikusan elküldendő lezáró válasz közlemény(ek) tartalmát közzé kell tenni a helyi utasításokban.

8.2.9.6.3.2 Amikor a légiforgalmi irányító úgy dönt, hogy átküldi a légijárművet anélkül, hogy megvárná valamely függőben lévő uplink közleményére(közleményeire) a légijárművezető válaszát, a földi rendszernek képesnek kell lennie arra, hogy minden egyes közlemény tekintetében automatikusan lezárja a párbeszédet, mielőtt az átküldés megtörténne.

8.2.9.6.3.2.1 **PANS.-** *A légiforgalmi irányítónak vissza kell térnie a beszédüzemű rádió-összeköttetésre, hogy bármely bizonytalanságot tisztázzon, amely(ek) a függőben lévő közleménnyel(közleményekkel) lehet(nek) kapcsolatban.*

8.2.9.6.4 Amennyiben a CPDLC átadása nem jelenti az adatkapcsolat felett rendelkező egység megváltoztatását, és még további befejezetlen közlemények vannak folyamatban, ezeket a közleményeket vagy az illetékes légiforgalmi irányító számára kell eljuttatni, vagy le kell zárni azokat, a helyi utasításoknak, és ha szükséges, az együttműködési egyezményeknek megfelelő módon.

8.2.10 A CPDLC közlemények kijelzése

Ajánlás. - *Azok az ATC egységek, melyek a PANS-ATM-ben található CPDLC szabványos közleményeket használják, a kapcsolódó szöveget, mely az adott közleményhez társítható, lehetőleg úgy kell megjelenítsék, ahogy azt a PANS-ATM, 5. Függelékében bemutatásra került.*

8.2.11 Szabad szöveges közlemények

PANS. - *A légiforgalmi irányítók és pilóták számára a 8.2.9.5.2 pontban bemutatott, előre összeállított, szabad szöveges közleményeken kívül, más szabad szöveges közlemény használatát lehetőleg el kell kerülni.*

Megjegyzés. - Jóllehet elismert, hogy a nem szokásos és a kényszerhelyzet okozta körülmények szükségessé tehetik a szabad, szöveges közlemények használatát, különösen ha a beszéd-üzemű rádió-összeköttetésben hiba lép fel, a szabad szöveges közlemények használatának elkerülése a tévedés és félreérthetőség lehetőségének csökkentését szolgálja.

8.2.12 Kényszerhelyzetek, veszélyhelyzetek és a berendezés meghibásodása során követendő eljárások

8.2.12.1 **PANS. -** *Amikor egy CPDLC kényszerhelyzeti közleményt vettek, a légiforgalmi irányítónak a lehető leghatékonyabb módon kell nyugtáznia a közlemény vételét.*

8.2.12.2 **PANS. -** *Amikor CPDLC-n keresztül egy olyan jelentésre válaszolnak, amely jogellenes beavatkozásra utal, a "ROGER 7500" fedélzetre irányuló közleményt kell használni.*

8.2.12.3 **PANS. -** *Amikor CPDLC-n keresztül bármely más kényszerhelyzeti közleményre válaszolnak, a "ROGER" fedélzetre irányuló közleményt kell használni.*

8.2.12.4 Amikor egy CPDLC közleményre logikai nyugtázás szükséges, és/vagy egy üzemeltetői válasz, és ez nem érkezik meg, a légijárművezetőt, vagy a légiforgalmi irányítót erre, értelemszerűen, figyelmeztetni kell.

8.2.12.5 *A CPDLC meghibásodása*

8.2.12.5.1 **Ajánlás. -** *A CPDLC hibáját lehetőleg kellő időben észlelni kell.*

8.2.12.5.2 A légiforgalmi irányítót és a légijárművezetőt azonnal figyelmeztetni kell a CPDLC hibás működésére, amint a hibát észlelték.

8.2.12.5.3 **PANS. -** *Amikor a légiforgalmi irányítót, vagy a légijárművezetőt figyelmeztették arra, hogy a CPDLC meghibásodott, és a CPDLC helyreállítása előtt valamelyiküknek összeköttetésbe kell lépnie, akkor vissza kell térniük a beszéd-üzemű kapcsolat-tartásra, ha ez lehetséges, és az információkat a: "CPDLC FAILURE" - kifejezéssel kell bevezetni.*

8.2.12.5.4 **PANS. -** *Azon légiforgalmi irányítók, akiktől megkívánják, hogy a teljes CPDLC földi rendszer hibájáról információkat közvetítsenek valamennyi olyan állomásnak, amely valószínűleg hallhatja a közleményt, az ilyen általános hívással kiadott közleményt az "ALL STATIONS CPDLC FAILURE" ("MINDEN ÁLLOMÁSNAK, A CPDLC MEGHIBÁSODOTT") kifejezéssel kell bevezetniük, melyet a hívó állomás azonosítója kell, hogy kövessen.*

Megjegyzés. - Az ilyen általános hívásra nem várnak választ, kivéve, ha ezt követően az egyes állomásokat felkérik a vétel nyugtázására.

8.2.12.5.5 **PANS. -** *Amikor a CPDLC meghibásodik, és az összeköttetésekben visszatérnek a beszéd-üzemű rádió-kapcsolatra, az összes lezáratlan CPDLC közleményt úgy kell tekinteni, hogy nem jutott el a címzetthez, és a függőben lévő közleményekkel kapcsolatos teljes közlemény-váltást lehetőleg újra kell kezdeni a beszéd-üzemű rádió-kapcsolat felhasználásával.*

8.2.12.5.6 **PANS. -** *Amikor a CPDLC meghibásodott, de helyreállítják mielőtt beszéd-üzemű összeköttetésre kellene áttérni, az összes függőben lévő befejezetlen közleményt úgy kell tekinteni, hogy nem jutott el a címzetthez, és a befejezetlen közleményeket illető teljes közlemény-váltást újra kell kezdeni a CPDLC-n keresztül.*

8.2.12.6 *A CPDLC szándékos kikapcsolása*
8.2.12.6.1 Amennyiben a kommunikációs hálózat, vagy a CPDLC földi rendszerének időleges üzemszüneteltetése előre tervezett, egy NOTAM-ot kell kiadni, amellyel az összes érintett felet előzetesen értesíteni kell az üzemszünet tervezett időtartamáról, és ha szükséges, a felhasználandó beszéd-üzemű rádió-kapcsolat frekvenciáinak részleteiről.

8.2.12.6.2 Az ATC-vel pillanatnyilag kapcsolatban lévő légijárműveket szóban, vagy a CPDLC-n keresztül értesíteni kell a CPDLC szolgáltatás küszöbön álló kieséséről.

8.2.12.6.3 A légiforgalmi irányítónak és a légijárművezetőnek biztosítani kell a CPDLC szolgáltatás azonnali leállításának lehetőségét.

8.2.13 Amennyiben egy légijárművel a CPDLC tesztelése kihatással lehet a légijármű számára nyújtott légiforgalmi szolgáltatásokra, akkor koordináció szükséges az ilyen ellenőrzést megelőzően.

8.2.14 A soronkövetkező irányító egységtől származó engedély-továbbítási szolgáltatás /DCDS/
8.2.14.1 Az illetékes ATS hatóságnak kell eldöntenie azt, hogy egy ATC egységnél alátámasztják-e az útvonal soronkövetkező légiforgalmi irányító egységétől származó engedély továbbítási szolgáltatást.

8.2.14.2 *A soronkövetkező irányító szolgálati egységtől származó engedély-továbbítási szolgáltatás /DCDS/ létrehozása*

8.2.14.2.1 A DCDS szolgáltatását csak a fedélzeti rendszernek kell kezdeményeznie. A kezdeményezésnek jeleznie kell, hogy ez az összeköttetés csak a DCDS-től származó engedély vételére szolgál.

8.2.14.2.2 Amikor egy ATC egység visszautasítja a DCDS-t, meg kell adja a légijárművezetőnek a visszautasítás okát is, a "SERVICE UNAVAILABLE" a légiforgalmi irányító és a légijárművezetők közötti digitális adat-kapcsolati /CPDLC/ közlemény használatával.

8.2.14.3 *A soronkövetkező irányító szolgálati egységtől származó engedély-továbbítási szolgáltatás /DCDS/ üzemeltetése*

8.2.14.3.1 A légiforgalmi irányítót és a légijárművezetőt értesíteni kell, amikor a DCDS rendelkezésre áll az üzemeltetésre.

8.2.14.3.2 A légiforgalmi irányítót és a légijármű vezetőjét értesíteni kell arról, ha a DCDS meghibásodik.

8.2.14.3.3 Azokat a Légiforgalmi Irányítás - légijárművezetők közötti digitális adat-kapcsolati /CPDLC/ közlemény elemeket, amelyek a soronkövetkező irányító szolgálati egységtől származó engedély-továbbítási szolgáltatás-/DCDS/ban megengedett közlemények, körzeti léginavigációs megállapodásokban /Regional Air Navigation Agreement/ kell meghatározni.

8.2.14.3.4 A soronkövetkező szolgálati egységtől származó engedély-továbbítási szolgáltatáson leadott engedély- kérésnek a légiforgalmi irányító számára egyértelműen azonosítottnak kell lennie, hogy az egy ilyen kérés.

8.2.14.3.5 A soronkövetkező szolgálati egységtől származó engedély-továbbítási szolgáltatásban leadott engedélynek a légijárművezető számára egyértelműen azonosítottnak kell lennie, hogy az egy ilyen engedély.

8.2.14.4 *A soronkövetkező szolgálati egységtől származó engedély-továbbítási szolgáltatás /DCDS/ befejezése*

8.2.14.4.1 A DCDS befejezését csak a légijármű fedélzeti rendszer kezdeményezheti.

8.2.14.4.2 A soronkövetkező szolgálati egységtől származó engedély-továbbítási szolgáltatás-/DCDS/-t egy ATC egységgel akkor kell befejezni, amikor a soronkövetkező szolgálati egységtől származó engedély-továbbítási szolgáltatás válik folyamatos adat-jogosultságú szolgálattá.

MELLÉKLETEK AZ ANNEX 10 - II. KÖTETÉHEZ

A II. kötet "A" Melléklete -

A LÉGIFORGALMI TÁVKÖZLÉS TERVEZÉSÉVEL KAPCSOLATOS SPECIÁLIS TÁVKÖZLÉSI KIFEJEZÉSEK ÉS MEGHATÁROZÁSAIK LISTÁJA

1964. március 25-én a Tanács, az ötvenegyedik ülésszaka 11. értekezletén, az ICAO-n belüli általános felhasználásra jóváhagyta az alábbi speciális távközlési kifejezéseket és azok meghatározásait. A Tanács a továbbiakban felkérte az Államokat, hogy ezeket a szakkifejezéseket a jóváhagyott jelentésükben használják, különösen az ICAO-val folytatott levelezésük, kapcsolat-tartásuk során, az ICAO ülések számára benyújtott vitairataikban, és minden más vonatkozó szöveges dokumentumaikban.

A csillaggal jelölt szakkifejezéseket már az Annex 10 szövegében is felhasználták és meghatározták, míg a további szakkifejezések általános használatban vannak a légiforgalmi távközlés szakembereinek körében, de már néhány ICAO értekezleten nehézségeket okoztak, vagy a különböző összejövetelek által az adott szakkifejezésre egymásnak ellentmondó meghatározások születtek.

1. Általános használatra

***Aeronautical telecommunication agency- Légiforgalmi távközlési ügynökség**.*
A Légiforgalmi Távközlési Szolgálat egy, vagy több állomásának üzemeltetéséért felelős ügynökség.

***Aeronautical telecommunication service - Légiforgalmi távközlési szolgálat**.*
Bármely légiforgalmi célra létesített távközlési szolgálat.

Aeronautical telecommunication station - Légiforgalmi távközlési állomás.
A légiforgalmi távközlési szolgálat egy állomása.

Aircraft operating agency - Légijármű-üzemeltető ügynökség (járató).
Az a személy, szervezet vagy vállalkozás, amely egy légijármű üzemeltetésével foglalkozik, vagy arra ajánlatot tesz.

Double channel simplex - Két-csatornás szimplex.
Egyszerű szimplex összeköttetési módszer, amely minden irányba egy- egy frekvencia-csatornát használ.

Megjegyzés. - Ezt a módszert néha kereszt-hullámsáv módszernek is nevezték.

Duplex - Duplex.
Olyan összeköttetés, amelyen keresztül két állomás között, egyidejűleg, mindkét irányban folyhat közlemény-váltás.

Frequency channel - Frekvencia-csatorna.
A frekvencia-spektrum egy összefüggő, folytonos része, amely egy meghatározott rádió-sugárzás fajta felhasználásával adat-továbbításra, átvitelre alkalmazható.

Megjegyzés. - Az adásfajták osztályozását és az egyes átvitel típusokhoz megfelelő frekvencia-spektrum tartományokról szóló információkat (sávszélességeket) az ITU Rádió Szabályzat S2 cikkelye, valamint az S1 Függelék határozza meg.

International telecommunication service - Nemzetközi távközlési szolgálat.
Távközlési szolgálat különböző Államok hivatalai vagy állomásai között, vagy olyan mozgó állomások között, amelyek nem ugyanabban az Államban vannak, vagy különböző Államok fennhatósága alá tartoznak.

Offset frequency simplex - Eltolt frekvenciás szimplex.
Az egyszerű, szimplex összeköttetési módszernek olyan változata, amely a két állomás közötti minden irányban egy-egy, frekvenciasávban kissé eltérő, azonban az üzemeltetésre kijelölt azonos frekvencia tartományba tartozó csatornát használ.

Simplex - Szimplex.
Egy módszer, melyben két állomás között egyszerre csak egy irányban folyhat távközlés.

Megjegyzés. - A légiforgalmi mozgó szolgálat esetében ez a módszer az alábbi részekre osztható fel:
a) egycsatornás szimplex;
b) kétcsatornás szimplex;
c) eltolt frekvenciás szimplex.

Single channel simplex - Egycsatornás szimplex.
Olyan szimplex összeköttetés, ahol a mindkét irányú összeköttetéshez ugyanazt a frekvenciát használják.

2. A légiforgalmi állandóhelyű szolgálat tervezése során használatos kifejezések

Aeronautical fixed service (AFS) - Légiforgalmi állandóhelyű szolgálat.
Meghatározott állandó helyek között létesített távközlési szolgálat, melynek feladata elsősorban a léginavigáció biztonságának, valamint a légiforgalom rendszeres, hatékony és gazdságos működésének elősegítése.

Aeronautical fixed telecommunication network (AFTN) - Légiforgalmi állandóhelyű távközlési hálózat.
A légiforgalmi állandóhelyű áramkörök világméretű rendszere, amelyet a légiforgalmi állandóhelyű szolgálat részeként közlemények, és/vagy digitális adatok olyan állandóhelyű légiforgalmi állomások közötti cseréje érdekében hoztak létre, amely állomások azonos, vagy összeegyeztethető távközlési jellemzőkkel rendelkeznek.

AFTN communication centre - AFTN kommunikációs (távközlő) központ.
Olyan AFTN állomás, amelynek elsődleges feladata a hozzá kapcsolt további AFTN állomásoktól (vagy állomásoknak) az AFTN forgalmazás átjátszása (közvetítése), vagy ismételt feladása.

AFTN destination station - AFTN célállomás.
Az az AFTN állomás, amelynek a közleményt megküldték a címzettnek történő helyi kézbesítésre.

AFTN entry-exit points - AFTN be- és kilépőpontok.
Központok, amelyeken keresztül egy ICAO Léginavigációs Körzetbe belépő vagy kilépő AFTN közleményeknek keresztül kell haladniuk.

AFTN group - AFTN csoport.
A légiforgalmi állandóhelyű hálózat három vagy több rádióállomása, amelyek ugyanazon a rádiófrekvencián forgalmaznak.

AFTN origin station - AFTN feladó állomás.
Az az AFTN állomás, ahol a közleményeket átadják az AFTN hálózaton keresztül történő továbbításra.

AFTN station - AFTN állomás.
Olyan állomás, amely a légiforgalmi állandóhelyű távközlési hálózat (AFTN) részét képezi és annak megfelelően üzemel, egy Állam fennhatósága vagy ellenőrzése alatt.

Automatic relay installation - Automatikus átjátszó állomás.
Olyan távgépíró berendezés, ahol automatikus készüléket alkalmaznak a közlemények átvitelére a bejövő és a kimenő vonalak között.

Megjegyzés: Ez a megnevezés magába foglalja a teljesen automatikus és a fél-automatikus állomásokat, berendezéseket is.

Channel – Csatorna.
A két pont közötti közvetlen állandóhelyű szolgálati összeköttetésre szolgáló egyszerű eszköz.

Circuit - Vonal.
Összeköttetési rendszer, amely magába foglalja a két pont között létező összes közvetlen AFTN csatornát.

Communication centre - Kommunikációs központ.
Légiforgalmi állandóhelyű állomás, amely a hozzá közvetlenül kapcsolódó más légiforgalmi állandóhelyű állomások közötti távközlési forgalmazás átjátszását vagy iújra-feladását végzi.

Fully automatic relay installation - Teljesen automatikus átjátszó állomás.
Olyan távgépíró berendezés, ahol egy bejövő közlemény közvetítési feladatainak értelmezése és az ebből következően szükséges kapcsolatok létrehozása a közlemény iújra-feladása céljából, valamint minden egyéb sendes átjátszási tevékenység automatikusan történik, ezért kezelői beavatkozásra - a felügyeletet kivéve - nincs szükség.

Incoming circuit responsibility list - Bejövő vonalak felelősségi listája.
Egy kommunikációs központ minden egyes bejövő vonalához egy olyan lista, mely azokat a helység azonosítókat sorolja fel, amelyek számára az adott vonalon érkező közlemények tekintetében átjátszási felelősséget kell vállaljanak.

Location indicator - Helységnév-kód.
Az ICAO által előírt szabályoknak megfelelően kialakított és valamely légiforgalmi állandóhelyű állomás helységére kijelölt négy-betűs kódcsoport.

Relay time - Átjátszási idő.
Egy COM központ átjátszási ideje az az időtartam, amely a közlemény központban történő teljes vételének időpontja és egy kimenő vonalon történt teljes leadásának időpontja között eltelik.

Route (AFTN) - Adásvonal (AFTN).
Egy vonal egy bizonyos csatornája által követett nyomvonal.

Routing (AFTN) - Közlemény-útvonal (AFTN).
Az a kiválasztott útvonal, amelyet a közleményeknek az AFTN hálózaton keresztül követniük kell, az átvétel és a címzettnek történő kézbesítés között.

Routing Directory - Adásvonal- címjegyzék
Egy távközlési központban található lista, amely minden egyes címzetthez hozzárendeli a használandó kimenő-vonalat.

Routing List - Adásvonal-lista.
Egy távközlési központban található lista, amely minden egyes címzetthez hozzárendeli a használandó kimenő-vonalat.

Semi-automatic relay installation - Félautomata átjátszó állomás
Olyan távgépíró állomás, ahol egy bejövő közlemény közvetítési feladatainak értelmezéséhez és az ebből következően szükséges kapcsolatok létrehozásához, a közlemény újra-feladása céljából, kezelő személy beavatkozása szükséges, de ahol az átjátszással kapcsolatos minden egyéb rendes tevékenység automatikusan történik.

"Torn-tape" relay installation - Kézi ("tépett szalagos") átjátszó állomás.
Olyan telex állomás, amelyben a közleményeket telex-szalag formájában veszik és játsszák át, és ahol az átjátszással kapcsolatos minden tevékenységhez a kezelő beavatkozása szükséges.

Transit time - Átfutási idő.
Az az időtartam, amely attól az időponttól telik el, hogy a közleményt az AFTN állomáson, a hálózaton történő továbbítás céljára leadják, addig az időpontig, amikor a közlemény a címzett számára hozzáférhetővé válik.

Tributary station - Alárendelt állomás.
Olyan légiforgalmi állandóhelyű állomás, amely kaphat és küldhet közleményeket és/vagy digitális adatokat, de amely nem végez átjátszást, kivéve azon hasonló állomások kiszolgálása céljából, amelyeket ezen keresztül kapccsoltak egy távközlési központhoz.

3. A légiforgalmi mozgó szolgálat tervezése során használatos kifejezések

Aerodrome control radio station - Repülőtéri légiforgalmi irányítás rádióállomása
A repülőtéri irányító torony és a légijárművek vagy mozgó légiforgalmi állomások közötti rádiól-evelezést biztosító állomás.

Aeronautical mobile service - Légiforgalmi mozgó szolgálat.
Légiforgalmi állomások és légijármű-állomások között, vagy légijármű-állomások közötti mozgó szolgálat, melyben mentőtutajok is részt vehetnek; kijelölt segélykérő és kényszerhelyzeti frekvenciákon működő kényszerhelyzeti hely-jeladó állomások ugyancsak részt vehetnek ebben a szolgálatban.

Aeronautical station - Légiforgalmi állomás.
A légiforgalmi mozgó szolgálat földi állomása. Bizonyos esetekben a légiforgalmi állomás hajó fedélzetén, vagy tengerben épült emelvényen is elhelyezhető.

Aircraft station - Légijármű-állomás.
A légiforgalmi mozgó szolgálat mozgó állomása, amely nem mentőtutaj-állomás, és amely légijármű fedélzetén van elhelyezve.

Air-ground communication - Levegő-föld összeköttetés.
Kétirányú összeköttetés a légijárművek és a föld felszínén található állomások vagy helyek között.

Air-ground control radio station - A légiforgalmi irányítás levegő-föld rádióállomása.
Olyan légiforgalmi távközlési állomás, amelynek elsődleges feladata egy adott területen belül a légijárművek üzemelésével és irányításával kapcsolatos távközlési forgalom lebonyolítása.

Air-to-ground communication – Levegő-föld irányú kommunikáció.
Egyirányú összeköttetés a légijárművekről a föld felszínén található állomások vagy helyek felé.

Alternative means of communication - Alternatív távközlési eszközök.
Az elsődlegesen használt módszer mellett alkalmazott,azonos műszaki jellemzőkkel rendelkező összeköttetés.

General purpose system (GP) - Általános célú rendszer (GP).
Levegő-föld rádió-távbeszélő berendezések, amelyek az 5.1.8 pontban felsorolt valamennyi forgalmazást kezelni tudják.

Megjegyzés.- Ebben a rendszerben az összeköttetés általában közvetett, vagyis egy harmadik személy közvetítésével történik.

Ground-to-air communication - Föld-levegő irányú összeköttetés.
Egyirányú összeköttetés a föld felszínén található állomásoktól, vagy helyektől a légijárművek felé.

Non-network communications - Hálózaton kívüli távközlés.
Rádió-távbeszélő összeköttetés, melyet a légiforgalmi mozgó szolgálat egyik olyan állomása hajt végre, amely nemképezi részét rádió-távbeszélő hálózatnak.

Operational control communications - Repülés-üzemi (Járatói) Felügyeleti Összeköttetések
Olyan összeköttetések, amelyek egy repülés megkezdése, folytatása, átirányítása vagy befejezése fölötti felügyelet gyakorlásához szükségesek, a légijármű biztonsága, valamint a repülés rendszeressége és hatékonysága érdekében.

Megjegyzés. - Az ilyen összeköttetések általában a légijármű és a légijárművet üzembentartó ügynökség közötti közlemény-váltáshoz szükségesek.

"Pilot-controller system" - "Pilóta-irányító rendszer".
Olyan levegő-föld rádiót-ávbeszélő berendezések, amelyeket elsősorban azért hoztak létre, hogy eszközt biztosítsanak a légijárművezetők és a légiforgalmi irányítók közötti közvetlen összeköttetéshez.

Primary means of communication - Elsődleges összeköttetési módszer.
A légijármű és a földi állomások közötti összeköttetés fenntartására elsősorban alkalmazott módszer, ahol altermatív módszer igénybevételére is lehetőség van.

Radiotelephony network - Rádió-távbeszélő hálózat.
Légiforgalmi rádió-távbeszélő állomások egy csoportja, amelyek ugyanazon családba tartozó rádió-frekvenciákon üzemelnek és figyelnek, és amelyek meghatározott módon segítik egymást, hogy biztosítsák a levegő-föld összeköttetés maximális megbízhatóságát, üzembiztosságát és a levegő-föld forgalmazás elosztását.

Regular station - Illetékes állomás.
Egy állomás, amelyet a légi-útvonal levegő - föld rádiót-ávbeszélő hálózatot alkotó állomások közül kiválasztottak arra, hogy rendes körülmények között a légijárművekkel tartsa a kapcsolatot, vagy azok adását vegye.

A II. kötet "B" melléklete -

ÚTMUTATÓ ANYAG HOSSZÚ KÖZLEMÉNYEK TOVÁBBÍTÁSÁHOZ AZ AFTN SEGÍTSÉGÉVEL

1. Bevezetés

Azt az összeköttetési követelményt, hogy több külön közleménybedn kell leadni az AFTN hálózaton azt a szöveget, amelynek hossza meghaladja az 1800 karaktert, részletesen a 4.4.5.7 és 4.4.15.3.11 pontok tartalmazzák. Ha a közleményeket két vagy több részre kell osztani, akkor az alábbi eljárást kell alkalmazni.

2. Eljárás

Minden közlemény résznek ugyanazt a címzést és feladó jelzést kell tartalmaznia, valamint minden rész szöveges részének végén meg kell adni a rész sorszámát, az alábbiak szerint:

(Az első közlemény vége) / / END PART 01 / /
(A második közlemény vége) / / END PART 02 / /
... stb. ...
(Az utolsó közlemény vége) / / END PART XX/XX / /

Megjegyzés. - Az alábbi példa ennek az eljárásnak az alkalmazását mutatja be, egy három részes közlemény esetén. A közlemény sorszámát jelző szöveg beleszámít a szöveg karaktereinek számába.

a) *Első közlemény:*

(Címzés) GG EGLLYMYX
(Feladó) 102030 KWBCYMYX
(Szöveg) szöveg
/ / END PART 0l / /
(Zárórész) NNNN

b) *Második közlemény:*

(Címzés) GG EGLLYMYX
(Feladó) 102030 KWBCYMYX
(Szöveg) a szöveg folytatása
/ / END PART 02 / /
(Zárórész) NNNN

c) *Harmadik, és egyben utolsó közlemény:*

(Címzés) GG EGLLYMYX
(Feladó) 102030 KWBCYMYX
(Szöveg) a szöveg maradéka
/ / END PART 03/03 / /
(Zárórész) NNNN

ELŐSZÓ

Történelmi háttér

A Légiforgalmi Távközlés Szabványait és Ajánlott Gyakorlatait a Tanács először 1949. május 30-án fogadta el a Nemzetközi Polgári Repülésről szóló Egyezmény 37. cikkelyében lévő előírásoknak megfelelően (Chicago, 1944) és az Egyezmény 10. Annex-eként jelölte ki. Ezek 1950. március 1-jén lépett hatályba. A Szabványok és Ajánlott Gyakorlatok a Hírközlési Osztály 1949. januárjában tartott Harmadik Ülésszaka ajánlásain alapulnak.

Egészen a Hetedik Kiadásig és azt is beleértve, az Annex 10 egy kötetben került kiadásra, ami négy Részt foglalt magába, a hozzájuk kapcsolt mellékletekkel együtt: az I. Rész – Berendezések és Rendszerek, a II. Rész – Rádiófrekvenciák, a III. Rész – Eljárások és a IV. Rész – Kódok és rövidítések.

A 42. Módosítással a IV. Részt törölték az Annex-ből; és az ebben a részben található kódokat és rövidítéseket egy új dokumentumba, a Doc 8400-ba tették át.

A 44. Módosítás 1965. évi május 31-i elfogadásának eredményeként az Annex 10 Hetedik Kiadása két kötetbe került felosztásra: az I. Kötetbe (Első kiadás) - ami az I. Résztt, a "Berendezések és Rendszerek"-et és a II. Részt,a "Rádiófrekvenciák"-at foglalja magába, valamint a II. Kötetbe (Első kiadás), ami a "Hírközlési Eljárások"-at tartalmazza.

A 70. Módosítás 1995. évi március 20-i elfogadásának eredményeként az Annex 10 átszerkesztésre került úgy, hogy öt kötetet foglal magába: I. Kötet – Rádiónavigációs Berendezések; II. Kötet – Hírközlési eljárások; III. Kötet – Hírközlési rendszerek; IV. Kötet – Légtér-ellenőrző radar és Összeütközést Elkerülő Rendszerek; és az V. Kötet – A Légiforgalmi Rádiófrekvencia Spektrum Felhasználása. A 70. Módosítással a III. és a IV. Kötet 1995-ben került kiadásra és az V. Kötet kiadását a 71. Módosítással tervezték.

Az "A" táblázat mutatja be az Annex 10 III. Kötetének a 70. sz. Módosítást követő eredetét, a bennük lévő legfontosabb témák összefoglalásával, és azokkal az időpontokkal együtt, amikor a Tanács az Annex-et és a módosításokat elfogadta, amikor azok hatályba léptek, és végül amikor alkalmazhatókká váltak.

A Szerződő Államok tevékenysége

Az eltérések bejelentése. A Szerződő Államok figyelmét felhívják az Egyezmény 38. cikkelye értelméből eredő azon kötelezettségükre, amely szerint a Szerződő Államokat felkérik arra, hogy jelentsenek be a Szervezetnek minden olyan eltérést, mely a nemzeti szabályaik és eljárásaik, valamint az ebben az Annex-ben lévő és ezt követően módosított Nemezetközi Szabványok között fennáll.Kérik a Szerződő Államokat, hogy ezt a bejelentést terjesszék ki az ezen Annex-ben lévő Ajánlott Gyakorlatoktól való eltérésekre is, amennyiben az ilyen eltérés lényeges jelentőséggel bír a léginavigáció szempontjából. Továbbá felkérik a Szerződő Államokat, hogy folyamatosan tájékoztassák a Szervezetet minden olyan eltérésről, amely ezt követően felmerül vagy amennyiben bármely korábban bejelentett eltérés megszűnik. Egy, az eltérések bejelentésére vonatkozó külön felkérés kerül megküldésre a Szerződő Államok részére az egyes módosítások elfogadását követően azonnal.

Felhívják ezenkívül az Államok figyelmét az Annex 15 azon előírásaira, amelyek szerint a nemzeti szabályaik és gyakorlataik, valamint az ICAO Szabványok és Ajánlott Gyakorlatok között felmerülő eltéréseket a Légiforgalmi Tájékoztató Szolgálaton keresztül tegyék közzé, az Egyezmény 38. cikkelyében lefektetett, az Államokra vonatkozó kötelezettségen felül.

A tájékoztatás közzététele. Az Annex 10-ben meghatározott Szabványoknak, Ajánlott Gyakorlatoknak és Eljárásoknak megfelelően biztosított, a légijármű üzemeltetéseket érintő berendezések, szolgálatok és eljárások változásait, azok életbeléptetését és megszűntetését be kell jelenteni, és az Annex 15 előírásainak megfelelően kell érvénybe helyezni.
Az Annex szövegének használata a nemzeti szabályzatokban. A Tanács 1948. április 13-án elfogadott egy határozatot, amelyben felhívtj a Szerződő Államok figyelmét annak kívánatosságára, hogy a saját nemzeti szabályaikban - amennyire az csak lehetséges - használják azoknk az ICAO Szabványoknak a pontos kifejezésmódját, amelyek szabályozás jellegűek, ugyamígy a Szabványoktól való eltérések jelölésére is, beleértve minden olyan kiegészítő nemzeti szabályzaot is, amely a léginavigáció biztonsága vagy szabályossága szempontjából fontos. Ahol csak lehetséges, ennek az Annex-nek a szövege szándékosan olyan módon került leírásra, hogy nagyobb szövegbeli változtatás nélkül be lehessen foglalni a nemzeti törvényalkotásba.

Az Annex alkotó-részeinek jogi helyzete

Egy Annex a következő alkotó-részekből épül fel, azonban nem feltétlenül található meg ezek mindegyike minden egyes Annex-ben; és ezek az alábbi jogi helyzetet foglalják el:

1. – Az Annex-et alkotó anyagok a tulajdonképpeni:

a) *Szabványok és Ajánlott Gyakorlatok,* amelyeket a Tanács fogadott el az Egyezmény előírásainak megfelelően.

Meghatározásuk a következő:

Szabvány: A fizikai jellemzőkre, összetételre, anyagra, teljesítőképességre, személyzetre vagy eljárásra vonatkozó minden olyan meghatározás, amelynek egységes alkalmazását a nemzetközi léginavigáció biztonsága szempontjából szükségesnek tekintenek, és amelynek a Szerződő Államok az Egyezmény értelmében eleget kell, hogy tegyenek; a teljesítés lehetetlensége esetén annak bejelentése a Tanács részére a 38. Cikkely alapján kötelező .

Ajánlott Gyakorlat: Fizikai jellemzőkre, összetételre, anyagra, teljesítőképességre, személyzetre vagy eljárásra vonatkozó minden olyan meghatározás, amelynek egységes alkalmazását kívánatosnak tekintik a nemzetközi léginavigáció biztonsága, szabályszerűsége vagy hatékonysága érdekében, és amelynek teljesítésére a Szerződő Államoknak az Egyezmény értelmében törekedniök kell.

b) *Függelékek,* a kényelmi szempontból külön csoportosított anyagok, de ezek részét képezik a Tanács által elfogadott Szabványoknak és Ajánlott Gyakorlatoknak.

c) *Meghatározások,* a Szabványokban és Ajánlott Gyakorlatokban használt azon szakkifejezések értelmezése, amelyek nem maguktól értetődőek, amennyiben azok nem rendelkeznek elfogadott szótári jelentéssel.. Egy meghatározásnak nincs független jogi helyzete, de minden egyes Szabványnak és Ajánlott Gyakorlatnak, amelyben használják, elengedhetetlen részei, mivel a szakkifejezés jelentésének értelmi változása befolyásolná az előírás értelmét.

d) *Táblázatok* és *ábrák,* azok, amelyek kiegészítik vagy illusztrálják azokat a Szabványokat és Ajánlott Gyakotrlatokat, amelyekre azokban utalnak, ezek a vonatkozó Szabványoknak és Ajánlott Gyakorlatoknak részét képezik, és ugyanazzal a jogi helyzettel rendelkeznek.

2. – A Tanács által a Szabványokhoz és Ajánlott Gyakorlatokhoz kapcsolódóan közzétételre elfogadott anyag:

a) *Előszavak*, a Tanács tevékenységén alapuló történeti és magyarázó anyagokat tartalmazzák, és magukba foglalják az Államoknak az Egyezményből és az Elfogadási Határozatból következő - a Szabványok és Ajánlott Gyakorlatok alkalmazására vonatkozó - kötelezettségeinek magyarázatát is, ami a Chicagói Egyezményen és annak Végrehajtási Határozatán alapszik;

b) *Bevezetések,* azok a magyarázó anyagok, amelyekkel az Annex részei, fejezetei vagy szakaszai kezdődnek, azért, hogy a szöveg alkalmazásának megértését segítsék;

c) A *Megjegyzések* a szövegbe beépítve - ahol szükséges - tárgyi információt vagy hivatkozást adnak a Szabványokkal vagy Ajánlott Gyakorlatokkall kapcsolatos kérdésekben, de nem képezik a Szabványok és Ajánlott Gyakorlatok részét;

d) A *Mellékletek* a Szabványokkal és Ajánlott Gyakorlatokkal kapcsolatos kiegészítő anyagokat tartalmazzák, vagy azok alkalmazásához útmutatóként kerültek beépítésre.

A szabadalmi felelősség elutasítása

Felhívjuk a figyelmet annak lehetőségére, hogy az ebben az Annex-ben lévő Szabványok és Ajánlott Gyakorlatok bizonyos elemei lehet, hogy szabadalom vagy egyéb szellemi tulajdoni jog tárgyát képezik. Az ICAO nem vállal felelősséget vagy kötelezettséget azért, hogy nem azonosította az ilyen jogok valamelyikét vagy mindegyikét. Az ICAO nem foglal állást semmilyen "igényelt" találmány vagy egyéb szellemi tulajdoni jog fennállására, érvényességére, tárgyára vagy alkalmazhatóságára vonatkozóan, és azt "vállalja", hogy nincs felelőssége és kötelezettsége ennek megfelelően és ere vonatkozóan.

A nyelv kiválasztása

Ez az Annex négy nyelven került elfogadásra - angolul, franciául, oroszul és spanyolul. Minden egyes Szerződő Államot felkérnek, hogy ezeknek a különféle nyelvű szövegeknek az egyikét válasszák ki nemzeti felhasználásra,valamint az Egyezményben meghatározott egyéb célokból, akár a közvetlen felhasználás, akár a saját nemzeti nyelvre töténő fordítás útján, és ennek megfelelően értesítsék a Szervezetet.

Szerkesztési gyakorlat

A következő gyakorlat kerül következetesen alkalmazásra abból a célból, hogy az egyes állítások jogi helyzete egyetlen pillantással megállapítható legyen: a *Szabványok* vékony antikva betűtípussal vannak nyomtatva; az Ajánlott Gyakorlatok vékony dőlt betűvel vannak szedve, jogi helyzetüket az **Ajánlás** szó jelzi; a *Megjegyzések* vékony dőlt betűvel vannak szedve, jogi helyzetüket a Megjegyzés jelzi.

A következő szerkesztési gyakorlatot követtük az előírások megfogalmazásánál:: a Szabványok esetében a "kell", az Ajánlott Gyakorlatok esetében pedig a "kellene" műveltető igét használtuk. Az ebben a dokumentumban alkalmazott mértékegységek megegyeznek a Nemzetközi Mértékegység Rendszerrel (SI) úgy, ahogy az a Nemzetközi Polgári Repülési Egyezmény 5.Annex-ében meghatározásra került. Ott, ahol az Annex 5 megengedi a nem-SI mértékegységek alternatív használatát, azok zárójelben feltűntetve követik az alap mértékegységet. Ahol a két rendszer szerinti mértékegységek szerepelnek, nem szabad feltételezni azt, hogy az értékek egyenlők és felcserélhetők. Azt azonban el lehet fogadni, hogy a biztonság azonos szintjét lehet elérni, ha bármelyik mértékegység rendszert önállóan alkalmazzák.

Ennek a dokumentumnak bármely részére történő hivatkozás, amelyet egy számmal és/vagy címmel azonosítottak, magába foglalja annak a résznek az összes al-részét is.

“A” táblázat. A Annex 10, III. Kötet módosításai

Módosítás	*Forrás(ok)*	*Témakör(ök)*	*Elfogadva* *Hatályos* *Alkalmazható*
70	Léginavigációs Bizottság; A Légiforgalmi Mozgó-Szolgálati Összeköttetések Szakcsoport (AMPC) Harmadik Ülése	Az új III. Kötet és a Légiforgalmi Mozgó-Műholdas Szolgálatokra (AMSS) vonatkozó Szabványok és Ajánlott Gyakorlatok bevezetése	1995. márc. 20. 1995. júl. 24. 1995. nov. 9.
71	Léginavigációs Bizottság; Speciális Hírközlési/Üzemeltetési Szekció (SP COM/OPS/95) ülés (1995); a Másodlagos Légtér-ellenőrző Radar Fejlesztési és Összeütközés Elkerülési Rendszerek Szakcsoport (SICASP) Ötödik Ülése; a Légiforgalmi Mozgó-Szolgálati Összeköttetések Szakcsoport (AMCP) harmadik ülése	Kiegészítő előírások a Légiforgalmi Távközlési Hálózat /ATN/ S-Módú al-hálózatára vonatkozóan; kiegészítő anyag a 8,33 kHz-es csatorna elkülönítés bevezetéséhez kapcsolódóan; változások az ultra- rövidhullámú VHF sáv levegő-föld összeköttetések védelmére vonatkozó anyagban;	1996. márc. 12. 1995. júl. 15. 1996. nov. 7.

		kiegészítés a VHF digitális összeköttetés /VDL/ rádió-frekvenciás jellemzőire vonatkozó műszaki előírásaihoz.	
72	Léginavigációs Bizottság; A Légiforgalmi Mozgó- Szolgálati Összeköttetések Szakcsoport (AMPC) Negyedik Ülése	Az ultra-rövidhullámú digitális összeköttetésre (VDL) vonatkozó Szabványok és Ajánlott Gyakorlatok /SARPs/ bevezetése és útmutató anyag; a VDL meghatá-rozása és a levegő-föld adatcsere elavult anyagának törlése.	1997. márc. 12. 1997. júl. 21. 1997. nov. 6.
73	Léginavigációs Bizottság; a LégiforgalmiTávközlési Hálózat Szakcsoport (ATNP) második ülése; a Másodlagos Légtér-ellenőrző Radar Fejlesztési és Összeütközés Elkerülési Rendszerek Szakcsoport (SICASP) Hatodik Ülése	Az ATN-re vonatkozó anyag bevezetése; változtatások az S-Módú alhálózat előírásaiban.	1998. márc. 19. 1998. júl. 20. 1998. nov. 5.
74	A Légiforgalmi Mozgó-Szolgálati Összeköttetések Szakcsoport (AMCP) Ötödik Ülése; Léginavigációs Bizottság	Az alábbiak bevezetése: a) Rövidhullámú adat-kapcsolatok előrásai; b) változások a kényszerhelyzeti helyjeladó adóberendezéseinek előírásaiban.	1999. márc. 18. 1999. júl. 19. 1999. nov. 4.
75.	A Légiforgalmi Mozgó-Szolgálati Összeköttetések Szakcsoport (AMCP) Hatodik Ülése; Léginavigációs Bizottság	Változtatások a Légiforgalmi Mozgó-Műholdas Szolgálat /AMSS/ Szbványok és Ajánlott Gyakorlatok-/SARPs/-ban; egy új antenna típus bevezetése; egy új beszéd-üzemű csatorna típus és kiemelt elő- írások az AMSS rendszerek közötti együttműködő-képességre;	2000. márc. 13. 2000. júl. 17. 2000. nov. 2.

		változtatások a VHF digitális összeköt- tetések /VDL/ Szabványok és Ajánlott Gyakorlatok-/SARPs/-ban azzal a lehetséges interferencia csök- kentéssel kapcsolatban, amelyet a jelenlegi Ultra-rövidhullámú /VHF/ beszéd-üzemű összeköttetési rend- szereknél a VHF digitális össze- köttetési adók okozhatnak; változ- tatások az Ultra-rövidhullámú /VHF/ beszéd-üzemű összeköttetési Szab- ványok és Ajánlott Gyakorlatok- /SARPs/-ban az ugyanazon légijármű fedélzetén lévő VDL adóktól eredő interferencia érzéketlenség növelésére.	
76	A LégiforgalmiTávközlési Hálózat Szakcsoport (ATNP) harmadik ülése; a Légiforgalmi Mozgó-Szolgálati Összeköttetések Szakcsoport (AMCP) Hetedik Ülése; a Titkárság tevékenysége a Légiforgalmi Szolgálatok /ATS/ Beszéd-üzemű Kapcsolás és Jelzés Vizsgáló Csoport (AVSSSG) segítségével	A Légiforgalmi Távközlési Hálózat (ATN) rendszer szervezési, biztonsági és igazgatási szolgálatai; a CDIN-re vonatkozó részletes anyag eltávolítása; integrált beszéd-üzemű és adat-kapcsolati rendszer (VDL Mode 3); az adat-kapcsolatot kielégítő légtér-ellenőrzési alkal- mazások (VDL Mode 4); az összes, a VDL 1-es üzemmódra vonatkozó előírás törlése; a VDL 2-es üzemmódra vonatkozó részletes műszaki előírások eltávolítása; a légiforgalmi élőszavas áramkörök; az ITU Rádió- Szabályzatra való hivatkozások felfrissítése.	2001. márc. 12. 2001. júl. 16. 2001. nov. 1.
77	A Másodlagos Légtér-ellenőrző Radar Fejlesztési és Összeütközés Elkerülési Rendszerek Szakcsoport (SICASP)	Az S-Módú alhálózat (I. Rész), Légijármű címzési rendszer (I. Rész).	2002. febr. 27. 2002. júl. 15. 2002. nov. 28.

78.	Léginavigációs Bizottság	A rádiófrekvenciás csatornákra vonatkozó műszaki előírások változásai; s kényszerhelyzeti helyjeladók (ELTs) lajstromozásának bevezetése; a VDL 3- és 4-es üzemmód beépítése a Légiforgalmi Távközlési Hálózat /ATN/ al-hálózati elsőbbségek táblázatába (3-3. táblázat); szerkesztői módosítások.	2003. márc. 5. 2003. júl. 14. 2003. nov. 27.
79.	Légiforgalmi Mozgó-Szolgálati Összeköttetések Szakcsoport (AMCP) Nyolcadik Ülése	Változások a Rövidhullámú adatkapcsolatokra (HFDL) vonatkozó műszaki előírásokban, azért, hogy összehangolásra kerüljenek a Nemzetközi Távközlési Unió /ITU/ Rádió-Szabályzatának vonatkozó előírásaival; frekvencia-modulációs /FM/ érzéketlenségi jellemzők bevezetése a VDL Mode 4-re; annak a megjegyzésnek a törlése, amely azt közölte, hogy a VDL Mode 4 Szabványait és Ajánlott Gyakorlatait kell alkalmazni a légtér-ellenőrzési berendezésekre.	2004. febr. 23. 2004. júl. 12. 2004. nov. 25.
80.	Léginavigációs Bizottság	A 406 MHz-es frekvencián üzemelő kényszerhelyzeti helyjeladó adóberendezésekben (ELT-k) használt elhelyezési protokolokra vonatkozó előírások.	2005. febr. 25. 2005. júl. 11. 2005. nov. 24.
81.	Nincs változás		

NEMZETKÖZI SZABVÁNYOK ÉS AJÁNLOTT ELJÁRÁSOK

I. RÉSZ – DIGITÁLIS ADAT-ÖSSZEKÖTTETÉSI RENDSZEREK

1. FEJEZET. MEGHATÁROZÁSOK

1. Megjegyzés. – A "Radio Regulations"-ra történő minden hivatkozás a Nemzetközi Távközlési Egyesület (ITU) által közzétett Nemzetközi Rádió-Szabályzatra vonatkozik. A Nemzetközi Rádió-Szabályzat újra és újra módosításra kerül az általában két vagy háromévenként megrendezésre kerülő Rádió-távközlési Világ-konferenciák (World Radiocommunication Conferences) záróközleményeiben kifejezett döntéseknek megfelelően. A Nemzetközi Távközlési Egyesület /ITU/ eljárásainak azon részeit, melyek a légiforgalmi rádiórendszerek frekvenciáinak a felhasználására vonatkozó további információkat tartalmazzák, a Polgári Légiközlekedés Rádiófrekvencia Spektrum Követelmények Kézikönyve (Handbook on Radio Frequency Spectrum Requirements for civil Aviation) *(Doc 9718) foglalja össze, amely egyúttal a jóváhgyott ICAO elvek ismertetését is magába foglalja.*

2. Megjegyzés. – Az Annex 10-nek ez a Része az összeköttetési rendszerek meghatározott berendezéseire vonatkozó Szabványokat és Ajánlott Gyakorlatokat foglalja magába. Jóllehet, a Szerződő Államok fogják meghatározni a vonatkozó Szabványokban vagy Ajánlott Gyakorlatokban leírt feltételekkel összhangban a meghatározott berendezések telepítési szükségességének felülvizsgálatát, és az érintett Szerződő Államokra vonatkozó ICAO véleményt és az ajánlásokat a Tanács hajtja végre rendszeres időközönként, a szokásos módon a Körzeti Léginavigációs Értekezletek ajánlásai alapján (Doc 8144, Körzeti Léginavigációs Értekezletek Irányelvei és azok Végrehajtási Eljárásainak Szabályai).

3. Megjegyzés. – Ez a fejezet az összeköttetési rendszerekre vonatkozó általános meghatározásokat foglalja magába. Az ebben a kötetben lévő egyes rendszerekre vonatkozó speciális meghatározások a megfelelő fejezetekben találhatók.

4. Megjegyzés. – Az összeköttetési rendszerek másodlagos energia-ellátásra és a megbízhatóságukra, valamint a rendelkezésre állásukra vonatkozó anyagot az Annex 10, I. Kötet 2.9 pontja és az "F" Melléklet foglalja magába külön-külön.

Aeronautical telecommunication network(ATN). <u>Légiforgalmi Távközlési Hálózat (ATN).</u> Egy belső hálózati kiépítés, amely lehetővé teszi a földi, levegő-föld és repülési adat al-hálózatok számára az együttműködést egymás között, a Nemzetközi Szabványügyi Szervezet (ISO) Nyilt Rendszer Összekapcsolás (OSI) referencia modelen alapuló közös interfész szolgáltatás és protokolok elfogadásával.

Aircraft address. <u>Légijármű címzés.</u> Huszonnégy bit egyedi kombinációja, amely egy légijármű számára kijelölésére rendelkezésre áll a levegő-föld összeköttetés, a navigáció és légtér-ellenőrzés céljára.

Aircraft earth station (AES). <u>Légijármű fedélzeti földi állomás (AES).</u> Mozgó földi állomás a repülési mozgó műholdas szolgáltatásban, amely egy légijármű fedélzetén van elhelyezve (lásd még ("GES").

Bit error rate (BER). <u>Bit hiba-arány (BER).</u> Egy mintavételben található bit hibák száma, osztva a mintavételben lévő összes bitek számával, általában sok ilyen mintavétellel átlagolva.

Carrier-to-multipath ratio (C/M). <u>Direkt több-utas vivőfrekvenciás teljesítmény viszonyszám.</u> A vivőfrekvencia teljesítmény közvetlenül vett, azaz visszaverődés nélküli viszonyszáma, a több-utas teljesítményhez, azaz a visszavert vivőfrekvencia teljesítményhez képest.

Carrier-to-noise density ratio (C/N_0). Vivőfrekvencia zajsűrűség viszonyszám (C/N_0). A teljes vivőfrekvencia teljesítmény viszonyszáma az 1 Hz sávszélességhez tartozó átlagos zaj-teljesítményhez képest, amelyet rendszerint dBHz-ben fejeznek ki.

Channel rate. Csatorna átviteli sebesség. Az a sebesség, amellyel biteket visznek át az RF csatornán keresztül. Ezek a bitek tartalmazzák azokat a biteket, amelyeket keretezésre és hiba-korrekcióhoz használnak, valamint az információt hordozó biteket. A kötegelt adatátvitel esetében az átviteli sebesség a kötegelés időtartama alatti pillanatnyi kötegelési sebességre vonatkozik.

Channel rate accuracy. Csatorna átviteli sebesség pontossága. Ez annak az órajelnek a relatív pontossága, amelyhez az átvitt csatorna-biteket szinkronizálják. Például, az 1,2 kbit/s csatorna átviteli sebességnél a 10^6 egy részének maximális hibája, amely magában foglalja a maximálisan megengedett órajel-hibát, $\pm 1{,}2 \times 10^{-3}$ Hz.

Circuit mode. Áramköri módozat. Az összeköttetési hálózatok egy konfigurációja, amely megjeleníti egy speciális célú átviteli útvonal alkalmazási területét.

Doppler shift. Doppler-eltolódás. A vevő egységnél megfigyelt frekvencia-eltolódás, amely az adó egység és a vevő egység közötti relatív elmozdulás következménye.

End-to-end. Végponttól-végpontig. Teljes kommunikációs úthoz tartozó, vagy arra vonatkozó, tipikusan (1) az információ-forrás és a kommunikációs rendszer közötti, az átviteli végen lévő interfésztől (2) a kommunikációs rendszer és az információ-használó, vagy -feldolgozó, vagy alkalmazó közötti, a vételi végen lévő interfészig tartó összeköttetési útvonal.

End-user. Végfelhasználó. Az információ végső forrása és/vagy felhasználója.

Energy per symbol to noise density ratio. (E_s/N_0) Jel-zaj teljesítmény viszony (E_s/N_0). A csatorna-szimbólumonként kisugárzott átlagos energia és az átlagos zaj teljesítmény viszonyszáma az 1 Hz sávszélességben, rendszerint dB-en kifejezve. Az A-BPSK és A-QPSK esetében egy csatorna-szimbólum egy csatorna-bitnek felel meg.

Equivalent isotropically radiated power (e.i.r.p.) Izotropikusan kisugárzott egyenértékű teljesítmény (e.i.r.p.) Az antennába táplált teljesítmény és az antennának egy megadott irányban az izotróp antennához viszonyított teljesítmény nyeresége *(abszolút vagy izotróp nyereség).*

Forward error correction (FEC). Adat-továbbítási hiba védelem (FEC). A továbbított jel redundáns információval oly módon történő kiegészítésének folyamata, amely lehetővé teszi a továbbításban jelentkező hibák kijavítását a vevőnél.

Gain-to-noise temperature ratio. Nyereség-zaj hőmérsékleti viszonyszám. Az antenna al-rendszer vevő oldali kimenetén az antenna-nyereség és zaj viszonyszáma rendszerint dB/K-ban kifejezve. A zajt annak a hőmérsékletnek az értékeként fejezik ki, amellyel egy 1 Ohm-os ellenállás hőmérsékletének emelkedni kell az ugyanakkora zaj teljesítmény-sűrűség előállításához.

Ground earth station. Földi telepítésű földi állomás (GES). A műholdas állandóhelyű szolgálat, vagy néhány esetben a műholdas légiforgalmi mozgó-szolgálat földi állomása, amelyet egy meghatározott állandó földi helyre telepítenek a műholdas légiforgalmi mozgó-zolgálat részére távkapcsolat nyújtása céljából.

Megjegyzés. – Ezt a meghatározást az ITU Nemzetközi Rádió-Szabályzata a "repülési földi állomás" meghatározásaként használja. A Szabványok és Ajánlott Gyakorlatok-(SARPs)-ban alkalmazott "GES" meghatározásának az a célja, hogy egyértelműen megkülönböztesse ezt egy légijármű fedélzetén elhelyezett földi állomástól (AES), amely egy légijármű fedélzetén lévő mozgó állomás.

Mode S subnetwork. Mód S al-hálózat. A másodlagos légtér-ellenőrző radar (SSR) Mode S kérdező és válaszadó egységek felhasználásával - meghatározott protokolok szerint végzett digitális adatcsere céljára szolgáló eszköz.

Packet. Adatcsomag. Hálózati szintű összeköttetési eszközök közötti adatcsere alapegysége.

Packet layer protocol (PLP). Adatcsomag réteg protokol (PLP). Egyenrangú egységek közötti hálózati szintű összeköttetés létesítésére és fenntartására, valamint adatcsomagok átvitelére szolgáló protokol. Ezen szabványvonatkozásában a hivatkozott kifejezés arra a protokolra vonatkozik, melyet az ISO 8208 szabványban határoztak meg.

Point-to-point. Ponttól-pontig. Két, főképpen végfelhasználói berendezés, egymással való kölcsönös összeköttetéséhez tartozó, vagy arra vonatkozó, két különálló végfelhasználót összekötő szolgáltatás kommunikációs útvonala, megkülönböztetésként a közvetítő- és a több-pontú szolgáltatástól.

Slotted aloha. Időosztásios távközlési csatorna használat. Véletlenszerű hozzáférhetőség stratégiája, ahol több felhasználó egymástól függetlenül férhet hozzá ugyanahhoz az adatátviteli csatornához, de minden összeköttetést egy rögzített résidőre kell korlátozni. Az összes felhasználó ismeri ugyanazon résidő szerkezetet, de egyéb koordináció nincs a felhasználók között.

Switched virtual circuit (SVC). Kapcsolt virtuális áramkör (SVC). Az ISO 8208 protokolon belül szolgáltatott elsődleges áramkör vezérlő eljárás. A hálózati forrásokat dinamikusan kiosztják, amikor szükség van rájuk, és felszabadítják, ha már nincs igény rájuk.

Time division multiplex (TDM). Időosztásos multiplex (TDM). Egy csatorna-megosztási stratégia, amelyben az azonos forrásból származó, de különböző rendeltetési helyű információ-csomagokat időrendben sorba-rendezik ugyanazon a csatornán.

Time division multiplex access (TDMA). Időosztásos multiplex hozzáférés (TDMA). Egy RF csatorna időmegosztásos használatán alapuló, többszörös hozzáférési séma, amely a következőket alkalmazza: (1) diszkrét szomszédos idő-réseket, mint alapvető megosztott forrást; és (2) működő protokolok egy halmazát, amely lehetővé teszi a használók számára, hogy együttműködjenek egy vezérlő irányító állomással a csatorna elérés elősegítésére.

Transit delay. Átviteli késedelem. Az összeállított adatcsomag továbbítására irányuló kérés és a vevő-oldali megfelelő csomag vételére és felhasználására vagy továbbítására való készségre vonatkozó jelzés között eltelt idő, kötegelt adat rendszerekben.

VHF digital link (VDL). VHF (ultrarövidhullámú) digitális összeköttetés. A repülési távközlési hálózat (ATN) alkotó részét képező mozgó al-hálózat, amely a repülési mozgó VHF frekvencia-sávban üzemel. Ezenkívül, a VDL nem-ATN funkciókat is szolgáltat, mint például digitalizált hangot.

2. FEJEZET. ÁLTALÁNOS RÉSZ

(Kidolgozás alatt)

3. FEJEZET. LÉGIFORGALMI TÁVKÖZLÉSI HÁLÓZAT

3.1 MEGHATÁROZÁSOK

1. Megjegyzés. – A következő meghatározásokat az ISO/IEC 7498-1, Information technology – Open Systems Interconnection – Basic Reference Model (Információs technológia – Nyilt rendszerek belső kapcsolás – Alap referencia model) (*Reference: ITU-T Rec. X. 200 (1194) és az ICAO Doc 9705 –* Manual of Technical Provisions for the Aeronautical Telecommunication Network (ATN) (Légiforgalmi Távközlési Hálózat Műszaki Előírásai Kézikönyv) *meghatározásaiból vettük.*

2. Megjegyzés. – Az ICAO Doc 9705 több kiadást ért meg. Ennek a dokumentumnak mindegyik alkötete jelezte az előírások alakulását az egymást követő kiadások között.

3. Megjegyzés. – Az ICAO Doc 9705 I. alkötete egy kereszt-hivatkozási grafikont szolgáltat a változatok (azaz beépített szoftver képessége) és kiadványok (azaz műszaki előírások) között.

Accounting management. Forgalmi kezelés**.** Egy olyan rendszer kezelési berendezés, amely a felhasználók hálózati erőforrás felhasználásait kezeli, ellenőrzi és korlátozza az erőforrások felhasználását.

ADS application. ADS alkalmazás. Egy olyan Légiforgalmi Távközlési Hálózati /ATN/ alkalmazás, amely a légijárművektől származó automatikus berendezés-függő légtér-ellenőrző /ADS/ adatokkal látja el a Légiforgalmi Szolgálati /ATS/ Egysége(ke)t, légtérellenőrzési célokra.

Aeronautical administrative communication (AAC). Légiforgalmi igazgatási közlemény-váltás. Repülés-üzemeltető ügynökségek által használt, a repülési és szállítási szolgáltatásaikra vonatkozó üzleti közlemény-váltás. Ezt a közlemény-váltási formát széleskörűen alkalmazzák, mint például la repülési és földi szállításokra, könyvelésre, személyzet és légijármű üzembe-állítására, vagy más logisztikai célokra a teljes repülés üzemeltetés hatékonyságának fenntartása vagy növelése érdekében.

Aeronautical operational control (AOC). Repülés-üzemi járatói felügyelet (AOC). A repülések indítás, folytatása, átirányítása vagy befejezése céljából, azok biztonsága, rendszeressége és hatékonysága érdekében végzett felügyelet ellátásához megkövetelt jártói kapcsolat-tartás.

Aeronautical passanger communication) (APC). Légiutasok távközlése (APC). Nem biztonsági jellegű beszéd- és adat-szolgáltatási kapcsolat-tartás utasok és repülő-hajózó személyzeti tagok részére személyes közlemény váltáshoz.

AIDC application. ATS Egységek közötti automatikus adatcsere (AIDC) alkalmazás. Egy olyan Légiforgalmi Távközlési Hálózati /ATN/ alkalmazás, melynek rendeltetése a Légiforgalmi Irányítás (ATC) Légiforgalmi Szolgálati Egységei (ATSUs) közötti információ cserére szzolgál, a repülési értesítések, a repülés koordináció, az összeköttetés átadása, a légtérellenőrzési adatok továbbítása,valamint általános adatok továbbítása céljára.

Air traffic service. Légiforgalmi szolgálat. (ATS) Gyűjtőfogalom, ami jelenthet repülés-tájékoztató szolgálatot, repülőtéri repülés-tájékoztató szolgálatot, riasztó szolgálatot, légiforgalmi tanácsadó szolgálatot, légiforgalmi irányító szolgálatot (körzeti, bevezető, vagy repülőtéri).

Application. Alkalmazás. Egy információs rendszer végső felhasználása; magától a rendszertől való megkülönböztetésként.

Application entity (AE). Alkalmazási entitás (AE). Az alkalmazási folyamat azon része, amely a Nyílt Rendszerek Összekapcsolásának (OSI) környezetén belül az összeköttetéseket érinti. Egy alkalmazási folyamat szempontjait, amelyeket az OSI céljainál figyelembe kell venni, egy vagy több Alkalmazási Entitás (AE) képviseli.

Application information. Alkalmazási információ. Az alkalmazási nevekre utal (például: az AE /Alkalmazási entitás/ minősítők mint az ADS /Automatikus berendezés-függő légtér-ellenőrző rendszer/ és a CPC), a típus száma és a címzése (a hosszú vagy rövid TSAP, ahogyan szükséges), minden egyes alkalmazásnál.

ATIS application. ATIS alkalmazás. Egy olyan FIS /Repülés-tájékoztató Szolgálati Alkalmazás/, ami alátámasztja a D-ATIS- /Digitális Automatikus Közel-körzeti Tájékoztató Szolgálat/-ot.

ATN directory services (DIR). ATN katalógus szolgáltatás (DIR) Egy szolgáltatás, amely biztosítja egy alkalmazási entitás vagy felhasználó részére azt, hogy az ATN közösségben egy elosztott katalógus adatbázisról lekérdezhessen és visszakereshessen címzési, biztonsági és műszaki képességi információkat az ATN közösségen belüli más felhasználókról és entitásokról.

ATN security services. ATN biztonsági szolgáltatás. A biztonság előírások információs készlete, amely lehetővé teszi a vevő 'végső' állomás vagy közbenső rendszer állomás részére a vett információk forrásának egyértelmű azonosítását (hitelesen), és ezen információk sértetlenségének ellenőrzését.

ATN systems management (SM). ATN rendszer kezelés (SM). Berendezések készlete azon források vezérlésére, koordinálására és ellenőrzésére, amely lehetővé teszi azt, hogy az összeköttetések az ATN rendszerben létrejöjjenek. Ezek a berendezések magukba foglalják a hiba kezelését, az elszámolás, a felépítés kezelést, a teljesítmény kezelését és a biztonsági kezelést.

ATSC class. ATSC osztály. Az ATSC osztály paraméter lehetővé teszi az ATSC használója számára a felkínált adatoknál várható szolgáltatási minőség meghatározását. Az ATSC osztály értéke az ATN végtől-végig való átvitel 95 százalékos valószínűségű késése fogalmával van meghatározva.

ATS communications (ATSC). ATS összeköttetés (ATSC). A légiforgalmi szolgáltatásokkal kapcsolatos összeköttetés, a légiforgalmi szolgáltatások a légiforgalmi irányítást, a repülési és meteorológiai információkat, a helyzet-jelentéseket és a repülés biztonságával, valamint rendszerességével kapcsolatos szolgáltatásokat foglalja magában. Ez az összeköttetés egy vagy több légiforgalmi szolgálati adminisztrációt foglal magában. Ezt a fogalmat címzésekkel kapcsolatos adminisztratív célokra használják.

ATS interfacility data communication (AICD). ATS egységek közötti automatikus adatcsere (AIDC). Automatizált adatcsere légiforgalmi szolgálati egységek között, különösen a repülések koordinációja és átadása vonatkozásában..

ATS message handling services (ATSMHS). ATS közlemény továbbítási eljárások (ATSMHS). Az ATS közlemények ATN-en keresztüli cseréjéhez használt eljárások oly módon, hogy egy ATS közlemény továbbítása általában nem korrelál a szolgálatot nyujtó másik ATS közlemény továbbításával. Két ATS közlemény kezelési szolgálat van, az ATS közlemény-küldő szolgálat és az ATN átmenő szolgálat.

ATS unit (ATSU). ATS egység (ATSU). Gyűjtőfogalom, amely jelenthet légiforgalmi irányító egységet, repülés-tájékoztató egységet vagy légiforgalmi szolgálatok bejelentő irodáját.

Authentication. Hitelesítés. Egy személy/felhasználó/hálózati entitás azonosságának bizto- sítására használt folyamat.

Authorized path. Engedélyezett összeköttetési útvonal. Összeköttetési útvonal, amelyet az adott terület ügyvezetése(i) mint adott forgalom típushoz és kategóriához alkalmasat, előre meghatározott (meghatároztak).

Automatic dependent surveillance (ADS). Berendezés-függő automatikus légtér-ellenőrző rendszer (ADS). Légtér-ellenőrzési mód, amikor egy légijármű adatátviteli csatornán keresztül automatikusan továbbítja a fedélzeti navigációs és helyzet-jelentő rendszerektől származó adatokat, beleértve a légijármű hívójelét, a négy-dimenziós helyzet-tájékoztatást és szükség szerint, egyéb adatokat is.

Automatic terminal information service (ATIS). Automatikus közel-körzeti tájékoztató szolgálat (ATIS). Egész nap, vagy a nap meghatározott részében aktuális, rutin jellegű tájékoztatások biztosítása az érkező és az induló légijárművek részére.

Adat-kapcsolat - Automatikus közel-körzeti tájékoztató szolgálat (D-ATIS). Adat-kapcsolat útján történő ATIS biztosítása.

Beszéd-üzemű - Automatikus közel-körzeti tájékoztató szolgálat. (Beszéd-üzemű ATIS). Folyamatos és ismétlődő, általános adások útján történő ATIS biztosítása.

Configuration management. Konfigurációs kezelési eljárás. ATN rendszer kezelési berendezés a kezelők részére a távirányítású elemek konfigurációinak megváltoztatásához.

Context management (CM) application. Bejelentkezési eljárás. Olyan ATN alkalmazás, amely bejelentkezési szolgáltatást nyújtva, kezdeti légijármű beiktatást, továbbá a légijárműre vonatkozó összes többi adat-kapcsolat alkalmazás jegyzéke beiktatását teszi lehetővé az ATN-be. Magában foglalja továbbá az ATS egységek közötti címzés küldő funkciót.

Megjegyzés. – A bejelentkezési eljárás egy elismert OSI bemutató réteg fogalom. Az OSI használatnak és az ATN használatnak egyébként nincs közös területe.

Context management (CM) server. Bejelentkezési eljárás szerver. Egy olyan Légiforgalmi Szolgálati /ATS/ berendezés, amely képes arra, hogy alkalmazási információt biztosítson más ATSU-kra vonatkozóan légijárműtől, vagy ATSU-tól kérve.

Controller-pilot data link communication (CPDLC). Légiforgalmi irányító és légijármű- vezető közötti digitális adatcsere. A légiforgalmi irányító és a légijárművezető közötti távközlési módszer, ahol az ATC közleményeket adatátviteli összeköttetés segítségével továbbítják.

CPDLC application. CPDLC alkalmazás. Olyan Légiforalmi Távközlési Hálózati /ATN/ alkalmazás, amely eszközt biztosít a légiforgalmi irányítói adat-összeköttetésben az irányító, a vevő vagy a soronkövetkező Légiforgalmi Szolgálati /ATS/ egységek és a légijármű között, a levegő-föld és föld-föld alhálózatokat felhasználva, és ami összeegyeztethető az ICAO szakkifejezésekkel ,a Légiforgalmi Irányítás jelenlegi élőszavas összeköttetéseivel.

Data integrity. Adat sértetlenség. Annak a valószínűsége, hogy az adat nem változik meg, illetve nem sérül meg.

D-METAR. D-METAR. A Digitális Adat-kapcsolaton keresztül biztosított repülési időjárás-jelentő szolgálat jelölésére használatos rövidítés.

End system (ES). Vég-rendszer (ES). Rendszer, amely tartalmazza az OSI hét rétegét és egy vagy több végső felhasználó alkalmazási folyamatot foglal magába.

End to end. Végpontttól-végpontig. Teljes kommunikációs úthoz tartozó vagy arra vonatkozó, tipikusan (1) az információ-forrás és a kommunikációs rendszer közötti, az átviteli végen lévő interfésztől (2) a kommunikációs rendszer és az információ használó vagy feldolgozó, illetve alkalmazó közötti, a vételi végen lévő interfészig tartó összeköttetési útvonal.

Entity. Entitás**.** Aktív elem bármely rétegben, amely lehet vagy egy szoftver entitás (mint például egy folyamat) vagy egy hardver entitás (mint például egy intelligens input-output chip).

Fault management. Meghibásodás kezelés. Egy olyan Légiforgalmi Távközlési Hálózati /ATN/ rendszer kezelő berendezés, amely érzékeli, elkülöníti és kijavítja a problémákat.

FIS application. Repülés-tájékoztató Szolgálati /FIS/ alkalmazás. Egy olyan Légiforgalmi Távközlési Hálózat /ATN/ alkalmazás, amely a légijárművek részére tájékoztatásokat és hasznos tanácsokat biztosít a repülések biztonságos és eredményes lefolytatásához.

Flight information service. **(FIS)** Repülés-tájékoztató Szolgálat (FIS). Olyan szolgálat, amelyet a repülések biztonságos és hatékony végrehajtásához hasznos tanácsok és tájékoz- tatások adása céljából nyújtanak.

Inter-centre communications (ICC) Központok közötti digitális közlemény-váltás (ICC). Az ICC az ATS egységek közötti adat-kapcsolati összeköttetést jelent, az ATS támogatása érdekében olyan területeken, mint például repülésekről szóló előzetes tájékoztatás, koordinálás, irányítás-átadás, repüléstervezés, légtér-gazdálkodás és légiforgalmi áramlás- szervezés.

Intermediate system (IS). Közbenső rendszer. Rendszer, amely átviteli és útvonalazási funkciót lát el és az OSI referencia model legalsó három rétegére szorítkozik.

Internet communications service. Hálózatok közötti távközlési szolgáltatás. A hálózatok közötti távközlési szolgáltatás egy hálózatközi architektúra, amely lehetővé teszi földi, levegő-föld és repülés-elektronikai alhálózatok együttműködését közös interfész szolgálatok és protokolok elfogadásával az ISO/OSI referencia model alapján.

METAR application. METAR alkalmazás. Egy olyan Repülés-tájékoztatási Szolgálati /FIS/ alkalmazás, amely alátámasztja a. D-METAR közlemények továbbítását.

Open systems interconnection (OSI) reference model. Nyílt rendszerek (OSI) referencia model. Model, amely szabvány megközelítést szolgáltat a hálózat tervezéshez, modularitást bevezetve a funkciók komplex együttesének hét jobban kezelhető, önálló funkcionális rétegre osztásával. Ezeket egyezményesenn általában függőlegesen rakott halmazként írják le.

Megjegyzés – Az OSI referencia modelt az ISO/IEC 7498-1 határozza meg. .

Performance management. Teljesítmény felügyelet. Egy Légiforgalmi Távközlési Hálózati /ATN/ rendszer felügyelő berendezés, amely ellenőrzi és kiértékeli a rendszer teljesítményét.

Subnetwork. Alhálózat. Az adathálózat tényleges megvalósítása, amely homogén protokolt és címzés-tervet alkalmaz és egyetlen hatóság irányítása alatt áll.

System level requirement. Rendszerszint követelmény. A rendszerszint követelmény egy magasszintű műszaki követelmény, amely üzemelési követelményekből, technológiai korlátozásokból és szabályozási korlátozásokból (adminisztratív és intézményi) van levezetve. A rendszerszint követelmények szolgálnak alapul a funkcionális követelményekhez és az alacsonyabb szintű követelményekhez.

Transit delay. Átviteli késedelem. Köteg adat-rendszerekben egy összeállított adat-köteg továbbítására irányuló kérés és a vevő oldal arra vonatkozó jelzése között eltelt idő, hogy a hozzátartozó köteget vette és felhasználásra vagy továbbításra kész.

Upper layers (UL) communications service. Felső rétegű (UL) kommunikációs szolgáltatás. Az OSI referencia model gyűjtő, bemutató és alkalmazó rétegeihez tartozó fogalom.

3.2 BEVEZETÉS

3.2.1 A Légiforgalmi Távközlési Hálózat (ATN) olyan alkalmazási entitásokat és összeköttetési szolgáltatásokat foglal magába, amelyek lehetővé teszik a földi, levegő-föld és repülési adat alhálózatok részére a Nemzetközi Szabványügyi Szervezet (ISO) Nyílt Rend- szerek (OSI) összeköttetési referencia modeljén alapuló közös interfész szolgáltatásainak és protokoljainak együttműködését. Az ATN koncepcionális modeljét a 3-1.* ábra mutatja be.

* Az összes ábra ennek a fejezetnek a végén található.

3.2.2 A Légiforgalmi Távközlési Hálózat /ATN/ és a hozzá kapcsolódó alkalmazási folyamatok úgy vannak tervezve, hogy alátámasszák az összeköttetést, a navigációt, a légtér-ellenőrzést és légiforgalmi szolgáltatás szervezési (CNS/ATM) rendszereket. A Légiforgalmi Távközlési Hálózat /ATN/:

a) kifejezetten és kizárólagosan arra a célra szolgál, hogy összeköttetési szolgáltatást biztosítson a légiforgalmi szolgáltatásokat biztosító szervezeteknek és a légijármű üzemeltető cégeknek, az összeköttetési forgalom következő típusain keresztül:

1) a Légiforgalmi Szolgálatok összeköttetései (ATSC);

2) a Repülés-üzemi járatói felügyelet (AOC);

3) a Légiforgalmi igazgatási közlemény-váltás (AAC); és

4) a légiutasok távközlése (APC);

b) a felhasználó számára átlátható módon biztosítja azt a megbízható végpontból-végpontig összeköttetési szolgáltatást, amely a légiforgalmi szolgálatok között a biztonságos és hatékony ellátás alátámasztásához szükséges, az alábbiak között:

1) a légijármű fedélzeti rendszerek és a földi rendszerek; valamint

2) az összetett földi rendszerek között;

c) olyan adat-összeköttetési szolgáltatást nyújt, amely alkalmas a felhasználók biztonsági és biztonságossági követelményeinek teljesítésére;

d) nemzetközileg elismert adat-összeköttetési szabványokon alapul, amely meg fogja könnyíteni a jól alkalmazkodó rendszerek fejlesztését, és támogatja a versenyképes hálózati szolgáltatás biztosítását;

e) eltérő szolgáltatási típusokat/kategóriákat/osztályokat foglal magába (beleértve az előnyben részesített/kiválasztott levegő-föld alhálózatokat), olyanokat, amilyeneket a különböző alkalmazások megkívánnak;

f) meghatároz egy olyan felépítést, ami lehetővé teszi a nyilvános és a magán alhálózatok integritását, mind a levegő-föld, mind a föld-föld összeköttetésekre. Ez lehetővé teszi a meglévő/tervezett infrastruktúra és hálózati technológia felhasználását, valamint megadja a kivitelezőknek a hálózat méretének
megvalósításához úgy, hogy a növekvő felhasználói igények kielégíthetőek; és

g) hatékonyan használja fel a sávszélesség korlátozott levegő-föld alhálózatot és annak megfelelően csökkenti a költségeket.

3.2.3 A jelenleg meghatározott Légiforgalmi Távközlési Hálózati /ATN/ alkalmazások úgy kerültek kidolgozásra, hogy biztosítják a légiforgalmi összeköttetéseket, a légtérellenőrzést és a tájékoztató szolgálatokat. Ezek az alkalmazások a következő légiforgalmi szolgáltatás szervezési feladatok alátámasztására szolgálnak:

a) Légiforgalmi szolgálatok (ATS);

1) Légiforgalmi irányító szolgálat (ATC);

2) Repülés-tájékoztató szolgálat (FIS); és

3) Riasztó szolgálat;

b) Légiforgalmi áramlás-szervezés (ATFM); és

c) Légtér-szervezés.

3.2.4 Ez a fejezet a Légiforgalmi Távközlési Hálózat /ATN/ átfögó és általános előírásait foglalja magába. A részletes műszaki előírások a Doc 9705-ben találhatók. Ennek a fejezetnek a fennmaradó része a következő követelmények és funkciók ismertetéséhez szervezett:

a) általános;

b) rendszerszint követelmények;

c) ATN alkalmazási követelmények;

d) ATN összeköttetési szolgáltatási követelmények;

e) ATN elnevezés és címzés;

f) ATN rendszer kezelési követelmények; és

g) ATN biztonsági követelmények.

3.3 ÁLTALÁNOS RÉSZ

3.3.1 A Légiforgalmi Távközlési Hálózat (ATN) adat-összeköttetési szolgáltatást és alkalmazási entitásokat kell biztosítania az alábbiak alátámasztására:

a) a Légiforgalmi szolgálatok (ATS) közvetítése a légijárművek részére;

b) ATS információk cseréje az ATS egységek között; és

c) egyéb alkalmazások, mint például repülés-üzemi járatói felügyelet (AOC) és légiforgalmi igazgatási közlemény-váltás (AAC).

1. Megjegyzés. – Gondoskodni kell az olyan információ-csere befogadásáról, mint például az dőjárás, a repülési tervek, a NOTAM-ok és a tényleges valós-idejű légiforgalmi áramlás-szervezés a légijárműveket üzemeltető ügynökségek /járatók/ földi-bázisú rendszerei és az ATS egységek között.

2. Megjegyzés. – Gondoskodni kell a légiutasok összeköttetési (APC) rendszerének befogadásáról is.

3.3.2 Amikor az ATN-t a légiforgalmi szolgálatok alátámasztására használják, akkor meg kell, hogy feleljen az ebben a fejezetben lévő előírásoknak.

3.3.3 A Légiforgalmi Távközlési Hálózat /ATN/ használatára vonatkozó követelményeket a körzeti léginavigációs egyezmények alapján kell előírni.

3.3.4 **Ajánlás.** – *A polgári repülési hatóságoknak kell koordinálni a nemzeti hatóságokkal és a légiforgalmi berendezés gyártó iparral azokat a Légiforgalmi Távközlési Hálózati /ATN/ kivitelezési szempontokat, amelyek lehetővé fogják tenni az ATN világméretű biztonságát, együttműködő-képességét és hatékony felhasználását, ahogy megfelelő.*

3.4 RENDSZERSZINT KÖVETELMÉNYEK

Megjegyzés. – A rendszerszint követelmények magasszintű műszaki követelmények, amelyek az üzemeltetési követelményekből, a technológiai korlátozásokból és szabályozási korlátozásokból (adminisztratív és intézményi) származtattak. Ezek a rendszerszint követelmények képezik az alapját a funkcionális követelményeknek és az alacsonyabb szintű követelményeknek.

3.4.1 Az ATN-nél a Nemzetközi Szabványügyi Szervezetnek (ISO) a Nyílt rendszerek összekapcsolására (OSI) vonatkozó szabványait kell alkalmazni.

3.4.2 Az ATN-nek egy eszközt kell biztosítani az átmenet megkönnyítéséhez az alkalmazás entitások és/vagy az összeköttetési szolgáltatások jövőbeli változataihoz.

Megjegyzés. – Az a cél, hogy a jövőbeli változatok felé történő fejlődés a visszafelé való kompatibilitást az előző változatokka biztosítsa.

3.4.3 Az ATN-nek ehetővé kell tennie a jelenlegi AFTN/CIDIN felhasználók és rendszerek átmenetét az ATN felépítésbe.

Megjegyzés. – Az AFTN-ről vagy a CIDIN-ből az átmenet a Légiforgalmi Távközlési Hálózatba /ATN/ azok az AFTN/AMHS és a CIDIN/AMHS kapuk kezelik /AMHS= Légiforgalmi Szolgálatok Közlemény-kezelő Szolgáltatás/ külön-külön, amelyek a Doc 9705, III. Al-kötetében vannak meghatározva.

3.4.4 Az ATN-nél olyan intézkedéseket kell hozni, amelyek által csak az irányító Légiforgalmi Szolgálati /ATS/ egység adhat Légiforgalmi irányítási /ATC/ utasításokat a légtérben üzemelő légijárművek részére.

Megjegyzés. – Ez a légiforgalmi irányító és a légijármű-vezető közötti digitális adatcsere (CPDLC) összeköttetés alkalmazási adat-kapcsolat entitás folyamatos adat-jogosultságon és a soronkövetkező egység adat-jogosultságon keresztül kerül elérésre.

3.4.5 A Légiforgalmi Távközlési Hálózatnak /ATN/ előre meghatározott továbbítási útvonal listán alapuló továbbítási útvonalakat kell biztosítani.

3.4.6 Az ATN-nek eszközt kell biztosítania ahhoz, hogy meghatározza azt, hogy az adat-összekötetést csak a felhasználó által meghatározott forgalom fajtához és kategóriához jogosított útvonalon keresztül lehessen végrehajtani.

3.4.7 Az ATN-nek ATSC osztályzatot kell felkínálnia a 3-1.* táblázatban lévő követelményekkel összhangban.

* Az összes táblázat a fejezet végén került elhelyezésre.

1. Megjegyzés. – Amikor egy Légiforgalmi Távközlési Hálózati /ATN/ alkalmazás meghatároz egy ATSC osztályzatot, akkor az adat-csomagot az ATN internet összeköttetési szolgálatba "a legjobb erőfeszítési alapon" kell elküldeni. A "legjobb erőfeszítési alap" azt jelenti, hogy amikor egy útvonal az ATSC osztály részére rendelkezésre áll, akkor az adat-csomagot azon az útvonalon kell továbbítani. Amikor az ilyen továbbítási útvonal nem áll rendelkezésre, akkor az adat-csomagot az első olyan ismert útvonalon kell továbbítani, amelynek az ATSC osztályzata magasabb a kért útvonalnál, vagy ha nincs ilyen útvonal, akkor az ATSC osztályzatnál a kértnél alacsonyabb első ismert útvonalon kell továbbítani.

2. Megjegyzés. – Az ATN összeköttetési szolgálat nem fogja tájékoztatni az alkalmazási entitásokat akkor, ha a kért ATSC osztály nem volt elérhető. Az alkalmazási entitás felelőssége az, hogy meghatározza azt a tényleges átviteli késedelmet, amelyet helyi eszközökkel, például idő-bélyegzéssel lehet megállapítani.

3.4.8 Az ATN-nek a 3-2. és 3-3. táblázatban meghatározott közlemény elsőbbségnek megfelelően kell működnie.

3.4.9 Az ATN-nek eleget kell tennie az alkalmazási információk cseréjének, amikor egy vagy több jogosult vonala rendelkezésre áll.

3.4.10 Az ATN-nek értesítenie kell a megfelelő alkalmazási folyamatot, amikor nem áll rendelkezésre jogosult vonala.

3.4.11 Az ATN-nek egy eszközt kell biztosítania ahhoz, hogy egyértelműen megcímezze az összes ATN végponti és közbenső rendszert.

3.4.12 A Légiforgalmi Távközlési Hálózatnak lehetővé kell tennie a közlemény vevője részére azt, hogy azonosítsa a közlemény feladóját.

3.4.13 Az ATN címzési és elnevezési tervének lehetővé kell tennie azt az Államok vagy a szervezetek számára, hogy a saját adminisztratív területeiken belül címeket és elnevezéseket jelöljenek ki.

3.4.14 Az ATN-nek fenn kell tartania az adat-összeköttetést az állandóhelyű és a mozgó szolgálati rendszerekkel.

3.4.15 Az ATN-nek biztosítania kell az ATN mozgó szolgálati hálózatával a kapcsolatot úgy, ahogy az ebben az Annex-ben meghatározásra került.

3.4.16 Az ATN-nek gondoskodnia kell arról, hogy hatékonyan felhasználja a korlátozott sávszélességű alhálózatokat.

3.4.17 Az ATN-nek lehetővé kell tennie azt, hogy egy légijármű fedélzeti közbenső rendszer összekapcsolásra kerüljön egy földi közbenső rendszerrel az együtt-futó mozgó szolgálati alhálózatokon keresztül.

3.4.18 Az ATN-nek lehetővé kell tennie azt, hogy egy légijármű fedélzeti közbenső rendszer összekapcsolásra kerüljön az összetett földi közbenső rendszerekkel.

3.4.19 Az ATN lehetővé kell tennie az alkalmazási entitások közötti címzés információk cseréjét.

3.4.20 A Légiforgalmi Távközlési Hálózatnak alá kell támasztania a Bejelentkezési Eljárás (CM) kezelési alkalmazást akkor, ha más levegő-föld alkalmazásokat is alátámaszt.

3.4.21 Az ATN-nek képesnek kell lenni a társ-társ alkalmazás összekapcsolására, fenntartására, felszabadítására és megszüntetésére a bejelentkezési eljárás (CM) alkalmazásnál.

3.4.22 Az ATN-nek képesnek kell lenni pártól-párig alkalmazás együttesek létrehozására, fenntartására, felszabadítására és megszüntetésére az automatikus függő légtérellenőrzés (ADS) alkalmazásnál.

3.4.23 Az ATN-nek képesnek kell lenni a társ-társ alkalmazás összekapcsolására, fenntartására, felszabadítására és megszüntetésére az légiforgalmi irányító-légijárművezető közötti digitális adatcsere (CPDLC) alkalmazásnál.

3.4.24 Az ATN-nek képesnek kell lenni a társ-társ alkalmazás összekapcsolására, fenntartására, és megszüntetésére az automatikus közel-körzeti tájékoztató szolgálat (ATIS) alkalmazásnál.

3.4.25 Az ATN-nek képesnek kell lenni a társ-társ alkalmazás összekapcsolására, fenntartására, felszabadítására és megszüntetésére az légiforgalmi szolgálatok közleményeit kezelő szolgáltatás (ATSMHS) alkalmazással.

3.4.26 Az ATN-nek képesnek kell lenni a társ-társ alkalmazás összekapcsolására, fenntartására, felszabadítására és megszüntetésére az ATS egyégek közötti adat-csere (AIDC) alkalmazásnál.

3.4.27 Ahol az ATN-en belül a napra a pontos időt használják, ott annak az Egyeztetett Világidőhöz (UTC) 1 másodpercen belüli pontosságúnak kell lenni.

Megjegyzés. – Az idő pontossági érték a meghatározott pontossági értéknek legfeljebb a kétszeresével egyenlő szinkronizációs hibát eredményezhet.

3.4.28 A végrendszernek gondoskodnia kell annak biztosításáról, hogy annak valószínűsége, hogy nem észlel egy 255 oktettes közleményt, amelyet a hálózatok közötti távközlési szolgáltatásban (internet) rossz helyre továbbított, nem továbbított, vagy elrontott, kisebb vagy egyenlő legyen 10^{-8}-nal közleményenként.

Megjegyzés. – Elfogadott az, hogy a Légiforgalmi Távközlési Hálózat alhálózatai biztosítják az adatok azon sérthetetlenségét, amely a rendszerszint követelménnyel összeegyeztethető.

3.4.29 Az ATN védelmi szolgálata ATN vég-rendszerének képesnek kell lennie arra, hogy a társ-végrendszer azonosságot hitelesítse, az alkalmazási közlemények forrását azonosítsa, és az alkalmazási közlemények adat-sértetlenségét biztosítsa.

Megjegyzés. – Az alkalmazás közlemények ebben az összefüggésben a Légiforgalmi Szolgálatokra /ATS/, rendszer kezelésre és az igazgatási szolgálatokra vonatkozik.

3.4.30 ATN földi és levegő-föld határvonal közbenső rendszer ATN védelmi szolgálatának képesnek kell lennie a társ-közbenső rendszer azonosságának hitelesítésére, a továbbítási útvonal információs forrásának hitelesítésére, és a továbbítási útvonal információk adat integritásának biztosítására.

3.4.31 Az ATN-nek képesnek kell lennie a társ-társ alkalmazás összekapcsolására, fenntartására, felszabadítására az igazgatási tájékoztatások közlemény-cseréjéhez kapcsolódóan.

3.4.32 Egy Légiforgalmi Távközlési Hálózat rendszer kezelést alátámasztó ATN rendszernek elő kell segítenie az ATN üzemeltetés fokozott folyamatosságát, beleértve az összeköttetési szolgáltatás ellenőrzését és minőségének fenntartását.

3.4.33 Az ATN-nek képesnek kell lennie a Rendszer kezelés (SM) alkalmazás össze- kapcsolására, fenntartására, felszabadítására és megszűntetésére a társ-társ alkalmazásokhoz kapcsolódóan.

3.4.34 Az ATN-nek képesnek kell lennie a repülési rutin időjárás-jelentő szolgálat (METAR) alkalmazás összekapcsolására, fenntartására, felszabadítására és megszűntetésére a társ-társ alkalmazásokhoz kapcsolódóan.

3.5 A LÉGIFORGALMI TÁVKÖZLÉSI HÁLÓZAT /ATN/ ALKALMAZÁSI KÖVETELMÉNYEI

1. Megjegyzés. – ATN alkalmazás(ok) megvalósítása egy Államon vagy egy körzeten belül nem vonja maga után az összes, az alábbiakban meghatározott ATN alkalmazás megvalósítását.

2. Megjegyzés. – Az ATN alkalmazásnak egy előre-meghatározott részegysége műszaki előírásainak megvalósítása úgy megengedett, ahogyan az a Doc 9705-ben részletesen meghatározott.

3.5.1 Rendszer alkalmazások

Megjegyzés. – Rendszer alkalmazások olyan szolgáltatásokat biztosítanak, amelyek a Légiforgalmi Távközlési Hálózat /ATN/ levegő-föld alkalmazásainak, föld-föld alkalmazásainak és/vagy az ATN összeköttetési szolgálatok működéséhez szükségesek.

3.5.1.1 A BEJELENTKEZÉSI ELJÁRÁS (CM) ALKALMAZÁS

Megjegyzés. – A Bejelentkezési eljárás /CM/ alkalmazás biztosítja egy légijármű részére azt a lehetőséget, hogy egy Légiforgalmi Szolgálati /ATS/ földi rendszerhez bejelentkezzen; bizonyos essetekben a földi rendszer fogja kérni a légijárműtől, hogy vegye fel az összeköttetést egy meghatározott földi rendszerrel. Miután a megfelelő kapcsolat létrejött, a Bejelentkezési eljárás /CM/ biztosítja az információ-cserét minden egyes alátámasztott ATN alkalmazás részére, beleértve az egyes hálózati címzéseket is, ahogy megfelelő. A védelmi szolgálatot alátámasztó ATN rendszerekre a CM biztosítja az adat-csere kulcsot és a kulcs kezelési információt is. A CM biztosítja még a bejelentkezési információ felfrissítésének lehetőségét is, és egy ATS földi rendszer részére azt a képességet, hogy továbbítsa a bejelentkezési információt egy másik ATS földi rendszerhez. A CM bejegyezteetési funkciója teszi lehetővé az információknak a földön vagy a légijárművön lévő további alkalmazásaival való megosztási lehetőséget.

3.5.1.1.1 A Légifogalmi Távközlési Hálózatnak képesnek kell lennie a következő Bejelentkezési eljárás /CM/ alkalmazási feladatok ellátására:

a) bejelentkezés;

b) kapcsolat felvétel;

c) adat-felfrissítés;

d) CM szerver lekérdezés;

e) CM szerver felfrissítés;

f) földi továbbítás; és

g) bejegyeztetés.

Megjegyzés. – A CM alkalmazásra vonatkozó műszaki előírások a Doc 9705, II. Alkötetében vannak meghatározva.

3.5.1.2 LÉGIFORGALMI TÁVKÖZLÉSI HÁLÓZAT /ATN/ KATALÓGUS SZOLGÁLTATÁS (DIR)

3.5.1.2.1 Az ATN-nek képesnek kell lennie a következő DIR alkalmazás funkciók alátámasztására:

a) katalógus összeállítás;

b) ja katalógus információ visszakeresése; és

c) a katalógus információ cseréje.

1. Megjegyzés. – Az ATN Katalógus Szolgáltatás lehetőséget biztosít egy alkalmazás vagy egy felhasználó részére, hogy lekérdezze az elosztott katalógus adatbázist és, hogy visszakeresse a címzési, védelmi és műszaki lehetőségi tájékoztatásokat. A Katalógus Szolgáltatás (DIR) lehetőséget biztosít a meghatározott és jogosított felhasználók részére, hogykiegészítsék, töröljék és módosítsák a katalógus adatbázis részeit, azokat amelyekért felelősek. A Katalógus Szolgáltatás az ATN-en keresztül az összes olyn alkalmazás és felhasználó részére "felajánlott", aki eleget tesz a Doc 9705, VII. Alkötet műszaki előírásainak.

2. Megjegyzés. – A katalógus hozzárendelés feladata az, hogy társítást hozzon létre két olyan katalógus összetevő között, amelyek a további katalógus funkciókat támasztják alá. A katalógus hozzárendelés állítja fel az alkalmazási összefüggést és az egyéb katalógus funkciók használatának összeköttetési kapcsolata alapjául szolgál.

3.5.1.3 EGYÉB RENDSZER ALKALMAZÁSOK

(Kidolgozás alatt)

3.5.2 Levegő-föld alkalmazások

Megjegyzés. – A levegő-föld alkalmazások földi összetevői foglalják magukba azokat a rendszereket, amelyek a levegő-föld közlemények tartalmát továbbítják a föld-föld összeköttetési vonalakon.

3.5.2.1 AUTOMATIKUS BERENDEZÉS-FÜGGŐ LÉGTÉR-ELLENŐRZŐ RENDSZER (ADS) ALKALMAZÁS

Megjegyzés. – Az ADS alkalmazást egy légijármű fedélzeti és egy földi rendszer alkotja. A légijármű fedélzeti ADS alkalmazási képes arra, hogy a Léégiforgalmi Távközlési Hálózat /ATN/ összeköttetési szolgálatán keresztül automatikusan továbbítsa a földi rendszer részére az adatokat a fedélzeti navigációs rendszerekből. (pl. légijármű azonosítót, a négy-dimenziós helyzetet, a szándékot és kiegészítő adatokat, ahogy szükséges). Az ADS alkalmazás a szolgáltatást azokon a kapcsolatokon keresztül biztosítja, amelyek a rendszer levegőbeni és földi egységei között létrejönnek (azaz igény kapcsolat, szakaszosan ismétlődő kapcsolat, esemény kapcsolat és kényszerhelyzeti kapcsolat) és a két ADS földi rendszer között (azaz a soronkövetkező egységgel való kapcsolat).

3.5.2.1.1 A Légiforgalmi Távközlési Hálózat-/ATN/-nek képesnek kell lenni a következő ADS alkalmazások alátámasztására:

a) igény kapcsolatok;

b) szakaszosan ismétlődő kapcsolatok;

c) esemény kapcsolatok;

d) kényszerhelyzeti kapcsolatok; és

e) a soronkövetkező egységgel való kapcsolatok

Megjegyzés. – A Berendezés-függő Automatikus Légtér-ellenőrző Rendszer /ADS/ alkalmazásra vonatkozó műszaki előírások a Doc 9705, II. Alkötetében vannak meghatározva.

3.5.2.2 LÉGIFORGALMI IRÁNYÍTÓ ÉS LÉGIJÁRMŰVEZETŐ KÖZÖTTTI DIGITÁLIS ADAT-KAPCSOLAT (CPDLC) ALKALMAZÁS

Megjegyzés. – A CPDLC alkalmazást egy légijármű fedélzeti és egy földi rendszer alkotja, és ezek lehetőséget biztosítanak az adat-kapcsolati összeköttetésekre a Légiforgalmi Szolgálati /ATS/ egységek és az irányításuk alatt álló légijárművek között és/vagy azon légijárművekkel, amelyek az irányításuk alá kerülnek. A CPDLC alkalmazás rendelkezik azzal a képességgel, hogy létrehozza, kezelje és befejezze a CPDLC dialógusokat a légiforgalmi irányító - légijárművezető közlemény-váltásokban és a földi közlemények továbbításában.

3.5.2.2.1 A Légiforgalmi Távközlési Hálózat-/ATN/-nek képesnek kell lennie az alábbi CPDLC alkalmazási funkciók alátámasztására:

a) légiforgalmi irányító - légijárművezető közötti közlemény-váltás;

b) az adat jogosultság átadása;

c) a soronkövetkező irányítási engedély kérése; és

d) adat-továbbítás a föld felé.

Megjegyzés. – A CPDLC alkalmazásra vonatkozó műszaki előírások a DOC 9705, II. Alkötetében vannak meghatározva.

3.5.2.3 REPÜLÉS-TÁJÉKOZTATÓ SZOLGÁLATI (FIS) ALKALMAZÁS

Megjegyzés. – A FIS alkalmazások repülés-tájékoztató szolgálatot biztosít a légtér felhasználók részére a földi FIS rendszerektől.

3.5.2.3.1 AUTOMATIKUS KÖZEL-KÖRZETI TÁJÉKOZTATÓ SZOLGÁLAT (ATIS) ALKALMAZÁS

3.5.2.3.1.1 A Légiforgalmi Távközlési Hálózat-/ATN/-nek képesnek kell lenni a következő ATIS alkalmazás funkciók alátámasztására:

a) légijármű által kezdeményezett FIS igény kapcsolatok;

b) légijármű által kezdeményezett FIS adat-felfrissítési kapcsolatok; és

c) mindkét irányú, mind a légijármű, mind a föld által kezdeményezett FIS kapcsolatok törlése.

Megjegyzés. – Az ATIS alkalmazásokra vonatkozó műszaki előírások a Doc 9705, II. Alkötetében vannak meghatározva.

3.5.2.3.2 REPÜLÉSI RUTIN IDŐJÁRÁS-JELENTÉSI SZOLGÁLAT (METAR) ALKALMAZÁS

3.5.2.3.2.1 A Légiforgalmi Távközlési Hálózat-/ATN/-nek képesnek kell lennie a légijármű által kezdeményezett FIS igény kapcsolat esetén a METAR alkalmazási funkció alátámasztására.

Megjegyzés. – A METAR alkalmazásra vonatkozó műszaki előírások a Doc 9705, II. Alkötetében vannak meghatározva.

3.5.2.3.3 EGYÉB FIS ALKALMAZÁSOK
(Kidolgozás alatt.)

3.5.2.4 EGYÉB LEVEGŐ-FÖLD ALKALMAZÁSOK
(Kidolgozás alatt.)

3.5.3 Föld-föld közötti alkalmazások

Megjegyzés. – A föld-föld közötti alkalmazások úgy vannak meghatározva, mint Légiforgalmi Távközlési Hálózati /ATN/ alkalmazások, az azokban a földi bázisú rendszerekben lévő azon alkalmazások, amelyek kizárólag csak azokkal a társ- alkalmazásokkal cserélnek információt, amelyek szintén a földi rendszerekben vannak.

3.5.3.1 KÖZPONTOK KÖZÖTTI DIGITÁLIS KÖZLEMÉNY-VÁLTÁS (IIC)

Megjegyzés. – A központok közötti digitális közlemény-váltás alkalmazások teszik lehetővé a légiforgalmi szolgálati egységek közötti információ-cserét.

3.5.3.1.1 LÉGIFORGALMI SZOLGÁLATI /ATS/ EGYSÉGEK KÖZÖTTI AUTOMATIKUS ADAT-CSERE (AIDC)

Megjegyzés. – Az AIDC egy olyan ATN alkalmazás, amely két légiforgalmi szolgálati egység között használatos a Légiforgalmi Szolgálati /ATS/ információk cseréjére: az aktív repülésre vonatkozó repülési jelentésekre, a repülés koordinációra, az irányítás átadására, a légtér-ellenőrzési adatokra és a szabad (szerkesztetlen) szöveg adatokra vonatkozóan.

3.5.3.1.1.1 A Légiforgalmi Távközlési Hálózat-/ATN/-nek képesnek kell lennie az alábbi AIDC alkalmazás funkciók alátámasztására:

a) repülési jelentések;

b) repülés koordináció;

c) az irányítás átadása;

d) az összeköttetés átadása;

e) a légtér-ellenőrzési adatok átadása; és

f) általános adatok átadása.

Megjegyzés. – Az AIDC alkalmazásra vonatkozó műszaki követelmények a Doc 9705. III. Alkötetében vannak meghatározva.

3.5.3.2 A LÉGIFORGALMI SZOLGÁLATOK /ATS/ KÖZLEMÉNY TOVÁBBÍTÁSI ELJÁRÁSAI (ATSMHS) ALKALMAZÁSOK

Megjegyzés. – Az ATS közlemény továbbítási eljárások (ATSMHS) alkalmazások egy fő funkciót foglalnak magukba, név szerint az ATS közlemény szolgáltatás funkciót. Az ATS közlemény szolgáltatási funkció lehetővé teszi azt, hogy a közlemények cseréje a szolgáltatás felhasználók között megtörténjen az általános közlemény szolgáltatások által. Az ATSMHS alkalmazás magába foglalja az AFTN/ATN és CIDIN/ATN kapuk meghatározását.

3.5.3.2.1 Az ATN-nek képesnek kell lenni az ATS közlemény továbbítási eljárásai (ATSMHS) alkalmazásban az ATS közlemény szolgáltatások alátámasztására.

Megjegyzés. – Az ATSMHS alkalmazásra vonatkozó műszaki követelmények a Doc 9705, III. Alkötetében vannak meghatározva.

3.5.3.3 EGYÉB FÖLD-FÖLD ALKALMAZÁSOK

(Kidolgozás alatt.)

3.6 AZ ATN TÁVKÖZLÉSI SZOLGÁLTATÁS KÖVETELMÉNYEI

Megjegyzés. – Az ATN Távközlési Szolgáltatás követelményei meghatározzák a Nyílt Rendszerek /OSI/ referencia model 3-tól 6-ig terjedő rétegei, valamint a 7. réteg egy része iránti követelményeket. Ezek a szolgálatok veszik át az egyes ATN alkalmazások által létrehozott egy-egy információt és hajtják végre a végponttól-végpontig összeköttetési szolgálat feladatát a szabvány protokolok felhasználásánál felhasználásával?. Ezek az összeköttetési szolgáltatási követelmények két részre vannak osztva. A felső réteg össze- köttetési szolgálatok határozzák meg a Szabványokat az 5-7 rétegre. Az 1. és 2. rétegekre vonatkozó követelmények az ATN Szabványok és Ajánlott Gyakorlatok /ATN SARPs/ tárgykörén kívül esnek.

3.6.1 Felső rétegű összeköttetési szolgáltatás

3.6.1.1 A felső réteg összeköttetési szolgáltatás magába kell, hogy foglalja:

a) a gyűjtő réteget;

b) a bemutató réteget;

c) az alkalmazási entitás szerkezetet;

d) az összekapcsolás irányító szolgálati elemet (ACSE);

e) a védelmi alkalmazás szolgáltatási célt (ASO) az ATN rendszert alátámasztó védelmi szolgáltatáshoz; és

f) vezérlő műveletet (CF).

1. Megjegyzés. – Az ATSMHS alkalmazás - az ATS közlemény szolgáltatási funkció kivételével - az összes ATN alkalmazás felső réteg össszeköttetési szolgáltatásra vonatkozó műszaki előírások a Doc 9705, IV. Alkötetében vannak meghatározva.

2. Megjegyzés. – Az ATSMHS alkalmazás ATS közlemény szolgáltatási funkcióra vonatkozó felső réteg összeköttetési szolgáltatás műszaki előírása a Doc 9705, III. Al- kötetében vannak meghatározva.

3.6.2 Légiforgalmi Távközlési Hálózat /ATN/ Hálózatok közötti távközlési szolgáltatás /Internet/

Megjegyzés. – Az ATN Internet szolgáltatási követelmények azokra a végponti rendszerekre és a közbenső rendszer funkcionális entitásaira alkalmazhatók, amelyek együtt az ATN Internet összeköttetési szolgáltatást biztosítják. Az ATN Inernet összeköttetési szolgáltatás a felhasználók részére (azaz a felső rétegekhez) a szállítási réteg szolgáltatás interfészen kresztül van biztosítva.

3.6.2.1 Az ATN vég-rendszernek (ES) képesnek kell lennie az ATN Internet alátámasztására, beleértve a:

a) szállítási réteget; és

b) a hálózati réteget is.

3.6.2.2 Egy ATN közbenső rendszernek (IS) eleget kell tennie az ATN hálózati réteg előírásoknak úgy, ahogy az érintett ATN közbenső rendszer megfelelő osztályzatának megfelel.

Megjegyzés. – Az ATN közbenső rendszer különböző osztályzatainak száma, amelyre a hálózat réteg profilok meg vannak határozva, a Doc 9705, V. Alkötetében találhatók.

3.7 A LÉGIFORGALMI TÁVKÖZLÉSI HÁLÓZAT /ATN/ ELNEVEZÉSI ÉS CÍMZÉSI KÖVETELMÉNYEI

Megjegyzés. – Az ATN elnevezési és címzési vázlat-tervezése támasztja alá az információs célok félreérthetetlen azonosításának alapelvét és a teljes címzési szabványosítást.

3.7.1 Az ATN-nek előírásokat kell biztosítani az alkalmazási réteg elnevezéséhez..

3.7.2 Az ATN-nek előírásokat kell biztosítani a hálózati és szállítási réteg címzéséhez.

Megjegyzés. – Az ATN alkalmazási réteg elnevezésére vonatkozó előírások a Doc 9705, IV. Alkötetében vannak meghatározva; a hálózati és szállítási címzésekre vonatkozó előírások az V. Alkötetben vannak meghatározva és a jegyzékbe vételi szolgáltatás a IX. Alkötetben került meghatározásra ugyanabban a dokumentumban.

3.8 A LÉGIFORGALMI TÁVKÖZLÉSI HÁLÓZAT /ATN/ RENDSZER KEZELÉSI KÖVETELMÉNYEK

1. Megjegyzés. – Az ATN rendszer kezelési (SM) alkalmazás biztosítja egy Rendszer kezelő /SM/ részére azt a lehetőséget, hogy információt cseréljen egy Rendszer kezelői /SM/ ügynökséggel és/vagy más rendszer kezelővel.

2. Megjegyzés. – Egy Légiforgalmi Távközlési Hálózat /ATN/ rendszer kezelési /SE/ szolgáltatások műszaki előírásainak alátámasztása egy Állami vagy körzeti alapon lehetséges.

3.8.1 Az ATN-nek képesnek kell lennie a következő rendszer kezelési alkalmazási funkciók alátámasztására:

a) Hiba kezelés;

b) Konfiguráció kezelés;

c) Forgalmi kezelés;

d) Teljesítmény kezelés; és

e) Védelmi kezelés.

Megjegyzés. – Az ATN Rendszer kezelésre vonatkozó műszaki előírások a Doc 9705, VI. Alkötetében kerültek meghatározásra.

3.8.1.1 Azoknak az ATN végponti rendszereknek és közbenső rendszereknek, amelyek az ATN rendszer kezelő alkalmazásokat alátámasztják és a rendszer kezelőknek /SM/ biztosítaniuk kell a kezelt adatokhoz való hozzáférést.

Megjegyzés. – A rendszer kezelési /SM/ alkalmazások kezelt céljainak meghatározását és a hozzáférési előírásokat a Doc 9705, VI. Alkötete határozza meg.

3.9 LÉGIFORGALMI TÁVKÖZLÉSI HÁLÓZAT /ATN/ BIZTONSÁGI KÖVETELMÉNYEK

3.9.1 Az ATN védelmét a műszaki előírások, a helyi fizikai biztonsági intézkedések és az eljárási biztonsági rendszabályok konfigurációjával kell elérni.

1. Megjegyzés. – Az ATN védelmére vonatkozó műszaki előírások a Doc 9705-ben vannak meghatározva és a fizikai, valamint az eljárási védelmi intézkedések az Annex 17-ben, illetve a Védelmi Kézikönyvben kerültek meghatározásra.

2. Megjegyzés. – Az ATN biztonsági szolgálatok műszaki előírásainak alátámasztására Állami vagy körzeti alapon lehet szükség.

3.9.1.1 **Ajánlás.** – *Az alábbi fizikai és eljárási technikákat lehet felhasználni az ATN végponti rendszerek, a közbenső rendszerek, al-hálózati kezelők, katalógus központi kiszolgáló egységek és al-hálózatok védelmének biztosításához:*

a) Korlátozott fizikai hozzáférés az ATN végponti rendszerekhez, közbenső rendszerekhez, SM munkaállomásokhoz, a katalógus központi kiszolgáló egységekhez és az alhálózati kapcsolókhoz, hálózati kezelőkhöz és a további alapvető hálózati alrendszerekhez;

b) Korlátozott felhasználói hozzáférés - csak feljogosított személyek részére - az ATN végponti rendszerekhez, közbenső rendszerekhez, katalógus központi kiszolgáló egységekhez, valamint az /SM/ munkaállomásokhoz; és

c) Az ATN földi végponti berendezések, a közbenső rendszerek és az SM munkaállomások táv-hozzáférésének megtiltása, vagy korlátozott hozzáférés biztosítása.

3.9.2 ATN biztonsági irányelvek

Megjegyzés. – Az összeköttetések ellenőrzése és a harmadik fél forgalmi elemzése nem jelent biztonsági veszélyt, és az ATS osztályzatra nem tekinthető biztonsági fenyegetésnek. Azonban néhány Légiforgalmi Szolgálati és/vagy nem-légiforgalmi szolgálati felhasználónak és alkalmazásnak lehetnek olyan helyi vagy szervezési irányelvei, amelyekben az összeköttetések ellenőrzését, valamint a harmadik fél forgalmazásának elemzését biztonsági fenyegetésnek tekinthetik egyéb vonatkozásokban, például gazdasági megfontolásokból.

3.9.2.1 A Légiforgalmi Szolgálatok /ATS/ közleményeit védeni kell a hibás megjelenítés, a módosítás és a visszajátszás ellen.

1. Megjegyzés. – Ez azt jelenti, hogy a Légiforgalmi Távközlési Hálózati /ATN/ entitások közötti adat-, közlemény-cseréknél magas szintű lesz annak a szavatossága, hogy a közlemény onnan jön, ahonnan azt igénylik, nem kerül meghamisításra és nem egy már elavult közlemény megismétlése.

2. Megjegyzés. – A védelem szintje a biztonság fenyegetésének típusa függvényében és a felhasználó vagy a felhasználói feldolgozás által kiválasztott ATN biztonsági szolgáltatási szint függvényében változó lehet.

3.9.2.2 Az ATS közlemények biztonságára vonatkozó kérést tiszteletben kell tartani.

Megjegyzés. – A biztonsdág mellőzése iránti kérés figyelembe vehető. Ez azt jelenti, hogyha a biztonság alkalmazása elmulasztásra kerül és a tárgyalás a mellőzésről a helyi irányelven alapszik.

3.9.2.3 Azokat az ATN szolgáltatásokat, amelyek légijárművekhez küldött és azoktól érkező közleményeket támasztanak alá, védeni kell a szolgáltatás visszautasítási támadásoktól olyan valószínűségi szintnek megfelelően, amely megegyezik a megkívánt alkalmazási szolgáltatás rendelkezésre állásának, ahogyan azt a helyi irányelvek meghatározzák.

1. Megjegyzés. – A "szolgáltatás visszautasítás" kifejezés azt a körülményt írja le, amikor az információkhoz és más ATN forrásokhoz való törvényes hozzáférés szándékosan akadályozva van.

2. Megjegyzés. – Ez jazt is elentheti, hogy egy alternatív összeköttetési útvonal rendelkezésre áll abban az esetben, ha az egyik útvonal szolgáltatási tilalomnak van alávetve.

TÁBLÁZATOK A 3. FEJEZETHEZ

3-1. táblázat. A Légiforgalmi Szolgálatokkal kapcsolatos összeköttetési osztályok átviteli késései

Maximális egy-utas ATN végberendezés-végberendezés átviteli késés 95 %-os valószínűséggel (másodperc)	*ATSC osztály*
Fenntartott	A
4,5	B
7,2	C
13,5	D
18	E
27	F
50	G
100	H
Nincs érték meghtározva	Nincs preferencia

1. Megjegyzés. - Az ATN végberendezéstől - végberendezésig átviteli késés körülbelül 90 %-át jelenti a rendszer végfelhasználói közötti végberendezéstől - végberendezésig tartó teljes késés értékének.

2. Megjegyzés. - A 95 %-os valószínűség a kért ATSC osztálynak megfelelő útvonal rendelkezésre állásán alapszik.

3-2. táblázat. A Légiforgalmi Távközlési Hálózat /ATN/ összeköttetési elsőbbségeinek jegyzéke

Közlemény kategóriák	*ATN alkalmazás*	*A megfelelő protokol elsőbbség*	
		Szállítási réteg elsőbbség	*Hálózati réteg elsőbbség*
Hálózat/rendszer kezelés	SM	0	14
Vészhelyzeti összeköttetések		1	13
Sürgősségi összeköttetések		2	12
Magas elsőbbségű repülés-biztonsági közlemények	CPDLC, ADS	3	11
Szabvány elsőbbségű repülés-biztonsági közlemények	AIDC, ATIS	4	10

Alacsony sürgős-ségű igazgatási közlemények és a légiutasok közleményei	0	0	Nem engedélye-zett	Nem engedélye-zett	Nem engedélye-zett	Nem engedélye-zett	Nem engedélyezett

1. Megjegyzés. – Az URH digitális adat-kapcsolat /VDL/ 2. Módnak nincs speciális al-hálózati elsőbbségi mechanizmusa.

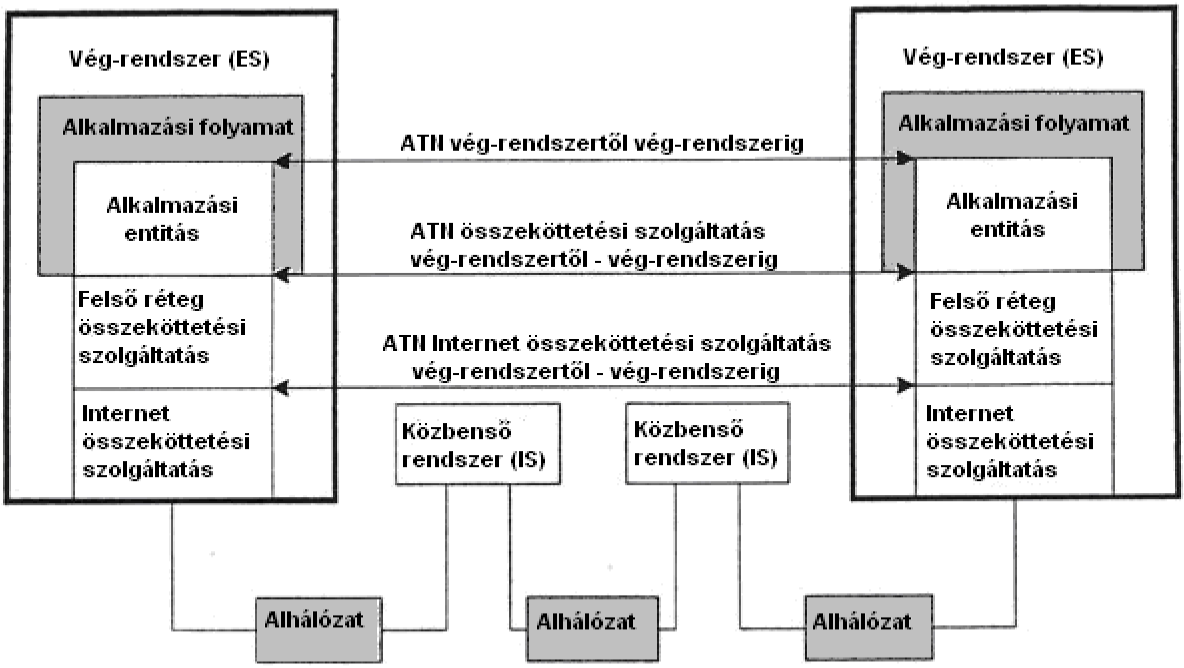
2. Megjegyzés. – A Légiforgalmi mozgó műholdas szolgálat /AMSS/ Szabványok és Ajánlott Gyakorlatok /SARPs/ anélkül határozzák meg az al-hálózat elsőbbségre a közlemény kategóriák jegyzékét, hogy határozottan utalnának az ATN hálózat réteg elsőbbségre.

3. Megjegyzés. – A „Nem engedélyezett" kifejezés azt jelenti, hogy csak a repülés biztonságára és rendszerességére vonatkozó közleményeknek a továbbítása engedélyezett ezen az al-hálózaton, ahogy azt az al-hálózat SARP-ja meghatározza.

4. Megjegyzés. – Csak azok a mozgó al-hálózatok kerültek jegyzékbe vételre, amelyekre al-hálózati SARP-ok vannak, és amelyekre határozott alátámasztást biztosítanak az ATN határvonal közbenső rendszer (BIS) műszaki előírásai.

5. Megjegyzés. - Az URH digitális adat-kapcsolat /VDL/ 4. Módú al-hálózat alátámasztást biztosít a légtér-ellenőrző alkalmazásokhoz (például Berendezés-függő Automatikus Légtér-ellenőrzés /ADS/).

ÁBRÁK A 3. FEJEZETHEZ



3-1. ábra:. A Légiforgalmi Távközlési Hálózat /ATN/ koncepcionális modelje

1. Megjegyzés. – Árnyékolás jelzi azokat az elemeket, amelyek ezeknek a Szabványoknak és Ajánlott Gyakorlatoknak /SARPs/ a tárgykörén kívül esnek. A felhasználói követelmény meghatározza az alkalmazás entitás és a felhasználó közötti kapcsolódást és biztosítja az ATN funkcionalitásának és együttműködésének biztosítását.

2. Megjegyzés. – Az ábra az ATN-nek egy egyszerűsített modelljét mutatja be, de nem szemlélteti az összes képességét (pl. a tárolási és továbbítási képességet, amely az ATS közlemény kezeléső szolgálata részére biztosítva van).

3. Megjegyzés. – Az ATN-en belül különböző vég-berendezéstől - vég-berendezésig pontok vannak meghatározva bizonyos vég-rendszertől - vég-rendszerig teljesítmény-követelmények meghatározására. Szükség lehet azonban ezektől eltérő vég- berendezéstől - vég-berendezésig pontok meghatározására ahhoz, hogy megkönnyítsék ezeknek a teljesítmény-követelményeknek való megfelelés minősítését. Ezekben az esetekben a vég-berendezéstől - vég-berendezésig pontokat világosan meg kell határozni és összefüggésbe kell hozni az ábrán bemutatott vég-rendszertől - vég-rendszerig pontokkal.

4. Megjegyzés. – Egy IS a funkcionalitásnak egy fogalmi képviselete, és nem tartozik pontosan egy továbbítási útvonalhoz. Egy olyan továbbítási útvonal-rendszer kezelő alkalmazást valósít meg, ami igényli a vég-rendszer protokoljait, és a rendszer kezelő alkalmazást használva, úgy is működik, mint egy vég-rendszer.

4. FEJEZET: LÉGIFORGALMI MOZGÓ-MŰHOLDAS SZOLGÁLAT (AMSS)

4.1 CSATORNA TÍPUSOK MEGHATÁROZÁSAI ÉS LEÍRÁSAI; ÁLTALÁNOS RÉSZ; RENDSZER-KÉPESSÉGEK

4.1.1 Csatorna típusok meghatározásai és leírásai

4.1.1.1. Meghatározások

Application. Alkalmazás. Egy információs rendszer végső felhasználása, magától a rend- szertől való megkülönböztetésként.

Aviation-BPSK. Repülési-BPSK /bináris fázis-billentyűzés (A-BPSK). A bináris fáziseltolás moduláció speciális formája, amelyet az AMSS-ben 2,4; 1,2 és 0,6 kbit/s csatorna átviteli sebességeknél használnak. Az A-BPSK egy olyan modulációs technika, amely a “0”-t a –90°-os fáziseltolódásra, és az “1”-et a + 90°-os fáziseltolódásra képezi le. A fázis-kódolt A-BPSK adatfolyamot ezt követően olyan szűrővel szűrik, amely kielégíti a 4. Fejezet 1. Függelékében lévő A1-1 és A1-2 táblázatokban meghatározott amplitúdó- és fázis versus frekvencia korlátokat.

Aviation-QPSK. Repülési-QPSK /kvaternes (négyes) fázis-billentyűzés/ (A-QPSK). Az offset négyes fáziseltolás moduláció speciális formája, amelyet a 2400 bit/s-nál nagyobb AMSS csatorna átviteli sebességeknél használnak. Az A-QPSK egy olyan modulációs technika, amely a “0”-t a 0 fokra és az “1”-et a “180”-fokra, vagy a “0”-t a 90 fokra és az “1”-t a 270-fokra képezi le váltakozva a két alternatíva között az egymást követő bitek alapján. A kódolt A-QPSK adatfolyamot ezt követően oly módon szűrik, hogy a modulált spektrum megfeleljen a 4. Fejezet 1. Függeléke A1-3 táblázatában meghatározottt amplitúdó-maszknak és az A1-2 táblázatban meghatározott fázismaszknak.

Burst. Impulzusköteg. Időegység által meghatározott, egy vagy több vonatkoztatott jel-egység szoros halmaza, amely felhasználói információkat és protokolokat, jelzéseket és valamilyen szükséges bekezdő jel-szakaszt szolgáltat.

Cyclic redundancy check. Ciklikus redundancia ellenőrzés. Minden jel-egység utolsó két byte-ja a teljes jel-egység ciklikus redundancia ellenőrzését végzi el a következők szerint. A hibajelzésre szolgáló ellenőrző biteket egy szabvány hosszúságú impulzus-egység első 10 oktettjéből vagy egy megnövelt hosszúságú impulzus-egység első 17 oktettjéből vagy az impulzusköteg azonosító első 4 oktettjéből vizsgálják a következő generátor polinom segítségével:
$x^{16} + x^{12} + x^5 + 1$

Megjegyzés. – Lásd a CCITT (Piros Könyv) X. 25. Ajánlás 2.2.7 szakaszát a számítási módszert és a bit sorrendet illetően.

Direct link service (DLS). Hibajavítás nélküli adat-kapcsolat (DLS). Adat összeköttetési szolgáltatás, amely nem kisérli meg az észlelt vagy nem-észlelt hibák automatikus helyesbítését a levegő-föld összeköttetési útvonal kapcsolati rétegében (a hiba ellenőrzést a vég-felhasználói rendszerekben végezhetik).

Epoch. Időköz. Egy esemény vagy egymással kapcsolatban álló események sorozatának kezdete és vége közötti, vagy élettartamára vonatkozó időtartam.

Frame. Keret. Egy struktúrált összeköttetési kapcsolat architektúra ismétlődő idő-szegmense, amely idő szerint számítható összeköttetési tevékenységeket biztosít az idő-szegmens kezdete és vége között.

Global beam. Globális sugárnyaláb. **M**űhold antenna irányítottság, amelynek fő nyalábja befogja a műhold látósugarában lévő teljes föld felületet.

Initial signal unit (ISU). Bevezető jel-egység (ISU). Az első jel-egység az egységek sorozatából, amelyet SSU-k követnek.

Link interface control infomation (LICI). Adat-kapcsolati réteg vezérlés (LICI). Vezérlés információ, amelyet a kapcsolati réteg és bármely szolgálatának felhasználója között az adat-kapcsolati réteg adat-egység (LIDU) részeként egymásközt cserélnek.

Link interface data unit (LIDU). Adat-kapcsolati réteg adat-egysége (LIDU). A teljes információ, amelyet egyetlen interakció kereten belül juttatnak keresztül a kapcsolati réteg és a kapcsolat szolgáltatás felhasználója közötti interfészen. Minden egyes LIDU tartalmaz összekötő interfész szabályozó információt (LICI) és ugyancsak tartalmazhat egy egyedi adat-kapcsolati réteg adat-egység (LSDU) elemet is.

Link service data unit (LSDU). Adat-kapcsolati réteg adat-egység elem (LSDU). Az adat-kapcsolati réteg adat-egység (LIDU) egy része és megegyezik az al-hálózat protokol adat-egységével (SNPDU).

Lone signal unit (LSU). Egyeddülálló jel-egység (LSU). Egyedüli jel, amely önmagában teljes közleményt képez.

Near-geostationary orbits. Közel-geostacionárius földkörüli pályák.A közel-geostacionárius földkörüli pályán üzemelő műholdak keringési ideje 24 óra, és az egyenlítői síktól való el- hajlásuk maximálisan 5 fok.

Network co-ordination station (NCS). Hálózat koordináló állomás (NCS). A teljes AMS(R)S rendszer lényegi része, amely a következő funkcionális kötelezettségeinek tesz eleget: a műholdas körzetén belül koordinálja a kommunikációs forgalmat és a műholdas összekapcsolhatóságot; és rendszerközti koordinációt lát el más műholdak által kiszolgált szomszédos műholdas körzetekkel.

P channel synchronization. P csatorna szinkronizációA P csatorna demodulátor állapota, amikor a P csatorna egyedi szavát megbízható módon érzékelik.

P channel degradation/loss. P csatorna teljesítmény-csökkenés/veszteség. Egy bejelentés, amelyet akkor adnak ki, amikor a P csatorna bit-hiba aránya egy 3 perces átlagoló időtartam alatt a 10^{-4} fölé emelkedik, vagy több mint 10 rövid idejű megszakítás (a P csatorna szinkronizációjának 10 másodpercnél rövidebb ideig tartó elvesztése) tapasztalható bármely 3-perces időtartamon belül; vagy amikor a P csatorna szinkronizáció 10 másodpercnél hosszabb időre elveszik.

Q number, Q level, Q precedence. Q szám, Q szint, Q elsőbbség. Egy közlemény vagy jelzéssorozat továbbítási sorrendiségének meghatározása, a 0 és 15 közötti számok alkalmazásával (először a 15-ös számot továbbítják).

Reliable link service (RLS). Megbízható adat-kapcsolati szolgáltatás (RLS). Egy, aműhold al-hálózat által biztosított olyan távközlési szolgáltatás, amely a hibaérzékeléssel és a hibásnak talált jel-egységek megismételt elküldésére irányuló kéréssel a kapcsolatában automatikus hibakezelést végez.

Satellite region. Műholdas körzet. Egy műhold látókörzetében található földrajzilag meghatározott részterület, amelyen belül e műhold szolgáltatásokat képes nyújtani.

Satellite service area. Műholdas szolgáltatási terület. Egy műhold látókörzetében található, földrajzilag meghatározott részterület, amelyen belül ez a műhold szolgáltatásokat nyújt. Figyelembe veendő, hogy egy műholdas szolgáltatási terület számos okból kifolyólg tovább osztható üzemeltetési műszaki jellemzők, feltételek és egyéb más korlátozó tényezők szerint.

Signal unit (SU). Jel-egység (SU). Ellenőrzésre és jelzésre, valamint felhasználói adat-csomag adat-átvitelre használt, időben rendezett, egymást követő adat-oktett együttesek. A P, T és C csatornákban használt szabvány hosszúságú SU-k 96 bitesek (12 oktett). Az R csatorna SU-k 152 bitesek (19 oktett), és a T csatorna 48 bites (6 oktett) fej-rész SU-t használ.

Spot beam. Irányított sugárnyaláb. Műhold antenna irányítottság, amelynek fő nyalábja a műhold látószögében lévő földfelületnél lényegesen kisebb területet fed be. Úgy is tervezhető, hogy tekintetbe véve a felhasználói földi állomások földrajzi megoszlását, javítsa a rendszer forrás-hatékonyságát.

Subsequent signal unit (SSU). A bevezető jel-egységet követő jel-sorozat. Az SU-k egy sorozatában a kezdeti jel-egységet követő jel-egység(ek).

Superframe. Szuperkeret. Adatátviteli keretek ismétlődő, időben struktúrált együttese, amely szuperkeret markert is tartalmaz (lásd még a "keret" meghatározásánál).

4.1.1.2 CSATORNATIPUSOK ISMERTETÉSE

4.1.1.2.1 *P csatorna.* Adat-csomag módozatú időosztásos multiplex (TDM) csatorna, amelyet folyamatosan továbbítanak a földi telepítésű földi állomásról (GES) a légijármű irányba, jelző- és felhasználói adatok vitele céljából. A rendszerkezelői funkciók céljára használt P csatorna jelölése P_{smc}, míg az egyéb funkciók elvégzésére használt P csatorna jelölése P_d. A P_{smc} és p_d funkciók szerinti jelölés nem feltétlenül alkalmazandó a különálló fizikai csatornákra.

4.1.1.2.2 *R csatorna.* Véletlen hozzáférésű (résidő kiosztásos Aloha) csatorna, amelyet a légijármű földi irányból, jelző- és felhasználói adatok átvitelére használnak. A rendszerkezelői funkciók céljára használt R csatorna jelölése R_{smc}, míg az egyéb funkciók elvégzésére használt R csatorna jelölése R_d. Az R_{smc} és R_d funkciók szerinti jelölés nem feltétlenül alkalmazandó a különálló fizikai csatornákra.

4.1.1.2.3 *T csatorna.* Rezervációs időosztásos muliplex hozzáférésű (TDMA) csatorna, amelyet csak a légijármű felőli irányból használnak. A vevő földi telepítésű földi állomás (GES) időréseket foglal le a légijármű fedélzeti földi állomások (AES) által igényelt adat-továbbítások számára a közlemény hosszúságának megfelelően. A küldő (AES) a lefoglalt időrésekben a prioritásnak megfelelően továbbítja a közleményt.

4.1.1.2.4 *C csatorna.* Áramkör üzemmódú egy csatorna per vivőfrekvenciás csatorna (SPC), amelyet mind a légijármű felőli, mind a légijármű felé tartó irányban használnak. Ez a csatorna időosztásos multiplexelt, az elsődleges csatorna hang vagy adat-forgalom szolgáltatás céljára, és az alsáv csatorna jelzés, ellenőrzés és adat közlemények szolgáltatásár használt. A csatorna használatát minden egyes művelet kezdetén és végén kijelölési és bontó-jelek szabályozzák.

4.1.2 Általános rész

4.1.2.1 Amikor közel-geostacionárius keringésű műholdakat használó légiforgalmi mozgó-hűholdas szolgáltatást (AMSS) hoznak létre és működtetnek a légiforgalmi szolgálatok segédeszközeként, annak meg kell felelnie a 4.1 - 4.10 pontok előíásainak.

4.1.2.2 Az AMSS berendezés kötelező jellegű felszerelésére vonatkozó követelményeket, ideértve a rendszer műszaki jellemzőinek szintjét, a körzeti léginavigációs egyezményekre alapozva kell kialakítani, amelyek meghatározzák a berendezés számára szolgáló üzemeltetési légteret, valamint a megvalósítási időskálákat.

4.1.2.3 A 4.1.2.1 pontban jelzett egyezmények legalább 2 éves határidőt kell, hogy biztosítsanak a fedélzeti rendszerek kötelező alkalmazására.

4.1.2.4 **Ajánlás.** – *A polgári repülési hatóságoknak a lehetőségek szerint egyeztetniük kell a nemzeti hatóságokkal és szolgáltatást biztosítókkal az AMSS megvalósításának azon szempontjait, amelyek lehetővé teszik az egész világon történő alkalmazhatóságát és optimális felhasználhatóságát.*

Megjegyzés. – Az AMSS használatára vonatkozó ICAO 24 bites légijármű címzések kiosztásának és kijelölésének előírásait a 9. fejezet tartalmazza.

4.1.3 Rendszer műszaki jellemzők

Megjegyzés. – A légiforgalmi mozgó-műholdas szolgálatot (AMSS) ellátó rendszer a légijármű földi állomásból (AES), a műholdból és a földi telepítésű földi állomásból (GES) áll. Az 1 (2, 3 vagy 4) szintű rendszer egy 1. (2, 3 vagy 4) szintű műszaki jellemzőkkel bíró AES-ből, egy vagy több műholdból, valamint egy vagy több olyan GES-ből áll, amely(ek) műszaki jellemzői biztosítják az AES összes műszaki jellemzőivel történő kompatibilis működést. Ilyen rendszerek többszörös szolgáltatásai egyidejűleg létezhetnek. A különböző rendszerek közötti együttműködés alapszintje biztosítva van.

4.1.3.1 *Hatáskör.* A rendszer műszaki jellemzőinek szintje kell, hogy magába foglalja az AES, a műhold és a GES teljesítményeit. Minimum feltételként az összes AES-nek rendelkeznie kell az 1. műszaki jellemzői képességű szinttel és a GES-hez való bejelentkezést követően folyamatosan figyelnie kell a P csatornát. Minden egyes GES-nek mindenkor, amikor AMS(R)S-t üzemeltet, rendelkeznie kell minimum feltételként 1. szintű műszaki jellemzőjű képességi szinttel.

4.1.3.1.1 Lenni kell egy P csatorna és egy R csatorna P_{smc} és R_{smc} műszaki jellemzőjű képességnek, amelyek minden egyes műholdas szolgálati terület részére rendszer-vezérlési funkciókat biztosítanak.

4.1.3.1.2 Abban az esetben, amikor egy adó csatornát osztanak meg az R és T csatornák között, az R csatorna adásait, amikor az csak szükséges, késleltetni kell a T csatornán folyó adás megszakításának elkerülése céljából.

4.1.3.2 *Az 1. szint*. Az 1. szintű műszaki jellemzőkkel rendelkező AES-nek a következő műszaki jellemzőjű képességekkel kell rendelkeznie:

a) egy P csatornán történő adat-fogadás és adat-feldolgozás a 0,6 és 1,2 kbit/s csatorna átviteli sebességgel; és

b) egy R és egy T csatornán történő adat-feldolgozás és adat-továbbítás a 0,6 és 1,2 kbit/s csatorna átviteli sebességgel.

Az R és a T csatornán folyó egyidejű átviteleket nem kell megkövetelni.

4.1.3.2.1 Az 1. szintű műszaki jellemzőkkel rendelkező légijármű fedélzeten elhelyezett földi állomás-/AES/-nek a földi telepítésű földi állomás-/GES/-hez történő bejelentkezés után folyamatosan tudnia kell fogadni és feldolgozni a P csatornát az AES-nek címzett közlemények vételének és a GES által adott parancsokra való reagálások biztosítása céljából.

4.1.3.2.2 **Ajánlás.** – *Az 1. szintű műszaki jellemzőjű képességekkel rendelkező AES-nek rendelkeznie kell a 4.1.3.2 pontban a kiegészítő 2.4 kbit/s csatorna átviteli sebesség számára meghatározott műszaki jellemzőkkel.*

Megjegyzés. – Az 1. szintű műszaki jellemzőjű képességekkel rendelkező AES a nyílt rendszerek összekapcsolásán alapuló alapvető adat-csomag összeköttetést végez a légi közlekedés összeköttetéseinek biztonságos ellátása céljából. Az 1. szintű műszaki jellemzőkkel rendelkező AES egy vevő- és egy adó-csatornát követel meg.

4.1.3.3 *A 2.szint.* A 2. szintű műszaki jellemzőkkel rendelkező AES-nek a következő műszaki jellemzőkkel kell rendelkeznie:

a) egy P csatornán történő adat-fogadás és adat-feldolgozás a 0,6 és 10,5 kbit/s csatorna átviteli sebességekkel; és

b) egy R és egy T csatornán történő adat-feldolgozás és adat-továbbítás a 0,6 és 10,5 kbit/s csatorna átviteli sebességekkel.

Az R és a T csatornán folyó egyidejű továbbításokat nem kell megkövetelni. A több mint egy P csatornán történő egyidejű vételt nem kell megkövetelni.

4.1.3.3.1 **Ajánlás.** – *A 2. szintű műszaki jellemző képességgel rendelkező AES-nek rendelkeznie kell a kiegészítő 4,8 kbit/s csatorna átviteli sebesség számára a 4.1.3.3 a) pontban meghatározott műszaki jellemzőkkel.*

4.1.3.4 *A 3. szint.* A 3. szintű műszaki jellemzőkkel bíró AES-nek a következő műszaki jellemzőkkel kell rendelkeznie:

a) 2. szintű műszaki jellemzőkkel rendelkező AES; és

b) egy, a C csatornán 8,4 vagy 21,0 kbit/s csatorna átviteli sebességű digitális információk vételét, feldolgozását és adását biztosító képességgel. A C csatorna akár R csatornával vagy T csatornával történő egyidejű működését nem kell megkövetelni.

4.1.3.4.1 **Ajánlás.** – *A 3. szintű műszaki jellemzőkkel bíró Légijármű fedélzetén elhelyezett földi állomás-/AES/-nek az 5,25; a 6,0 és a 10,5 kbit/s csatorna átviteli sebességeket kell biztosítania.*

Megjegyzés. – A 3. szintű műszaki jellemzőkkel bíró AES-nek a 2. szintű adat-csomag továbbítási módozaton felül digitalizált beszéd-üzemű képességet kell biztosítania a C csatornán. A kizárólagos hozzárendeléssel kapcsolatos követelményeket a 4.8 és a 4.9 szakaszok tartalmazzák. Két vevő- és egy adó-csatorna a követelmény.

4.1.3.5 *A 4. szint.* A 4. szintű műszaki jellemzőkkel bíró AES-nek a következő műszaki jellemzőjű képességekkel kell rendelkeznie:

a) 3. szintű műszaki jellemzőkkel bíró AES; és

b) egy C csatorna és egy R csatorna egyidejű működése; és

c) a C csatorna és a T csatorna egyidejű működése.

A három csatorna (C, R és T) egyidejű működését nem kell megkívánni.

4.1.3.5.1 **Ajánlás.** – *Egy 4. szintű műszaki jellemző képességekkelel bíró AES-nekt az 5,25; a 6,0 és a 10,5 kbit/s csatorna átviteli sebességeket kell biztosítania.*

Megjegyzés. – A 4. szintű műszaki jellemző képességekkel bíró AES digitalizált hang-képességeket biztosít a C csatornán és ezzel egyidejűleg adat-csomag mód adatátviteli képességekkel rendelkezik az R csatornán vagy a T csatornán. Két vevő- és két adó-csatorna megkövetelt.

4.1.3.5.2 **Ajánlás.** - *A 4. szintű műszaki jellemző képességekkel bíró AES-nek képesnek kell lenni az R és a T csatornán való egyidjű átvitelre akkor, amikor a C csatorna nincs hsználatban.*

4.2 SZÉLESSÁVÚ RÁDIÓFREKVENCIÁS JELLEMZŐK

4.2.1 Frekvenciasávok

4.2.1.1 AMS(R)S SÁVOK HASZNÁLATA

Megjegyzés. – A közlemények kategóriáti és a légiforgalmi mozgó (R) szolgálaton belüli egymáshoz viszonyított elsőbbségeiket az Annex 10, II. Kötet 5.1.8 pontja határozza meg. Ezek a kategóriák és elsőbbségek azonosan érvényesek a légiforgalmi mozgó (R) műholdas szolgáltatásra (lásd Nemzetközi Távközlési Unió /ITU/ Rádió-Szabályzat S44 Cikkely).

4.2.1.1.1 Minden egyes légijármű fedélzetén elhelyezett földi állomást és földön telepített földi állomást úgy kell tervezni, hogy biztosítható legyen az Annex 10, II. Kötet 5.1.8 pontjában meghatározott közleményeknek a 4.2.1.2 és 4.2.1.3 pontokban megállapított sávokon belüli frekvenciák vagy az állomás által hangolható frekvenciákat használó, más típusú közlemények adása és/vagy vétele általi késedelem elkerülése. Az Annex 10, II. Kötet 5.1.8 pontja által meg nem határozott közleményfajták szükség esetén figyelmeztetés nélkül megszüntethetők az Annex 10, II. Kötet 5.1.8 pontja által meghatározott közleményfajták adásának és vételének lehetővé tétele céljából.

Megjegyzés. – Lásd ITU Rádió-Szabályzat S5.357A sz.

4.2.1.2 LÉGIJÁRMŰHÖZ

4.2.1.2.1 A légijármű telepítésű földi állomásnak képesnek kell lennie az 1544-1555 MHz frekvenciasávban történő vételre.

Megjegyzés. – Az 1544–1545 MHz-es sáv mozgó műholdas szolgálat általi használata a vészhelyzeti és biztonsági üzemeltetésre van korlátozva.

4.2.1.2.2 **Ajánlás.** – *A légijármű telepítésű földi állomás legyen képes az 1555–1559 MHz frekvenciasávban történő vételre.*

Megjegyzés. – Az 1555–1559 MHz sávot az országok védetté tehetik és felhasználhatják nemzeti és nemzetközi AMS(R)S célokra.

4.2.1.2.3 **Ajánlás.** – *A légijármű telepítésű földi állomásnak ugyancsak képesnek kell lennie az 1525–1544 MHz frekvenciasávban történő vételre.*

Megjegyzés. – Az 1525–1544 MHz sáv felhasználható a tengeri mozgó-műholdas szolgálat állomásaival vészhelyzeti és nyilvános célokból történő közlemény-váltásokra az ITU Rádió- Szabályzat S41 Cikkelyével összhangban.

4.2.1.3 A LÉGIJÁRMŰTŐL

4.2.1.3.1 A légijármű fedélzetén telepített földi állomás legyen képes az 1645,5–1656,5 MHz frekvenciasávban történő adásra.

Megjegyzés. – Az 1645,5–1646,5 MHz-es sáv mozgó-műholdas szolgáltatás általi használata a vészhelyzeti és biztonsági üzemeltetésre korlátozott.

4.2.1.3.2 **Ajánlás.** – *A légijármű telepítésű földi állomás legyen képes az 1656,5–1660,5 MHz frekvenciasávban történő adásra.*

Megjegyzés. – Az 1656,5–1660,5 MHz sávot az Államok védetté tehetik és felhasználhatják nemzeti és nemzetközi AMS(R)S célokra.

4.2.1.3.3 **Ajánlás.** – *A légijármű telepítésű földi állomás legyen képes az 1626,5–1645,5 MHz frekvenciasávban történő adásra is.*

Megjegyzés. – Az 1626,5–1645,5 MHz sáv felhasználható a tengeri mozgó-műholdas szolgálat állomásaival vészhelyzeti és nyilvános célokból történő közlemény-váltásokra az ITU Rádió- Szabálxzat S41 Cikkelyével összhangban.

4.2.1.4 HANGOLÁSI NÖVEKMÉNYEK

4.2.1.4.1 A légijárműtől és a légijárműhöz irányú átvitel sávjaiban a csatornákat 2,5 kHz növekményekben kell kijelölni.

4.2.1.4.2 A légijármű telepítésű földi állomás csatorna kijelölését és hangolását a GES vezérlése alatt kell megvalósítani.

4.2.1.5 CSATORNA-SZÁMOZÁS

4.2.1.5.1 A csatorna-számot (Ct) a légijárműhöz irányú átviteli út középfrekvenciájának figyelembe-vételével kell meghatározni a következő képlet szerint:
Ct = (az adás frekvenciája (MHz) - 1 510,0)/0,0025

4.2.1.5.2 A csatornaszámot (Cf) a légijárműtől irányú átviteli út középfrekvenciájának figyelembe-vételével kell meghatározni a következő képlet szerint:
Cf = (az adás frekvenciája (MHz) - 1 611,5)/0,0025

4.2.2 Frekvencia pontosság

A légijármű telepítésű földi állomás adás-frekvenciája - ahogy az a műholdról vehető - nem térhet el a névleges csatorna-frekvenciától több mint ±383 Hz-el bármely ok következtében.

Megjegyzés. – Egy szubszonikus légijármű által vett adások frekvenciája nem térhet el a névleges csatorna-frekvenciától több mint ±2,18 kHz-el bármely ok következtében.

4.2.3 Légijármű fedélzetén elhelyezett földi állomások rádiófrekvenciás jellemzői

Megjegyzés. – A következő követelmények a teljes adás- és vételi frekvenciasávokra érvényesek.

4.2.3.1 ÁLTALÁNOS ANTENNA JELLEMZŐK

4.2.3.1.1 *Referencia fedésterület.* Az Antenna-rendszereket úgy kell felszerelni, hogy az adási és a vételi teljesítmény követelményeit kielégítsék egy 360 fokos oldalszogű és egy, a vízszintes síktól számított 5–90 fokos magassági szögek által meghatározott szintbeli repülést végző légijárművek részére.

4.2.3.1.1.1 **Ajánlás.** – *Az antenna-rendszereket a maximálisan lehetséges mértékig úgy kell felszerelni, hogy az adási és vételi teljesítmény követelményeket kielégítsék egy 360 fokos oldalszög és egy, a vízszintes síktól számított 5–90 fokos magassági szögeken belüli fedés légtérben +20/–5 fok bólintással és ±25 fokos bedöntéssel repülést végző légijárművek részére.*

4.2.3.1.2 *Polarizáció*. Az ITU Rádio-Szabályzat S1.154 sz. meghatározásának megfelelően a polarizációnak mind a vétel, mind az adás esetében jobbra-körkörösnek kell lennie.

4.2.3.1.3 *Antenna-kapcsolás.* Azoknak a légijármű telepítésű földi állomásoknak, amelyek egynél több antennát igényelnek, képesnek kell lenniük az ugyanazon antenna al-rendszerben lévő egyik antennáról a másik antennára való átváltásra, oly módon, hogy a jelmegszakítás ne legyen 40 ms-nál nagyobb.

Megjegyzés. – A 4.2.3.2, 4.2.3.2 bis *és a 4.2.3.3 pontok csak a nagy-, közepes- és kis-nyereségű antennákkal szemben támasztott követelményeket körvonalazzák. Ez nem zárja ki más nyereségű antennák jövőben történő bevezetését; egy ilyen bevezetés előtt elvégzendő megfontolások közül néhány az Annex 10, III. Kötet, I. Része A Mellékletében található útmutató anyagban került ismertetésre.*

4.2.3.2 KIS-NYERESÉGŰ ANTENNA AL-RENDSZEREK

4.2.3.2.1 *Nyereség-zaj hőmérsékleti viszonyszám.* Kis-nyereségű antennákat alkalmazó vevő al-rendszereknek el kell érniük a –26 dB/K-nél nem kisebb nyereség-zaj hőmérsékleti viszonyszámot (G/T) a 4.2.3.1.1 pontban meghatározott referencia fedés légtér nem kevesebb mint 85 szá- zalékában; és a –31 dB/K-nél nem kisebb nyereség-zaj hőmérsékleti viszonyszámot a fedés légtér fennmaradó 15 százalékában. Ez alól az egyedüli kivétel a horizontális síktól számított 70 foknál nagyobb magassági szögű régió, ahol a G/T nem lehet kevesebb, mint –28 dB/K.

4.2.3.2.2 *Axiális arány.* Az axiális arány kisebb kell, hogy legyen, mint 6 dB a 45 és 90 fok közé eső, és kisebb mint 20 dB az 5 és 45 fok közé eső magassági szögek esetében, vagy az AES antennának elegendő antenna-nyereséggel kell rendelkeznie az axiális arány által okozott veszteségen felüli további polarizációs veszteség kompenzálására. A kompenzáció figyelembevételekor azt kell feltételezni, hogy a műhold axiális aránya 2,5 dB, a polarizációs ellipszisek főtengelyei pedig ortogonálisak.

4.2.3.2.3 **Ajánlás.** – *A maximálisan lehetséges mértékig arra kell törekedni, hogy a G/T ne legyen kisebb, mint –26 dB/K és az axiális arány kisebb legyen, mint 6 dB a referencia fedés légtér 100 százalékában.*

4.2.3.2 *bis* KÖZEPES-NYERESÉGŰ ANTENNA AL-RENDSZEREK

Lásd 4.2.3.6 pontot.

4.2.3.3 NAGY-NYERESÉGŰ ANTENNA AL-RENDSZEREK

4.2.3.3.1 *Nyereség-zaj hőmérsékleti viszonyszám.* A nagy-nyereségű antennákat alkalmazó vevő al-rendszereknek el kell érniük a –13 dB/K-nél nem kisebb nyereség-zaj hőmérsékleti viszonyszámot (G/T) a referencia fedés légtér nem kevesebb, mint 75 százalékában és a –25 dB/K-nél nem kisebb nyereség-zaj hőmérsékleti viszonyszámot a 4.2.3.1.1 pontban meghatározott fedés légtér fennmaradó 25 százalékában.

4.2.3.3.2 *Axiális arány.* Az axiális aránynak kisebbnek kell lenni, mint 6 dB a 45 és 90 fok közé eső, és kisebb mint 20 dB az 5 és 45 fok közé eső magassági szögek esetében, vagy az AES antennának elegendő antennanyereséggel kell rendelkeznie az axiális arány által okozott veszteségen felüli további polarizációs veszteség kompenzálására. A kompenzáció figyelembevételekor azt kell feltételezni, hogy a műhold axiális aránya 2,5 dB, a polarizációs ellipszisek főtengelyei pedig ortogonálisak.

4.2.3.2.3 **Ajánlás.** – *A maximálisan lehetséges mértékig arra kell törekedni, hogy a G/T ne legyen kisebb, mint -26 dB/K és az axiális arány kisebb legyen, mint 6 dB a referencia fedés légtér 100 százalékában.*

4.2.3.3.4 *Megkülönböztetés. –* Az antenna-nyereségi alakzatnak, mind az adó-, mind a vevő-funkcióknál nem kevesebb, mint 13 dB-el kell különbséget tennie a 45 fok, vagy annál nagyobb földrajzi hosszúság eltéréssel rendelkező, venni kívánt és nem-kívánt műholdak irányai között, a 4.2.3.1.1 pontban meghatározott referencia fedés légtér nem kevesebb, mint 75 száza- lékában.

4.2.3.3.4.1 **Ajánlás.** – *Az antenna-nyereség alakzat mind az adó-, mind a vevőf-unkcióknál nem kisebb mint 13 dB-el tegyen különbséget a 45 fok vagy annál nagyobb földrajzi hosszúság eltéréssel rendelkező kívánt és nem-kívánt műholdak irányai között a 4.2.3.1.1 pontban meghatározott referencia fedés légtér 100 százalékában.*

4.2.3.3.5 *Fázis megszakítás.* Egy kapcsolt iránysugarú antenna szomszédos iránysugár helyzetei közötti iránysugár-vezérlés átmenetei a kisugárzott jelekben nem okozhatnak 12 foknál nagyobb RF fázis átmeneteket az összes szomszédos lehetséges iránysugár-kombinációk 99 százalékában.

4.2.3.3.5.1 **Ajánlás.** – *Egy kapcsolt iránysugarú antenna szomszédos iránysugár helyzetei közötti iránysugár-vezérlési átmenetei a kisugárzott jelben ne okozzanak 12 fokos továbbított jelnél nagyobb RF fázis átmenetet az összes szomszédos lehetséges iránysugár-kombinációk 100 százalékában.*

Megjegyzés. – Ez a követelmény az összes radar-rendszer esetében csak az egyedi antenna teljesítményre vonatkozik.

4.2.3.4 A VEVŐVEL SZEMBEN TÁMASZTOTT KÖVETELMÉNYEK

4.2.3.4.1 *A vevő hamis és lineáris teljesítménye.* A 4.4.2.3 és 4.4.5.4 pontokban meghatározott megkívánt teljesítményt úgy kell elérni, hogy a vevő antennát a maximális nyereség irányában megvilágítják egy, az 1525-1559 MHz sávban szétosztott –100 dBW/m^2 teljesítmény fluxus-sűrűséggel.

4.2.3.4.2 *A vevő átviteli sávon kívüli teljesítménye.* A 4.4.2.3 és a 4.4.5.4 pontokban meg- határozott megkívánt teljesítményt az átviteli sávon kívüli, a rendes üzemeltetési feltételekre jellemző szinteken fellépő interferencia jelenlétében kell elérni.

4.2.3.4.3 *Vételi fázis-zaj.* A vevő és a demodulátor olyan tervezésű kell, hogy legyen, hogy teljes egészében megfeleljenek azoknak a teljesítmény követelményeknek, amikor a vételi fázis-zaj karakterisztika nem haladja meg a 4-1. táblázatban* meghatározott maszk értékeit.

* Az összes táblázat ennek a fejezetnek a végén található.

4.2.3.4.4 *Befogadási tartomány.* A vevő képes kell, hogy legyen a jelek befogására és azok megtartására a névleges frekvenciától ±2,180 kHz-ig való frekvencia-eltéréssel a 4-2. táblázatban bemutatott vivőfrekvencia-zaj viszonynál.

4.2.3.4.5 *Vételi Doppler viszonyszám.* A vevő képes kell, hogy legyen a 4.3.3 pontban meghatározott teljesítmény befogására és megtartására a másodpercenkénti 30 Hz-es frekvencia fváltozási sebességgel.

4.2.3.5 AZ ADÓVAL SZEMBEN TÁMASZTOTT KÖVETELMÉNYEK

4.2.3.5.1 *EIRP /Izotrópikusan kisugárzott egyenértékű teljesítmény/ HATÁRÉRTÉKEK*

4.2.3.5.1.1 Kis-nyereségű antenna üzemeltetésekor a műhold irányába mutató vivőfrekvencia minimális EIRP értéke - a maximális beállításra állítva - 13,5 dBW kell, hogylegyen. A bármely irányban kisugárzott EIRP nem haladhatja meg a 22,8 dBW értéket.

4.2.3.5.1.1 *bis* Közepes-nyereségű antenna üzemelésnél a műhold irányába mutató vivőfrekvencia minimális EIRP értéke - a maximális beállításra állítva - 12,5 dBW kell, hogy legyen. A bármely irányban kisugárzott EIRP nem haladhatja meg a 34,8 dBW értéket.

4.2.3.5.1.2 Nagy-nyereségű antenna üzemeltetésekor a műhold irányába mutató vivőfrekvencia minimális EIRP értéke - a maximális beállításra állítva - 25,5 dBW kell, hogy legyen. A bármely irányban kisugárzott EIRP nem haladhatja meg a 34,8 dBW értéket maximális beállításban.

4.2.3.5.1.3 A maximális beállításnál kisebb beállítások esetében a bármely irányban kisugárzott vivőfrekvenciákkénti EIRP nem haladhatja meg a enni kívánt műhold felé kisugárzott EIRP-t 5 dB-nél nagyobb értékkel.

4.2.3.5.1.4 Több vivőfrekvenciás üzemelés esetén a megengedhető maximális üzemeltetési EIRP legyen az a szint, amelyen:

a) az aktív forrásokból származó teljes intermodulációs termék hozzájárulás a 4.2.3.5.7 pontban maximálisan megengedett (sávon belüli intermodulációs termékek), vagy

b) a nyereség-zaj hőmérsékleti viszonyszám a 4.2.3.2.1 vagy 4.2.3.3.1 pontban, meghatározott - aszerint, hogy melyik alkalmazható - a megengedett minimumként.

4.2.3.5.2 *EIRP vezérlés.* A venni kívánt műhold irányába mutató vivőfrekvenciánkénti EIRP a GES-től érkező utasítással egy 15 dB-es tartományon belül 1 dB-es fokozatonként állítható kell, hogy legyen.

4.2.3.5.3 **Ajánlás.** – *A teljesítmény-szabályozási tartomány minimális EIRP értékének a sáv átviteli sebesség és a műhold iránysugár jellemzők függvényének kell lennie - az interferencia lehetőség csökkentése céljából.*

4.2.3.5.4 *Lekapcsolt vivőfrekvenciás szint.* Az 1626,5–1660,5 MHz sávban összegezett, bármely irányba mutató EIRP, leállított vivőfrekvenciák esetén, legyen –24,5 dBW vagy kevesebb.

4.2.3.5.5 *EIRP bejelentkezés.* Egy Földi telepítésű földi állomás-/GES/-hez történő bejelentkezéskor a Légijármű fedélzetén elhelyezett földi állomás-/AES/-nek az EIRP-je legalább 13,5 dBW legyen.

4.2.3.5.6 *Sávon belüli hamis EIRP.* Modulált vivőfrekvencia bármely szinten, a maximálisan megengedhető üzemeltetési EIRP-ig történő átvitelénél az összetevő kisugárzott, egy 4 kHz sávra vonatkoztatott, sávon belüli hamis és zaj EIRP (intermodulációs termékek kizárva) nem haladhatja meg a –55 dBc értéket. Ez a követelmény nem vonatkozhat a 4.3.2.1 pontban meghatározott vivőfrekvencia középfrekvenciájának mindkét oldali frekvenciasávjára.

4.2.3.5.7 INTERMODULÁCIÓS TERMÉKEK

4.2.3.5.7.1 A többszörös vivőfrekvenciás AES esetén a kisugárzott intermodulációs termékek nem okozhatnak káros interferenciát a műholdas navigációs vevő működésében ott, ahol az ilyen vevő ugyanazon légijárművön üzemel, amikor két egyforma vivőfrekvenciát továbbít, amelyek teljes teljesítménye egyenlő az AES maximálisan megengedhető üzemeltetési EIRP-jével.

4.2.3.5.7.2 Az AES adó-vevő nem továbbíthat olyan újonnan kijelölt frekvencián, amely ötödrendű intermodulációs terméket állítana elő 1610,0 MHz alatti frekvencián.

4.2.3.5.7.3 Frekvencia kezelési eljárásokat kell használni az AES által sugárzott 1610 MHz alatti, ötöd- és annál alacsonyabb rendű intermodulációs termékek kiküszöbölésére.

4.2.3.5.8 *Sávon kívüli EIRP sűrűségi szintek.* Amikor bármely szinten egy vivőfrekvenciát sugároznak a 4.2.3.5.1 pontban meghatározott maximális teljesítményszintig, az AES által bármely irányba keltett hamis felharmonikusokat és zajt magában foglaló, sávon kívüli EIRP-je nem haladhatja meg a 4-3. táblázatban bemutatott szinteket.

4.2.3.5.8.1 **Ajánlás.** – *Az 1605–1610 MHz között az EIRP sűrűség nem haladhatja meg a –140 dBc/1 MHz értéket.*

4.2.3.5.9 *Fázis-zaj.* Egy modulált vivőfrekvencián indukált fázis-zaj teljesítmény spektrális sűrűség nem haladhatja meg a 4-4. táblázatban meghatározott tartományt.

4.2.3.5.10 *Az adó Doppler mértéke.* A sugárzott jel frekvencia változtatásainak maximális mértéke, amelyet a légijármű műhold irányába történő gyorsulásánál kompenzálnak, nem haladhatja meg a másodpercenkénti 15 Hz értéket. A Doppler szabályozási felbontása nem haladja meg a 10 Hz-et és a járulékos frekvencia változtatásokat a kisugárzott jel fázis-megszakítása nélkül kell elvégezni.

4.2.3.5.11 A Légiforgalmi mozgó-műholdas szolgálati /AMSS/ adások nem okozhatnak káros interferenciát a műholdas navigációs vevő működésében, ahol ilyen vevőt ugyanazon a légijárművön üzemeltetnek, mint az AES-t.

4.2.3.6 KÖZEPES-NYERESÉGŰ ANTENNA AL-RENDSZEREK

4.2.3.6.1 *Nyereség-zaj hőmérséklet viszonyszám.* Közepes-nyereségű antennákat alkalmazó vevő al-rendszerek el kell, hogy érjék a –19 dB/K-nél nem kisebb nyereség-zaj hőmérséklet viszonyszámot a

4.2.3.1.1 pontban meghatározott referencia fedés légtér nem kevesebb, mint 85 százalékán. Ez alól egyetlen kivétel az a körzet, amely több, mint 70 fokos magassági szögre van a vízszintes síktól, ahol a G/T nem lehet kisebb, mint –21 db/K.

4.2.3.6.2 *Axiális arány.* Az axiális aránynak 6 dB-nél kisebbnek kell lenni a 4.2.3.1.1 pontban hivatkozott referencia fedési légtér 85 százalékán, ahol a G/T-nek meg kell haladnia a –19 dB/K értéket, vagy az AES antennának elegendő nyereséggel kell rendelkeznie az axiális arány által okozott veszteségen felüli további polarizációs veszteség kompenzálására. A kompenzáció meglétéhez feltételezni kell, hogy a műhold axiális arányának 2,5 dB-nek kell lennie, merőleges polarizációs ellipszis főtengelyekkel.

4.2.3.6.3 **Ajánlás.** – *A G/T ne legyen kevesebb, mint –19 dB/K és az axiális arány legyen kevesebb, mint 6 dB a referencia fedési légtér 100 százalékán.*

4.2.3.6.4 *Megkülönböztetés.* Az antenna-nyereség alakzat mind az adó-, mind a vevő- funkcióknál 7 dB-nél nem kisebb mértékben tegyen különbséget a 80 fok vagy annál nagyobb földrajzi hosszúság-eltéréssel rendelkező venni kívánt és nem-kívánt műholdak irányai között a 4.2.3.1.1 pontban meghatározott referencia lefedési légtér 85 százalékán.

4.2.3.6.5 **Ajánlás.** – *Az antenna-nyereség alakzat mind az adó-, mind a vevő-funkcióknál nem kevesebb, mint 7 dB különbséget tegyen a 80 fok vagy annál nagyobb földrajzi hosszúság- eltéréssel rendelkező kívánt és nem-kívánt műholdak irányai között a 4.2.3.1.1 pontban meghatározott fedés légtér 100 százalékában.*

4.2.3.6.6 *Fázis megszakítás.* Egy kapcsolt iránysugarú antenna szomszédos sugárhelyzetei közötti sugár vezérlési átmenete a vevő és adó jelfázisában nem okozhatnak 30 foknál nagyobb RF fázis átmeneteket az összes lehetséges szomszédos sugár kombinációk 99 százalékában.

4.2.3.6.7 **Ajánlás.** – *Egy kapcsolt iránysugarú antenna szomszédos sugárhelyzetei közötti sugár vezérlési átmenetei a vett és a továbbított jelben nem okozhatnak 30 foknál nagyobb RF fázis-átmeneteket az összes lehetséges szomszédos sugár kombinációk 100 százalékában.*

4.3 RF CSATORNA MŰSZAKI JELLEMZŐK

4.3.1 Moduláció

4.3.1.1 *A 2.4 kbit/s és annál kisebb csatorna átviteli sebességek modulációja.* A 2,4; 1,2 és 0,6 kbit/s csatorna átviteli sebességek modulációjának reepülési bináris fázis-billentyűzésűnek kell lenni (A-BPSK).

4.3.1.2 *A 2,4 kbit/s és annál nagyobb csatorna átviteli sebességek modulációja.* A 2,4 kbit/s csatorna átviteli sebességnél nagyobb csatorna átviteli sebességek modulációjának repülési kvadratúra fázis-billentyűzésűnek kell lenni (A-QPSK).

4.3.2 *Kisugárzott teljesítmény spektrális sűrűség.* A következő kisugárzott teljesítmény spektrális sűrűség-határokat kell alkalmazni az adott irányban csúcs spektrális sűrűséghez normalizált bármely irányban. A határokat egy egyedi vivőfrekvenciára kell alkalmazni és a vivőfrekvenciában kell központosulniuk. Az alsó határ nem alkalmazható akkor, amikor az impulzus-köteg kezdetekor az AES a modulálatlan bevezető jel-szakaszt sugározza.

4.3.2.1 *A légijárműtől.* A Légijármű fedélzetén elhelyezett földi állomás /AES/ által sugárzott teljesítmény tartománynak a 4-5. táblázatban meghatározott maszk értékei közé kell esnie.

4.3.2.2 *A légijárműhöz.* Az AES által vett teljesítmény tartománynak az A-BPSK esetében a 4-6. táblázatban, az A-QPSK esetében a 4-7. táblázatban és a 4-7A. táblázatban meghatározott maszk értékei közé kell esnie.

4.3.3 *Demodulátor teljesítmény.* Ahol a csatorna átviteli sebességeket a 4.1 pontban meghatározottak szerint valósítják meg, az összezavart jelek megtisztítása után a csatorna demodulátorok bit hiba-arány (BER) teljesítménye legyen egyenlő vagy jobb a 4-8. táblázatban bemutatottaknál. Ezt a teljesítményt a következő feltételek szerint kell elérni:

a) a venni kívánt vivőfrekvencia bármelyik oldalán lévő két szomszédos interferáló vivőfrekvencia jelenlétében, amelyek a venni kívánt, a meghatározott névleges vivőfrekvencia tagolástól egy frekvencia bizonytalansággal eltérő vivőfrekvenciának a szintjénél 5 dB-lel nagyobbak, valamint az AES demodulátort illetően a maximálisan megengedhető üzemeltetési EIRP-ig történő működtetéssel;

b) a 4.2.3.5.9 pontban meghatározott maximális fázis-zaj műszaki jellemzőivel kisugárzott jel vétele alatt;

c) a másodpercenkénti sűrűséggel megjelenő 12°-os RF fázis megszakítások közben; és

d) Rician csatorna feltételek között 7 dB vivőfrekvencia több-utas viszonyszámú 20, 60 és 100 Hz elhalkuló sávszélességnél kis-nyereségű antennát, vagy kis- és nagy-nyereségű antennát használó rendszerek esetén;
vagy 10 dB csak nagy-nyereségű antennákat használó rendszerek esetén.

Megjegyzés. - A bit hiba teljesítmény célokat az AMS(R)S rádió-kapcsolatokra az ITU-R M.1037.sz. Ajánlás foglalja magába.

4.3.4 Rákapcsolódási teljesítmény

4.3.4.1 *A szuperkeret szinkronizáció eléréséhez szükséges idő.* Az utasítás kiadása és a műholdi szuperkeret szinkronizáció elvégzése céljából az antennára való kerülés közötti időperiódus nem haladhatja meg a 16 másodpercet.

Megjegyzés. – Ez azt feltételezi, hogy az AES ennek a P csatornának a műholdas szolgáltatási területén belül van.

4.3.4.2 **Ajánlás.** – *Az utasítás kiadásától a műhold szuperkeret szinkronizáció elvégzése céljából az antennára való kerülésig tartó időperiódus a lehető legrövidebb legyen.*

4.3.4.3 C-CSATORNA LÉGIJÁRMŰ FEDÉLZETÉN ELHELYEZET FÖLDI ÁLLOMÁS /AES/ DEMODULÁTOR BEFOGÁS

4.3.4.3.1 *21,0 KBIT/S CSATORNA ÁTVITELI SEBESSÉG*

4.3.4.3.1.1 *Keret befogás*. Az impulzus-köteg bevezető jelszakaszát követő első egyedülálló szónál a keret befogás sikertelenségének valószínűsége kisebb kell, hogy legyen, mint egy a 10^4-hez, beleértve a Gauss csatorna 1,2 dB-es E_s/N_0 értékénél a 4.3.3 a) és b) pontok feltételeit is; és a maximális bekezdő impulzus-köteg - bekezdő impulzus-köteg közötti ±30 Hz-es frekvencia bizonytalansággal, valamint a 4.4.5.1 pont alatti maximális csatorna átviteli sebesség pontossági eltéréssel.

4.3.4.3.1.2 *Téves keret befogás*. A téves keret befogás valószínűségének kisebbnek kell lennie, mint egy a 10^5-hez a Gauss csatorna 0 dB-es E_s/N_0 is, és a maximális bekezdő impulzus-köteg - bekezdő impulzus-köteg közötti ±30 Hz-es frekvencia bizonytalansággal, valamint a 4.4.5.1 pont alatti maximális csatorna átviteli sebesség pontossági eltéréssel.

4.3.4.3.1.3 *A keret befogás újra-megszerzése.* A keret befogás elvesztése esetén az újra- megszerzésnek 3 másodpercen belül kell megvalósulnia az idő 99 százalékánál, a Gauss csatorna 0 dB-es E_s/N_0 értékénél, belevéve a 4.3.3 a) és b) pontok feltételeit is, és a maximális bekezdő impulzus-köteg - bekezdő impulzus-köteg közötti ±30 Hz-es frekvencia bizonytalansággal, valamint a 4.4.5.1 pont alatti maximális csatorna átviteli sebesség pontossági eltéréssel.

4.3.4.3.2 *84 KBIT/S CSATORNA ÁTVITELI SEBESSÉG*

4.3.4.3.2.1 *Keret befogás*. Az első egyedülálló szónál a keret befogás sikertelensége valószínűségének kisebbnek kell lennie, mint egy a 10^3-ban a Gauss csatorna 4,1 dB-es E_s/N_0 értékénél, belevéve a 4.3.3 a) és b) pontok feltételeit is, és maximális bekezdő impulzus-köteg - bekezdő impulzus-köteg közötti ± 30 Hz-es frekvencia bizonytalansággal, valamint a 4.4.5.1 pont alatti maximális csatorna átviteli sebesség pontossági eltéréssel.

4.3.4.3.2.2 *Téves keret befogás*. A téves keret befogás valószínűségének kisebbnek kell lennie, mint egy a 10^4-hez a Gauss csatorna 4,1 dB-es E_s/N_0 értékénél, belevéve a 4.3.3 a) és b) pontok feltételeit is, és maximális bekezdő impulzus-köteg - bekezdő impulzus-köteg közötti ±30 Hz-es frekvencia bizonytalansággal, valamint a 4.4.5.1 pont alatti maximális csatorna átviteli sebesség pontossági eltéréssel.

4.3.4.3.2.3 *A keret befogás újra-megszerzése*. A keret befogás elvesztése esetén az újra- megszerzést 0,5 másodpercen belül kell megvalósítani az összes eset 90 százalékában, a Gauss csatorna 4,1 dB-es E_s/N_0 értékénél, belevéve a 4.3.3 a) és b) pontok feltételeit is, és a maximális bekezdő impulzus-köteg - bekezdő impulzus-köteg közötti ±30 Hz-es frekvencia bizonytalansággal, valamint a 4.4.5.1 pont alatti maximális csatorna átviteli sebesség pontossági eltéréssel.

4.3.4.4 C CSATORNA FÖLDI TELEPÍTÉSŰ FÖLDI ÁLLOMÁS /GES/ DEMODULÁTOR RÁKAPCSOLÓDÁS

4.3.4.4.1 *21,0 kbit/s csatorna átviteli sebesség*. Egy Gauss csatornánál és a 4.3.3 a) és b) pontok feltételei mellett ±600 Hz frekvencia eltolódással és ±0,5 Hz óra-frekvencia eltolódással az első egyedi szóra való keret befogás megvalósulása sikertelenségének a valószínűsége kisebb kell, hogy legyen 1,7 dB-es E_s/N_0 értékénél. A téves befogás valószínűségének kisebbnek kell lenni az egy a 10^5-hez az 1,7 dB-es E_s/N_0 értéknél. Amennyiben keret elvesztés történne, akkor azt 3,0 másod- percen belül újra meg kell szerezni a teljes idő 99 százalékában az 1,7 dB-es E_s/N_0 értéknél.

4.3.4.4.1. *bis 8,4 kbit/s csatorna átviteli sebesség.* Egy Gauss csatornánál a 4.3.3 a) és b) pontok feltételei mellett ±600 Hz frekvencia eltolódással és ±0,5 Hz óra-frekvencia eltolódással ez első egyedi szóra való keret befogás megvalósulása sikertelenségének a valószínűsége kisebb kell, hogy legyen, mint 1 a 10^3-hoz 4,4 dB-es E_s/N_0-nál. A téves befogás valószínűségének kisebbnek kell lenni, mint 1 a 10^4-hez 4,4 dB-es E_s/N_0-nál. Ha keret elvésztés történne, akkor azt 0,5 másod- percen belül újra meg kell szerezni a teljes idő 90 százalékában 4,4 dB-es E_s/N_0 értéknél.

4.3.4.4.2 *Egyéb C csatorna átviteli sebességek*. A GES demodulátor keret-kapcsolat sikertelen létrejötte valószínűségének kisebbnek kell lennie, mint egy a 10^2-hoz a C csatorna adásának kezdetétől számított 0,75 másodpercen belül.

4.3.4.4.3 **Ajánlás.** – *A GES demodulátor C csatorna keret-kapcsolat kialakításának a C csatorna adásának megkezdését követően a lehető leggyorsabban létre kell jönnie.*

4.4 CSATORNA-FORMÁTUM TÍPUSOK ÉS ÁTVITELI SEBESSÉGEK

4.4.1 Általános

4.4.1.1 *Légijármű rendszer-időzítő vonatkoztatási pont.* Az AES által gerjesztett és vett jelek vonatkoztatási időzítő pontja az antennánál kell, hogy legyen.

4.4.1.2 *Csatorna átviteli sebességek*. A csatorna átviteli sebességeknek, mint a 4.1.3 pontban meghatározott rendszer műszaki jellemzői szintjéhez alkalmazhatóak, a 4-9. táblázatban meghatározottaknak megfelelőeknek kell lenniük.

4.4.1.3 *Jel egységek (SU).* A P-, R-, T- és alsávi C-csatornákon keresztül továbbítandó összes információnak jel egység formátumúnak kell lennie. A P-, T- és alsávi C-csatorna jel egységeknek 96 bitből kell állniuk. Az R-csatorna minden jel egységének 152 bitből kell állnia. A jel egység formátumainak a 2. Függelékben meghatározottaknak megfelelőnek kell lenniük.

4.4.1.3.1 *Ciklikus redundancia ellenőrzés (CRC).* Minden egyes jel egység utolsó két bájtjának a jel egység ciklikus redundancia ellenőrzését kell szolgálnia. Bármely beérkezett jel egységet, amely nem felel meg a ciklikus redundancia ellenőrzésnek, figyelmen kívül kell hagyni.

4.4.1.3.2 *Jel minőség kiértékelés*. Az AES-nek az olyan információkat, mint a P-csatorna degradáció/veszteség és a C-csatorna bit hiba-aránya, az AES és a GES vezérlési funkciók rendelkezésére kell bocsátania, ahogy megfelelő.

4.4.2 P-csatorna

4.4.2.1 *Csatorna átviteli sebesség pontosság*. A csatorna átviteli sebesség hiba-aránya nem haladhatja meg az egy a 10^6-hoz értéket.

4.4.2.2 KERET FORMÁTUM

4.4.2.2.1 *Általános jellemzők*. Minden P-csatorna keretnek vagy 500 ms-nak, vagy az 500 ms többszörösének kell lenni azért, hogy egy 8 másodperces szuperkeret egyszerű leszármaztatását eredményezze, amit az R- és T-csatorna rés-idő kiosztására kell felhasználni. Minden egyes P-csatorna keretnek a következők szerint azonosított öt mezőből kell állnia: formátum azonosító, szuper-keret határ-jel, ál-mező (a 2,4 kbit/s-nál nagyobb adat sebességek részére), információs mező és egyedi szó, amint azt a 4-1*. ábra a 2,4 kbit/s és ennél kisebb, valamint a 4-2. ábra a 2,4 kbit/s-nál nagyobb csatorna átviteli sebességek esetére mutat be.

4.4.2.2.2 *Formátum azonosító*. Ennek a mezőnek a következő 4 bitből kell állnia: 0001. Egyéb értékek a jövőbeni alkalmazásokra vannak fenntartva.

4.4.2.2.3 *Szuper-keret határ-jel*. Ennek a mezőnek a következő 12 bitből kell állnia:
– 4 bit egy új szuper-keret kezdetének a jelzésére

1111 a 8 másodperces szuper-keret 0. kerete esetén

0000 a szuper-keret összes egyéb kerete számára

– 4 bit a szuper-keret keretének jelzésére

0000, 0001, 0010, 0011 a 0,6 kbit/s sebesség esetén

0000, 0001,…0111 az 1,2 kbit/s sebesség esetén

000,0000,…1111 a 2,4 kbit/s és nagyobb sebességek esetén

– 4 bit, amelyek az előző 4 bitet ismétlik.

4.4.2.2.4 *Ál-mező*. A 2,4 kbit/s feletti csatorna átviteli sebességek esetén ennek a mezőnek a következőnek kell lenni:

16 bitnek a 4,8 kbit/s sebesség esetén

178 bitnek a 10,5 kbit/s sebesség esetén.

* Az összes ábra a fejezet végén került elhelyezésre.

Az ál-mezőnek a 0001-ek sorozatából kell állnia, ahol a 0001 annyiszor ismétlődik, amíg a szükséges bitek számát elérrik.

Megjegyzés. – Az ál-mezőt azért alkalmazzák, hogy minden egyes keret 0,5 másodperc hosszúságú legyen. A 2,4 kbit/s és az az alatti adatátviteli sebességek esetében nincs szükség ál-mező alkalmazására.

4.4.2.2.5 *Információs mező.* Az információs mezőnek többszörös jel egységeket kell tartalmaznia, amelyeket rejtjeleznek, kódolnak és összesorolnak, ebben a sorrendben. Az információs mezőben található bitek számának a 4-10. táblázatban meghatározottaknak kell megfelelniük.

Megjegyzés. – Az információs mezőben található bitek száma az adatátviteli sebességtől és az információs mező összesoroló blokkjainak a számától függ.

4.4.2.2.5.1 *Rejtjelezés*. Egy 15 fokozatú rejtjelező generátor-regisztert kell alkalmazni az adatok vevő oldali hibajavításának (FEC) kódolása előtti rejtjelezésére. A rejtjelező és a rejtjel-megfejtő generátor-regiszterének polinomja $1 + X + X^{15}$ legyen. A rejtjelező és rejtjel-megfejtő óra-jelét az információs sebességre kell beállítani az első rejtjelezett bit első léptetés előtti kibocsátásával. Programozási parancsok hiányában a léptető regisztert a 1101 0010 1011 001 értékekre kell inicializálni (a léptető regiszter első fokozat legbaloldalibb bit) minden egyes keret információs mezejének kezdetekor. A rejtjelező és rejtjel-megfejtő funkcióknak a 4-3. ábrán bemutatottaknak kell lenniük. A rejtjelezőt minden egyes keret információs mezejének kezdetekor újra-inicializálni kell.

Megjegyzés. – A rejtjelező koncepció magyarázatát az ITU-R Ajánlások S.446-4, Annex I., Section 4.3.1 Method I. tartalmazza.

4.4.2.2.5.2 *Vevő oldali hibajavítás (FEC).* A 4.4.5.3.3.5.2 pontban szereplő szabványt kell alkalmazni.

Megjegyzés. – A P-csatornán nincsenek túlcsordulás bitek.

4.4.2.2.5.3 *Összesorolás.* Minden P-csatornának blokk összesorolást kell alkalmaznia. Az összesoroló oszlop mélysége (sorok száma) 64 adás-bit kell, hogy legyen, az oszlopok száma a 4-11. táblázatban szereplő adási sebességtől függő. Az adónál a konvolúciós kódoló kimenő adatait 64-bites oszlopokba kell írni, addig, amíg az előírt oszlopszám meg nem telik. Ezt követően a sorokat a $Row_j = (Row_i *27)$ modulo 64 algoritmus alkalmazásával permutálni kell. Ezt követően az összesoroló tartalmát sorról-sorra továbbítani kell a 4-4. ábra szerint. A vevő oldalon a demodulátorból érkező nyers döntési adatokat soronként be kell írni az összesorolóba, majd amikor az megtelik, az összesoroló sorait a $Row_j = (Row_i *19)$ moduló 64 átalakító algoritmus alkalmazásával permutálni kell. Ezt követően a nyers döntési adatokat oszloponként be kell olvasni a vevő oldali hibajavítás dekóderbe.

4.4.2.2.6 *Egyedi szó.* Az A-BPSK-nál minden P-csatorna keretnek a 32 bites 1110 0001 0101 1010 1110 1000 1001 0011 egyedi szóra kell végződnie, ahol a bal szélső bit kerül először továbbításra. Az A-QPSK-nál az egyedi szónak az A-BPSK egyedi szavának kell lenni, amelyet megismételnek minden azonos fázisú és kvadratúra csatornán.

4.4.2.3 *Teljesítmény.* A teljes fizikai szintet úgy kell konfigurálni és üzemeltetni, hogy az átlagos bit-hiba mérték 10^{-5}, vagy kisebb legyen a rejtjel-megfejtés után.

4.4.3 R-csatorna

4.4.3.1 *Csatorna átviteli sebesség pontossága.* A csatorna átviteli sebesség hiba-mértéke nem haladhatja meg az egy a 2R-ben értéket - ahol az R a csatorna átviteli sebesség - és az egy rész a 10^4-hez érték.

4.4.3.2 *Impulzus-köteg időzítés.* Minden egyes R csatorna impulzus-köteg kezdete meg kell hogy jelenjen a vett P-csatorna szuper-keret által meghatározott R-csatorna résének kezdete ±300 s-on belül. Amint azt a 4-5. ábra mutatja, minden P-csatorna szuper-keret meg kell hogy határozzon 8, 16, 32 és 64 véletlen elérésű rést a 0,6; 1,2; 2,4 és 10,5 kbit/s R-csatorna adatátviteli sebességek számára, hol az értékek a felsorolás sorrendje szerint tartoznak össze.

4.4.3.3 IMPULZUS-KÖTEG FORMÁTUM

4.4.3.3.1 *Általános jellemzők.* Minden egyes R-csatorna impulzus-kötegnek három mezőből kell állnia: bekezdő jel-szakasz, az egyedi szó és az információs mező, amint azt a 4-6. ábra mutatja.

4.4.3.3.2 *Bevezető jel-szakasz.* Az R-csatorna bevezető jel-szakaszának egy modulálatlan és az azt követő modulált részből kell állnia. Ezek hossza az adatátviteli sebességtől függ, amint azt a 4-12. táblázat mutatja. Az A-BPSK bevezető jel-szakasz modulálatlan része állandó fázisú jel kell, hogy legyen, és a modulált résznek a szabvány A-BPSK modulátorhoz bemenő váltakozó “0” és “1” értékekből kell állnia. A modulált rész első bitjének “0”-nak kell lennie és –90 fokos fázis-változást kell biztosítania a modulálatlan jel fázisához viszonyítva. Az A-QPSK bevezető jelszakasz modulálatlan részének egy olyan állandó fázisú jelnek kell lennie, amely megfelel egy olyan ideális A-QPSK modulátor kimenetének, amelynek bemenetén minden érték “0”. A modulált résznek váltakozó “0” és “1” (“0”-val kezdődően az első bitben) értékekből kell állnia az I. csatornán és folyamatos “0” értékekből a Q-csatornán.
Megjegyzés. – Szándék szerint a bekezdő jel-szakasz modulálatlan részét vivőfrekvencia akvizícióra, a modulált részét órajel akvizícióra kell használni.

4.4.3.3.3 *Egyedi szó.* A 4.4.2.2.6 pont alatti szabványt kell alkalmazni.

4.4.3.3.4 *Információs mező.* Minden R-csatorna bekezdő jelsorozat információs mezejének 160 bitből kell állnia, és tartalmazni kell egy kibővített jel-egységet, plusz 8 túlcsordulás bitet a konvolúciós kódolást megelőzően, ahol a kibővített jel-egységnek 152 bittel kell rendelkeznie és a túlcsordulás mezőnek 0000 0000-nak kell lennie. Az információs mezőt rejtjelezni, kódolni és összesorolni kell, ebben a sorrendben.

4.4.3.3.4.1 *Rejtjelezés.* A 4.4.2.2.5.1 pont alatti szabványt kell alkalmazni, azzal a kivétellel, hogy a túlcsordulás-bitek nem rejtjelezendők.

4.4.3.3.4.2 *Vevő-oldali hibajavítás (FEC) kódolás.* A 4.4.2.2.5.2 pont alatti szabványt kell alkalmazni azon kivétellel, hogy a kódolót minden impulzus-köteg információs mezejének kezdetekor az összes 0-ás állapotba kell újra-inicializálni.

4.4.3.3.4.3 *Összesorolás.* Az összes R-csatornának blokk összesorolást kell alkalmaznia. Az összesorolóban lévő sorok számának 64 átviteli bitnek, míg az oszlopok számának 5-nek kell lenni. Az összesorolóban lévő sorok felcserélését a 4.4.2.2.5.3 pont szerint kell végrehajtani.

4.4.3.4 *Teljesítmény.* A 4.4.2.3 pont alatti szabványt kell alkalmazni.

4.4.4 T-csatorna.

4.4.4.1 *Csatorna átviteli sebesség pontossága.* A csatorna átviteli sebesség hiba-mértéke nem haladhatja meg az egy a 2R-ben értéket - ahol R a csatorna átviteli sebesség - és az egy 10^{4}-hez érték.

4.4.4.2 *A P-csatornára vonatkozó időzítés.* Minden T-csatorna impulzus-köteg kezdetének a vett P-csatorna szuper-keret által meghatározott kijelölt T-csatorna rés kezdetétől számított ±300 s-on belül kell megjelennie. Amint azt a 4-7. ábra mutatja, minden P-csatorna szuper-keretet fel kell osztani egyenként 64 T-csatorna rést tartalmazó 16 névleges keretre. Két különböző légijármű T-csatorna impulzus-kötegei közötti legrövidebb őridő a GES vezérlése alatt áll és 5 résnyinek kell lennie.

4.4.4.3 IMPULZUS-KÖTEG SZERKEZET

4.4.4.3.1 *Általános jellemzők.* Minden T csatorna impulzus-kötegnek három mezőből kell állnia: a bevvezető szakasz, az egyedi szó és az információs mező, amint azt a 4-8. ábra mutatja.

4.4.4.3.2 *Bevezető jel-szakasz.* A 4.4.3.3.2 pont alatti szabványt kell alkalmazni.

4.4.4.3.3 *Egyedi szó.* A 4.4.2.2.6 pont alatti szabványt kell alkalmazni.

4.4.4.3.4 *Információs mező.* Minden T-csatorna impulzus-köteg információs mezejének tartalmaznia kell egy bekezdő szakasz azonosítót, "n" jel-egységet /SU/ és 16 túlcsordulás bitet a konvolúciós kódolást megelőzően, az alábbiak szerint:

Bekezdő szakasz azonosító – ez a mező 48 bitet tartalmaz, ami a kezdeményező légijárművet és a rendeltetési GES-t azonosítja.

n jel-egység – 2-től 31-ig terjedő, egyenként 96 bitből álló szabvány hosszúságú jel-egység, és

Túlcsordulás – 16 bitből álló mező (mindegyik 0) a konvolúciós kódoló kiürítésére.

Az információs mezőt rejtjelezni, kódolni és összesorolni kell, ebben a sorrendben.

4.4.4.3.4.1 *Rejtjelezés.* A 4.4.2.2.5.1 pont alatti szabványt kell alkalmazni, azon kivétellel, hogy a rejtjelezőt minden impulzus- köteg információs mezejének kezdetén újra-nicializálni kell.

4.4.4.3.4.2 *Vevő-oldali hibajavítás (FEC) kódolás.* A 4.4.2.2.5.2 pont alatti szabványt kell alkalmazni, azon kivétellel, hogy a konvolucíós kódolót minden impulzus-köteg információs keretének kezdeténél az összes 0 állapotába kell újra-inicializálni.

4.4.4.3.4.3 *Összesorolás.* Az összes T-csatornánál blokk összesorolást kell alkalmazni. Az összesorolóban lévő sorok számának 64 átviteli bitnek kell lenni, miközben az oszlopok száma a 4-13. táblázatban szereplő adatátviteli sebességtől kell, hogy függjön. Az adó-oldalon a konvolúciós kódoló kimenő jeleit 64 bites oszlopokba kell írni, amíg a meghatározott oszlopszám megtelik. Az összesoroló sorkicserélő algoritmusának összhangban kell állnia a 4.4.2.2.5.3 pont alattiakkal.

4.4.4.4 *Teljesítmény*. A 4.4.2.3 pont alatti szabványt kell alkalmazni.

4.4.5 C-csatorna

4.4.5.1 *Csatorna átviteli sebesség pontossága.* A csatorna átviteli sebesség hibamértéke nem haladhatja meg az egy a 2R-ben értéket, ahol R a csatorna átviteli sebesség, és az értéke egy a 10^4-hez.

4.4.5.2 ÁTVITELI FORMÁTUMOK

4.4.5.2.1 *Bevezető jelszakasz.* Az impulzus-köteg bevezető jelszakaszának az összes C-csatorna átviteli sebességnél - kivéve a 8,4 kbit/s csatornát - egy modulálatlan vivő részből és az azt követő modulált részből kell állnia. Ezek hosszúságának a 4-14. táblázatban szereplő csatorna átviteli sebességtől kell függnie, amint az alkalmazható a 4.1.3 pontban meghatározott rendszer műszaki jellemzőkre. A bevezető jelszakasznak a 4.4.3.3.2 pont és a 4-14. táblázat szövege szerintinek kell lennie. A 8,4 kbit/s csatornának nem lehet bevezető jelszakasza.

4.4.5.2.2 *BEFEJEZŐ JELSZAKASZ*

4.4.5.2.2.1 *8,4 kbit/s-os C-csatorna.* A C-csatorna befejező jelszakaszának váltakozva "1" és "0" értékekből ("1"-el kezdődően) kell állnia az I-csatornán és a Q-csatornán. A 8,4 kbit/s C-csatorna befejező jelszakasz hossznak egyenlőnek kell lennie 104 bittel.

4.4.5.2.2.2 *Az összes többi C-csatorna.* Az összes többi C-csatorna befejező jelszakaszának folyamatos "0"-kból kell állnia az I- csatornán és váltakozva "0" és "1"-ekből ("0"-val kezdődően) a Q-csatornán. A befejező jelszakasz hosszának egyenlőnek kell lennie egy egyedülálló összesoroló blokkal az összesorolós csatornák esetében, és 96 bittel kell egyenlőnek lennie az összesorolás nélküli csatornák esetében.

4.4.5.2.3 *A LÉGIJÁRMŰHÖZ*

4.4.5.2.3.1 *A 8,4 kbit/s-os C-csatorna.* A C-csatornának impulzus-köteg üzemmódban kell működnie a légijármű irányában. Ebben az üzemmódban a C-csatornának egy sorozat egymással szomszédos keretből kell állnia, amelyet egy befejező jelszakasz követ. Mindegyik keretnek két mezőből kell állnia: az egyedi szó és az információ mezőből, ahogyan azt a 4-9. *bis* ábra feltünteti. Mindegyik keretnek 500 ms hosszúságúnak kell lenni.

4.4.5.2.3.2 *Az összes többi C-csatorna.* Az összes többi C-csatornának impulzus-köteg üzemmódban kell működnie a légijárműhöz irányban. Ebben az üzemmódban a C-csatorna impulzus-kötegnek egy bevezető jelszakaszból kell állnia, amit egy sorozat egymással határos keret követ, ami után egy befejező jelszakasz következik. Minden keretnek három mezőből kell állnia: egy egyedi szóból, egy ál-mezőből és információs mezőből a 4-9. és a 4-10. ábráknak megfelelően. Minden keretnek 500 ms hosszúságúnak kell lennie.

4.4.5.2.4 *A LÉGIJÁRMŰTŐL*

4.4.5.2.4.1 *A 8,4 kbit/s-os C-csatorna.* A C-csatornának folyamatos üzemmódban kell működnie a légijármű felőli irányból. Ebben az üzemmódban a C-csatornának két mezőből kell állnia: az egyedi szó és az információs mezőből a 4-9. *bis* ábra szerint. Mindegyik keretnek 500 ms hosszúságúnak kell lenni.

4.4.5.2.4.2 *Az összes többi C csatorna.* Az összes többi C-csatornának folyamatos üzemmódban kell működnie a légijármű felőli irányból. Minden átvitelnek a 4.4.5.2.1 pontban meghatározott bevezető jelszakasszal kell kezdődnie. Ebben az üzemmódban a C-csatorna keretnek három mezőből kell állnia: az egyedi szóból, az ál-mezőből és az információs mezőből a 4-9. és a 4-10. ábra szerint. Minden keret hosszúságának 500 ms kell lennie.

Megjegyzés. - A P-, R- és T-csatornák információs mezői a vevő-oldali hibakorrekciós kódolás utáni információs bitekre vonatkoznak. A C-csatorna esetében az információs mező kódolást tartalmazhat is, meg nem is, a szóbanforgó C-csatorna típusától függően.

4.4.5.3 KERET FORMÁTUM

4.4.5.3.1 *AZ EGYEDI SZÓ*

4.4.5.3.1.1 *A 8,4 kbit/s-os C-csatorna.* Az egyedi szónak két 52 bites szakaszból kell állnia az A-QPSK jel
I- és Q-csatornáin:

I	1010	1011	0011	0111	0110	1001	0011	1000	1011	1100
	1010	0011	0000							
Q	0000	1100	0101	0011	1101	0001	1100	1001	0110	1110
	1100	1101	0101							

elsőként a bal-szélső bit továbbításával.

4.4.5.3.1.2 *Az összes többi C-csatorna.* Az A-QPSK jel I- és Q-csatornáin az egyedi szónak két azonos 44 bites sorozatból kell állnia: 0100 0010 1101 1010 1111 0011 0100 1011 1011 0001 0001, ahol a legbaloldalibb bit kerül először átvitelre.

4.4.5.3.2 *Ál-mező.* Ahol a csatorna átviteli sebességek a 4-9. táblázatban meghatározottak szerint és a 4-9., 4-9. *bis* és 4-10. ábrán bemutatottak szerint kerülnek alkalmazásra, az ál-mezőben lévő bitek számának a következőknek kell lenni:

- 62 a 10,1 kbit/s esetén;
- 44 a 21,0 kbit/s esetén;
- 37 az 5,25 kbit/s esetén; és
- 32 a 6,0 kbit/s esetén;
- 0 a 8,4 kbit/s esetén.

Az ál-biteknek az 5,25; 6,0; 10,5 és 21,0 kbit/s-os csatornáknál a 0101 1010 0011 1100 sorozatból kell állnia addig ismételve, amíg a szükséges bit számot el nem nyerik. A 8,4 kbit/s-os C-csatornánál egyetlen d3 bit van, amelyet a vevő-oldali hiba korrekció kódolása után adnak hozzá. A d3 bit értéke 1-re van állítva, ahogyan azt a 4-9. *bis* ábra mutatja.

4.4.5.3.3 *A KÓDOLT CSATORNÁK INFORMÁCIÓS MEZŐI*

4.4.5.3.3.1 A 8,4 kbit/s csatorna átviteli sebességnél ennek a mezőnek 4096 bitet kell tartalmaznia, amelyet 16 egyenként 256 bites összesoroló blokkra kell osztani. A 21,0 kbit/s csatorna átviteli sebességnél a mezőnek 10368 bitet kell tartalmaznia, amelyet 27 egyenként 384 bites összesoroló blokkra kell osztani.

4.4.5.3.3.2 **Ajánlás. -** *Az ajánlott 6,0 kbit/s csatorna átviteli sebesség esetén ennek a mezőnek 2880 bitet kell tartalmazni, ami egyenként 192 bitet tartalmazó 15 összesoroló blokkra van felosztva.*

4.4.5.3.3.3 *Az alsávi adatokat tartalmazó inormációs mező szerkezete.* A rejtjelezést, vevő-oldali hibajavítási (FEC) kódolást és összesorolást megelőzően az információs mezőnek egy kitöltő mezőből kell állnia, amit 25 váltakozó alsávi adat és átlátszó adat (hang) almező követ a 4-9. vagy 4-9. *bis* ábra szerint, ahogy megfelelő.

4.4.5.3.3.3.1 A 21,0 kbit/s csatorna átviteli sebesség esetén a kitöltő mezőnek 84 nullából kell állnia, minden almezőnek 12 alsávi adat bitet és 192 elsődleges bitet kell tartalmaznia, valamint a 25. alsávi adat almező utolsó 12 bitjét nullákkal kell kitölteni.

4.4.5.3.3.3.2 **Ajánlás.** - *Az ajánlott 6,0 kbit/s csatorna átviteli sebesség esetén a kitöltő mezőnek 40 nullából kell állnia, minden almezőnek 8 alsávi adat bitet és 48 elsődleges bitet kell tartalmaznia, valamint a 25. alsávi adat almező utolsó 8 bitjét nullákkal kell kitölteni.*

4.4.5.3.3.3.3 A 8,4 kbit/s csatorna átviteli sebességnél a kitöltő mezőnek egyetlen, 1-re állított értékű referencia bitből kell állnia, és mindegyik almezőnek 12 alsáv adat bitet és 96 elsődleges bitet kell tartalmaznia.

4.4.5.3.3.4 *Rejtjelezés.* A 4.4.2.2.5.1 pont alatti szabványt kell alkalmazni.

4.4.5.3.3.5 *Vevő-oldali hiba korrekció (FEC) kódolás*

4.4.5.3.3.5.1 *A 8,4 kbit/s-os C-csatorna.* A FEC egy k = 7-ben korlátozott hosszúságú, 2/3 mértékű lyukasztott konvolucíós kódolásból és egy nyers döntési Viterbi dekóderből áll. Ehhez a kódhoz tartozó generátor polinomok a következők legyenek:

G1: $1 + X^2 + X^3 + X^5 + X^6$

G2: $1 + X + X^2 + X^3 + X^6$

A kódoló bemeneti/kimeneti összefüggés: három kimeneti bit minden két bemeneti bithez, minden négy továbbított bit negyedik bitje elhagyásra kerül. A sorozat:

Bemeneti bit	1	2
Kimeneti sorozat	G_1 G_2	G_{-1}

4.5.3.3.5.2 *Egyéb C-csatorna átviteli sebességek.* Az információs mezőt az 1/2 mértékű vevő-oldali hibakorrekció kódolásra kell használni. A FEC kódolást egy 7-es hosszúságra korlátozott 1/2 mértékű konvolúciós kódolóval valósítják meg. A kódolt szimbólumok kimeneti sorozatának G1, G2-nek kell lennie (ahogyan a 4.4.5.3.3.5.1 pontban meghatározásra került és a 4-3. ábra bemutatja). A konvolúciót nem lehet keretek között iniciálni.

4.4.5.3.3.6 *Összesorolás*

4.4.5.3.3.6.1 Az összesorolóban a sorok számának 64 átviteli bitnek kell lenni. A 8,4 kbit/s csatorna átviteli sebességnél az oszlopok számának 4-nek kell lenni. A 21,0 kbit/s csatorna átviteli sebességnél az oszlopok számának 6-nak kell lenni.

4.4.5.3.3.6.2 **Ajánlás.** - *Az ajánlott 6,0 kbit/s csatorna átviteli sebesség esetén az összesorolóban lévő sorok számának 64 átviteli bitnek, és az összesoroló oszlopok számának 3-nak kell lenni.*

4.4.5.3.3.6.3 Az adónál a konvolúciós kódoló kimeneti jeleit 64 bites oszlopokba kell írni, amíg a meghatározott oszlopszám meg nem telik. Ezt követően a sorokat a 4.4.2.2.5.3 pontban meghatározott algoritmus szerint permutálni kell.

4.4.5.3.4 *A kódolatlan csatornák információs mezői.* Ahol a csatorna átviteli sebességeket a 4.1 pontban meghatározottak szerint alkalmazzák, ott a 10,5 kbit/s csatorna átviteli sebesség esetén ennek a mezőnek 5100 bitet, valamint az ajánlott 5,25 kbit/s csatorna átviteli sebesség esetén 2500 bitet kell tartalmaznia.

4.4.5.3.4.1 *Alsávi adatokat tartalmazó információs mező szerkezete.* A rejtjelezést megelőzően ezt a mezőt a 4-10. ábra szerint 25 váltakozó alsávi adat és elsődleges mezőre kell felosztani. Ahol a csatorna átviteli sebességeket a 4.1.3 pontban meghatározottak szerint alkalmazzák, ott a 10,5 kbit/s csatorna átviteli sebesség esetén minden almezőnek 12 alsávi adat bitet és 192 elsődleges bitet kell tartalmazni, a 25. alsávi adat almező utolsó 12 bitjét nullákkal kell kitölteni. Ahol a csatorna átviteli sebességeket a 4.1.3 pontban meghatározottak szerint alkalmazzák, ott az 5,25 kbit/s csatorna átviteli sebesség esetén minden almezőnek 4 alsávi adat bitet és 96 elsődleges bitet kell tartalmaznia, a 25. alsávi adat almező utolsó 4 bitjét nullákkal kell kitölteni.

Megjegyzés. – Az összesorolás nem alkalmazható a 10,5 és az 5,25 kbit/s csatorna átviteli sebességek esetében, mert ezeken a sebességeken az adatok nincsenek vevő-oldali hibakorrekció szerint kódolva.

4.4.5.4 *Teljesítmény.* A C-csatorna fizikai rétegét úgy kell konfigurálni és üzemeltetni, hogy az átlagos bit hibamérték 10^{-3} vagy kisebb legyen a rejtjel-megfejtést követően.

Megjegyzés. – A vett Bit hiba-arány-/BER/-nak a GES általi mérései lehetővé teszik a GES-nek az AES felé irányuló utasításai részére az AES kisugárzott teljesítményének szabályozását. A GES ugyancsak veszi az AES által készített teljesítmény adatmérési értékeket a GES kimenő teljesítménye beszabályozásának lehetővé tétele érdekében.

4.5 ADATKAPCSOLATI RÉTEG P-CSATORNA ÉS R-CSATORNA PROTOKOLOK

4.5.1 Általános

Megjegyzés. – A Légiforgalmi Mozgó-Műholdas Szolgálat /AMSS/ protokolok a Nyílt rendszerek összekapcsolása /OSI/ rétegelt referencia model fogalmaival kerültek meghatározásra. A 4.5 rész a P- és az R-csatornák adatkapcsolati rétegének funkcionális követelményeit határozza meg a Légijármű fedélzetén elhelyezett földi állomás /AES/ ésa Földi telepítésű földi állomás /GES/ közötti felhasználói adatok átvitele és jelátvitel céljából.

4.5.1.1 Minden AES és GES esetében az adatkapcsolati réteg kapcsolódó felületet kell, hogy képezzen az alábbiakhoz:

a) az alhálózati réteg;
b) az AES/GES vezérlés;
c) áramkör-üzemmódú szolgáltatások;
d) fizikai réteg.

4.5.1.2 Az adatkapcsolati szolgáltatás felhasználó meghatározásnak, amikor a 4.5 pontban meghatározott adatkapcsolati réteggel való összefüggésben használják, akkor a fenti felsorolás a), b) és c) tételeit kell tartalmaznia.

4.5.2 Adatkapcsolati réteg adat egység (LIDU)

4.5.2.1 Az adatkapcsolati réteg adat egységnek a teljes információs egységnek kell lennie, amit az adatkapcsolati szolgáltatás felhasználó és az adatkapcsolati réteg közötti interfészen keresztül továbbítanak egyetlen kölcsönhatással. Minden adatkapcsolati réteg adat egységnek tartalmaznia kell adatkapcsolati réteg vezérlő információt (LICI) és ha szükséges, egy adatkapcsolati szolgáltatás adat egység elemet /LSDU/.

4.5.2.2 Az adatkapcsolati réteg és az alhálózat réteg között kicserélt LIDU-nak tartalmaznia kell egy LSDU-t és LICI-t, kivéve, hogy az átviteli állapot jelző LIDU-nak (4-25. táblázat) - amelyet az adatkapcsolati réteg ad át az al-hálózati rétegnek - az adó végen csak LICI-t kell tartalmaznia. Az adatkapcsolati réteg és az AES/GES vezérlés között, valamint az adatkapcsolati réteg és az áramkör üzemmódú szolgáltatás között kicserélt LIDU csak LICI-t tartalmazzon.

4.5.2.3 ADATKAPCSOLATI RÉTEG VEZÉRLÉS INFORMÁCIÓ (LICI)

4.5.2.3.1 Az adatkapcsolati réteg és az a-lhálózati réteg között kicserélt LICI paramétereket a 4-11. táblázat szerint kell meghatározni.

4.5.2.3.2 Az adatkapcsolati réteg és az áramköri üzemmódú szolgálatok között kicserélt LICI paramétereket a 4-38. táblázat szerint kell meghatározni.

4.5.2.3.3 Az adatkapcsolati réteg és az AES, valamint GES vezérlési funkciók között kicserélt LICI paramétereket a 4.9.2.1.2 pont és a 4-45. táblázat szerint kell meghatározni.

4.5.2.4 AZ ADATKAPCSOLATI SZOLGÁLTATÁS ADAT EGYSÉG (LSDU)

Megjegyzés. – Az adatkapcsolati szolgáltatás adat egység (LSDU) a LIDU egy részét képezi, azt, amely azonosságát megőrzi az adatkapcsolat szolgáltatás két egymással kommunikáló felhasználója között.

4.5.2.4.1 Az adatkapcsolat szolgáltatási adat egységnek (LSDU) tartalmazni kell kapcsolat szolgáltatás felhasználói adatokat és azokat az al-hálózati rétegből érkező LIDU-ból kell kiemelni.

4.5.2.4.2 *AZ ADATKAPCSOLAT SZOLGÁLTATÁSI ADAT EGYSÉG FORMÁTUM*

Az LSDU formátumnak azonosnak kell lenni a 4.7 pontban meghatározott Műholdas al-hálózat-függő funkció /SSND/ alréteg műholdas al-hálózati protokol adat egységeivel (SNPDU).

4.5.3 Adatkapcsolati protokol adat egység (LPDU)

4.5.3.1 Az adatkapcsolati protokol adat egységeknek (LPDUs) a 4.5.3.2 pontban meghatározott jel egységeknek (SU) kell lenniük.

4.5.3.2 JEL EGYSÉG (SU)

4.5.3.2.1 A jel egységeknek a P- és az R-csatornák viszonylatában két hosszúságnak kell lennie:

a) 96 bit (12 oktett): szabvány hosszúságú jel egység a P-csatornára;

b) 152 bit (19 oktett): megnövelt hosszúságú jel egységek az R-csatornára.

4.5.3.2.2 Minden jel egységnek /SU/ tartalmaznia kell vezérlés információt és tartalmazhat a jel egység típusától függő felhasználói adatokat.

4.5.3.2.3 *LIDU LEKÉPEZÉSE – SU KÉSZLETBE*

4.5.3.2.3.1 Az adatkapcsolati réteg által vett minden LIDU-t, az egyszintű adatkapcsolati réteghez való továbbítás előtt, egy jel egység készletbe kell leképezni. Minden jel egységnek, vagy egy "magányos jel egységnek" (LSU) nevezett egyedi jel egységből, vagy több mint egy jel egységből kell állnia, amelyet első jel-egységének a "kezdő jel-egységnek (ISU)" és az azt követőknek a "soronkövetkező jel-egységeknek (SSUs)" kell lenniük.

4.5.3.2.3.2 *Az LSDU-ból és LICI-ből álló LIDU*

4.5.3.2.3.2.1 A P-csatorna esetén a 2, 3 vagy 4 oktett hosszúságú LSDU-t a 4. Fejezet 2. Függelékének A2-37., A2-39. és A2-40. ábrái szerint kell szabvány hosszúságú LSDU-ba leképezni. A 4 oktettnél nagyobb hosszúságú LSDU-nak egy ISU-ban kell végződnie, amit maximum 63 SSU követ. A négy oktettnél hosszabb LSDU első oktettjét egy ISU 2 oktettes felhasználói adatmezőbe kell leképezni (4. Fejezet 2. Függelék A2-37. ábra). A fennmaradó oktetteket a sorszámokkal ellátott (4. Fejezet 3. Függelék 59. Szakasz) soronkövetkező SSU-k 8 oktettes felhasználói adatmezeibe kell leképezni (4. Fejezet 2. Függelék A2-38. ábra). Az SSU-k száma az LSDU oktettjeinek számától függ. A SU készlet minden jel egységének vezérlési információját a LICI-ben található információból, valamint a belső adatkapcsolati réteg protokol folyamatai által generált információkból kell leképezni.

Megjegyzés. – Minden ISU tartalmaz olyan információt, ami az SU készlet utolsó SSU-jának felhasználói adatmezejében lévő oktettek számát jelzi.

4.5.3.2.3.2.2 Az R-csatornánál egy LSDU-nak maximálisan 3 kibővített hosszúságú SU-ba kell leképezést végeznie az SU készlet LSDU felhasználói adatmezejében lévő első 11 oktettet tartalmazó (4. Fejezet 2. Függelék A2-44. ábra) ISU-jával. A fennmaradó oktetteket az SSU-k 11 oktettes felhasználói adatmezeibe kell leképezni, a sorrend kijelölő mutató által szabályozott sorrendben (4. Fejezet 3. Függelék 58. tétel). Az SU készlet minden jel egységének vezérlő információját a LICI-ben található információból, valamint a belső adatkapcsolati réteg protokol folyamatai által generált információkból kell leképezni.

4.5.3.2.3.3 *A csak LICI-ből álló LIDU*

A csak LICI-ből álló LIDU esetében az SU készletet a LICI-ben található információ, valamint a belső adatkapcsolati réteg protokol folyamatai által a megfelelő SU vezérlő információ mezőibe generált információk leképezésével kell létrehozni.

4.5.3.2.4 *SU KÉSZLET – LIDU LEKÉPEZÉS*

4.5.3.2.4.1 A vételi oldalon az SU készletet LIDU-vá kell visszaalakítani a kapcsolat szolgáltatás felhasználójához való eljuttatása előtt.

4.5.3.2.4.2 Felhasználói adatokat tartalmazó SU(k) SU készlete esetében a keletkező LIDU-nak LSDU-t és LICI-t kell tartalmaznia. Az LSDU-t a vett teljes SU készlet minden SU-ja felhasználói adatmezőinek kombinálásával kell visszaállítani. A LICI-t az SU(k) ellenőrző információiból kell előállítani.

4.5.3.2.4.3 Felhasználói adatokat nem tartalmazó SU(k) SU készlete esetében a keletkező LIDU-nak csak LICI-t kell tartalmaznia. A LICI-t aZ SU-k vezérlő információiból kell előállítani.

4.5.3.3 JELEGYSÉG FORMÁTUM

4.5.3.3.1 A P- és R-csatornán továbbított összes SU formátumának meg kell felelnie a 4. Fejezet 2. Függelékében bemutatottaknak. A jel egység mező leképezése és a bitek továbbítása az A2-1. ábra szerint kell, hogy történjen. A jel egység mező kódolása és meghatározásai a 4. Fejezet 3. Függelékében meghatározottaknak megfelelőek kell ,hogy legyenek.

4.5.3.3.2 A vevő adatkapcsolati réteg által fel nem ismert SU-kat figyelmen kívül kell hagyni.

Megjegyzés. – A 4. Fejezet 2. Függelékében meg nem határozott SU-k az AMSS szolgáltató és AMSS felhasználó közötti kölcsönös megegyezés alapján biztonsági kérdéseket nem érintő szolgáltatások esetében felhasználhatók.

4.5.4 LIDU útválasztás

A vevő adatkapcsolati rétegnek a LICI-ben (akár a GES, akár az AES esetében), a közlemény típus paramétert kell használnia a LIDU megfelelő adatkapcsolati szolgáltatás felhasználóhoz való irányítása céljából. Az alsávi C- vagy R/P-csatornákon való továbbítás esetén a továbbító adatkapcsolati rétegnek (akár a GES, akár az AES esetében) az áramkör üzemmódú szolgáltatásoktól (4-38. táblázat) kapott LICI-ben alkalmazni kell az útvonali paramétert a SU készlet megfelelő LIDU-hoz való irányítás céljából.

4.5.5 Elsőbbség (Q szám)

Egy LIDU-ból generált SU készlet minden SU-ját a kapcsolati rétegnek egy sorrenddel (Q számmal) kell megjelölnie az elsőbbség paraméternek megfelelően, amelyet a LICI-ben a kapcsolat szolgáltatás felhasználója juttat el hozzá. Minden adatkapcsolati jelző jel egység részére ki kell jelölni a közlemény típusának megfelelő Q számot. A Q számnak a 0 (legalacsonyabb elsőbbség) és a 15 (legmagasabb elsőbbség) közötti tartományban kell elhelyezkednie.

4.5.6 A Közvetlen összeköttetési szolgáltatás /DLS/ és a Megbízható összeköttetési szolgáltatás /RLS/ szolgáltatások

4.5.6.1 Az adatkapcsolati réteg két különböző típusú szolgáltatást kell hogy nyújtson, közvetlen összeköttetési szolgáltatás (DLS) és megbízható összeköttetési szolgáltatás (RLS) néven.

4.5.6.2 A DLS-nek egy olyan adatkapcsolati réteg szolgáltatásnak kell lenni, amelyben a SU-kat bármelyik elvesztett SU azonosítása és újra-továbbítása nélkül kell az egyszintű adatkapcsolati réteghez továbbítani.

Megjegyzés. – DLS csak az AES/GES vezérlő funkciók és áramköri üzemmódú szolgáltatások részére áll rendelkezésre.

4.5.6.3 Az RLS-nek egy olyan adatkapcsolati réteg szolgáltatásnak kell lenni, amely biztosítja bármely elveszett SU(k) azonosítását és újra-továbbítását.

4.5.7 P-csatorna protokol

Megjegyzés. – Ebben a szakaszban az "AES" és "GES" kifejezések használata az AES-en és GES-en belüli P csatorna protokoll adatkapcsolati réteg funkcióira vonatkozik.

4.5.7.1 ÁLTALÁNOS

A P-csatorna adatkapcsolati réteg funkcióinak a 4.5.7.2 és 4.5.7.3 pontokban meghatározottaknak megfelelőnek kell lenni.

4.5.7.2 FÖLDI TELEPÍTÉSŰ FÖLDI ÁLLOMÁS (GES)

4.5.7.2.1 Egy LIDU vételekor a GES ki kell, hogy jelöljön részére egy rendelkezésre álló referencia számot (amely olyan, hogy pillanatnyilag ugyanazzal a Q számmal nincs egy LIDU-ra kijelölve) valahányszor, amikor ez a 4.5.7.2.2 pontnak megfelelően megvalósítható; ugyanakkor, a GES nem jelölhet ki referencia számot olyan LIDU-k részére, amelyek áramköri üzemmódú szolgáltatásoktól érkeztek és az olyan rendszertábla adási LIDU-k számára, amelyek a GES vezérlés felől érkeztek. Ha nem lehet referencia számot kijelölni egy LIDU számára, akkor a LIDU-t addig kell tárolni, amíg egy referencia számot a részére ki nem osztanak.

Megjegyzés. – Az áramkör üzemmódú LIDU-kat az áramköri üzemmódú szolgáltatások látják el alkalmazási referencia számokkal.

4.5.7.2.2 Bármely Q elsőbbségi szintnél egy egyedi AES-hez rendelt LIDU részére történő referencia szám minden egyes kijelölésének az összes, ehhez az AES-hez rendelt, ugyanazon a Q szinten lévő referencia szám nélküli LIDU közül a legrégebbihez kell történnie. A GES nem oszthat ki referencia számot egy RLS LIDU részére, ha már van egy másik LIDU részére ugyanazon Q számmal érvényesen kijelölt és ugyanazon AES-nek megcímzett referencia szám. A DLS LIDU kivételével, amit LSU-kba képeznek le, ugyanazon Q számmal rendelkező LIDU-k részére két egymást követő referencia szám nem jelölhető ki. Az RLS esetében a GES által kijelölt referencia szám nem lehet egyenlő az ugyanazon Q számmal rendelkező RLS-nek utoljára kiosztott, és ugyanazon AES-nek megcímzett referencia számmal.

4.5.7.2.3 A DLS esetében a referencia számot a kijelölése után azonnal fel kell szabadítani. Az RLS esetében a referencia számot azután kell felszabadítani, miután a GES egy átviteli állapotjelző LIDU-t küld (4-25. táblázat) a GES adatkapcsolati szolgáltatás felhasználója részére. A GES a 4.5.7.2.2 pontnak megfelelően nem jelölhet ki újra egy felszabadított referencia számot addig, amíg a felszabadítása előtt rendelkezésre álló összes referencia szám kijelölésre nem kerül. Ez alól az egyedüli kivétel az az eset lehet, amikor egy DLS LSU-ba leképezést végző LIDU számára referencia szám került kijelölésre, ami azonnal újra kijelölhető egy LSU-ba leképezést végző másik DLS LIDU részére.

4.5.7.2.4 A LIDU részére történő referencia szám kijelölését követően vagy az áramkör üzemmódú LIDU vételekor a 4.5.3.2.3 pontnak megfelelően egy SU készletet kell létrehozni. A legrégebben továbbításra váró SU-k közül mindig a legnagyobb számmal rendelkezőt kell először továbbítani. Egy SU készlet ISU-ját vagy adás-ismétlő RTX SU-ját kell az SSU-kat megelőzően továbbítani és az SSU-k továbbítását a csökkenő besorolási számaik szerint kell elvégezni (4. Fejezet 3. Függeléke 59. tétel). A teljes SU készlet továbbítását követően a GES-nek a következőket kell elvégeznie:

4.5.7.2.4.1 A Megbízható összeköttetési szolgáltatás /RLS/ esetében:

a) Ha egy olyan P-csatorna nyugtázó (PACK) SU (4. Fejezet 2. Függeléke, A2-49. ábra) érkezik az AES-től, amely nem jelez hibát az SU készletben, akkor a GES-nek sikeres átvitelt jelző (4-25. táblázat) átviteli állapotjelző LIDU-t kell küldenie a GES kapcsolati szolgáltatás felhasználója részére.

b) Ha az AES-től egy olyan P-csatorna nyugtázó SU érkezik, amely az SU készleten belül hiányzó SU-kat jelez és a PACK SU készletből nem érkezik egy másik PACK SU tG2 másodpercen belül (4. Fejezet 4. Függeléke) azon időponttól számítva, hogy a PACK SU készlet utolsó PACK SU-ja megérkezett, vagy ha nem várható, hogy több hiányzó SU-t azonosító PACK SU érkezik, akkor a GES-nek egy adás-ismétlő SU készletet kell továbbítania. Az adás-ismétlő SU-nak egy adás-ismétlő fej-rész (RTX) SU-t (4. Fejezet 2. Függelék A2-41. ábra) kell tartalmaznia, amit a PACK SU készlet vett PACK SU-jaiban azonosított, hiányzó SU-k követnek. Ezt követően a GES-nek a 4.5.7.2.4.1 pont szerint kell eljárnia, azonban, ha az AES-től az SU készletből hiányzó SU-kat jelző PACK SU készlet érkezik, mielőtt a teljes adás-ismétlő SU készlet továbbításra kerül, akkor a GES-nek figyelmen kívül kell hagynia a vett PACK SU-t.

c) Ha az SU készlet teljes adás-ismétlését kérő PACK SU (4. Fejezet, 2. Függeléke, A2-49. ábra) érkezik az AES-től, akkor a GES-nek egy ISU és SSU-k sorozataként a teljes SU készletet újra kell továbbítania. Ezt követően a GES-nek a 4.5.7.2.4.1 pont szerint kell eljárnia.

d) Ha az AES-től nem érkezett az SU készlethez társított PACK SU tG1 másodpercen belül (4. Fejezet 4. Függeléke) azon időponttól számítva, hogy az SU készlet utolsó SSU-ja (eredeti vagy adás-ismétlő) továbbításra került, akkor a GEs-nek egy Nyugtázást kérő (RQA) SU-t (4. Fejezet 2. Függeléke A2-27. ábra) kell továbbítania az AES felé. A GES-nek az RQA SU-t minden tG1 másodpercben továbbítania kell az utolsó RQA SU elküldését követően, amíg válasz nem érkezik az AES-től, vagy a továbbított RQA SU-k száma egyenlő lesz öttel. Ha az RQA SU ötödik elküldését követően eltelik tG1 másodperc anélkül, hogy az AES felől megérkezne a megfelelő PACK SU, akkor a GES-nek hibajelző átviteli állapotjelzőt (4-25. táblázat) kell küldenie a GES adatkapcsolati szolgáltatás felhasználójához, és meg kell szüűtetnie az SU készlet feldolgozását; egyéb esetekben a GES-nek a 4.5.7.2.4.1 pont szerint kell eljárnia.

4.5.7.2.4.2 Ha az AES felől olyan SU készletet azonosító PACK SU érkezik, amely nincs jelen a GES-ben, akkor a vett PACK SU-t figyelmen kívül kell hagyni.

4.5.7.2.5 Ha nincsenek továbbításra váró SU-k (adat vagy jelző), akkor a GES-nek egy AES rendszertábla adási SU-t (4. Fejezet 2. Függeléke A2-30.-tól az A2-34.-ig terjedő ábrák) kell továbbítania, amennyiben a GES vezérlés felől érkezett LIDU-ból ilyet előállítottak; egyéb esetekben a GES-nek egy kitöltő SU-t (4. Fejezet 2. Függeléke, A2-42. ábra) kell kibocsátania.

4.5.7.3 LÉGIJÁRMŰ FEDÉLZETÉN ELHELYEZETT FÖLDI ÁLLOMÁS (AES)

4.5.7.3.1 Egy LSU-ból álló SU készlet vételekor az AES-nek a 4.5.3.2.4 pont szerint egy LIDU-t kell létrehoznia és az AES adatkapcsolati szolgáltatás megfelelő felhasználójához eljuttatnia. Ezt követően RLS-t felhasználó LSU esetén az AES-nek hibamentességet jelző PACK SU-t kell küldenie a GES-nek. Az AES-nek utasítást kell adnia egy R-csatorna frekvencia kiválasztására, és ezt követően újra el kell küldenie ezt a PACK SU-t, amennyiben az SU készletet azonosító RQA SU-t vesznek egy ugyanezzel a Q számmal rendelkező másik SU készlet előtt.

4.5.7.3.2 Egy SU készletből álló SU-k vételekor az AES-nek a vett SU-kat egy SU készletbe kell újra-társítania referencia számaik, Q számaik és sorozat számaik alapján (4. Fejezet 3. Függeléke 43., 46.

és 59.) Az ilyen SU készlet esetében, ha egy SSU érkezik a megfelelő ISU nélkül, vagy előtte RTX SU érkezett, akkor az AES-nek figyelmen kívül kell hagynia az az SSU-t.

4.5.7.3.3 Többszörös SU-kból álló SU készlet esetén egy ISU vételét követően az AES-nek meg kell határoznia, hogy a GES felől várhatók-e az ISU által fejrészezett SU készletnek megfelelő további SSU-k a következő feltételnek megfelelően:

Nem várhatók az SU készletnek megfelelő SSU-k, a akár az SU készlet utolsó SSU-ja, vagy a befejezésre váró SU-nál kisebb Q számmal ellátott SU, vagy a befejezésre váró SU-val azonos Q számú, de más referencia számú, vagy egy AES rendszertábla adási SU, vagy kitöltő SU kerül vételre.

Megjegyzés. – Ezen feltételek alkalmazásához az AES az összes vett SU-t, az AES ID-jüktől függetlenül, figyelembe veszi.

4.5.7.3.3.1 Amikor egy azonos Q számú és AES ID-jű, de különböző referencia számú befejezésre váró SU készlet érkezik a GES felől, az AES-nek figyelmen kívül kell hagynia a befejezésre váró nem teljes SU készletet.

4.5.7.3.3.2 Az AES-nek figyelmen kívül kell hagynia a vett SU készletet (befejezett vagy nem befejezett), ha annak a Q száma és referencia száma megegyezik az utoljára befejezett és egy LIDU-ba azonos Q szám alatt újra összeállított SU készletével.

4.5.7.3.4 Ha nem számítanak az SU készletnek megfelelő további SU-kra, akkor az AES-nek meg kell határoznia, hogy vannak-e hiányzó SU-k a vett SU készletben. Ezt követően az AES-nek a következőket kell tennie:

4.5.7.3.4.1 Közvetlen összeköttetési szolgáltatás /DLS/ esetében:

a) Ha nincsenek hiányzó SU-k, akkor az AES-nek a 4.5.3.2.4 pont szerint újra össze kell állítania az SU-kat egy LIDU-ba és azt továbbítania kell az AES adatkapcsolati szolgáltatás megfelelő felhasználója felé.

b) Ha vannak hiányzó SU-k, akkor az AES-nek figyelmen kívül kell hagynia a nem teljes SU készletet.

4.5.7.3.4.2 Megbízható összeköttetési szolgáltatás /RLS/ esetében:

a) Ha nincsenek az SU készletben hiányzó SU-k, akkor az AES-nek a 4.5.3.2.4 alrész szerint az SU készletet egy LIDU-ba kell újra összeállítania és azt továbbítania kell az adatkapcsolati szolgáltatás megfelelő felhasználójához. Ezt követően az AES-nek egy hibamentességet jelző PACK SU-t kell küldenie a GES-nek. Ha ezt követően ugyanazon SU készlet részére egy nyugtázást kérő RQA SU érkezik, akkor az AES-nek egy R-csatorna frekvencia kiválasztására kell utasítást adni, és azt követően újra továbbítani kell a PACK SU-t.

b) Ha a hiányzó SU-k száma kevesebb mint 43, akkor az AES-nek egy vagy több, a PACK SU készletet alkotó PACK SU-t kell küldenie a GES részére, azonosítva a hiányzó SU-kat és kérve azok adás-ismétlését.

Megjegyzés. – Egy hibajelző PACK SU három hiányzó SU-t azonosíthat.

c) Ha egy SU készletből több mint 42 SU hiányzik, akkor az AES-nek egy PACK SU-ból álló, a teljes SU készlet adás-ismétlését kérő PACK SU készletet kell elküldenie a GES részére.

4.5.7.3.4.2.1 Egy részleges vagy teljes adás-ismétlést kérő PACK SU-nak a GES részére történő elküldését követően az AES-nek a következőket kell elvégeznie:

a) Ha egy RQA SU érkezik a GES-től tA1 másodperccel (4. Fejezet 4. Függeléke) azon időpont után, hogy a PACK SU-t a GES-hez továbbították, akkor az AES-nek utasítást kell adnia egy R-csatorna frekvencia kiválasztására és azt követően az utolsó PACK SU készletet újra továbbítania kell a GES részére, valamint a
4.5.7.3.4.2.1 pont szerint kell eljárnia. Amennyiben a teljes PACK SU készlet továbbítása előtt egy RQA SU érkezik a GES-től, akkor az AES-nek az RQA SU-t figyelmen kívül kell hagynia.

b) Egy RTX SU által fejlécelt SU-k vagy GES-től érkező ISU vételekor az AES-nek meg kell határoznia, hogy várhatók-e a 4.5.7.3.3 pontban meghatározott feltételeket kielégítő, az újra-továbbított SU készletnek megfelelő további SU-k. Ezt követően az AES-nek meg kell határoznia, hogy az RTX SU-ban azonosított hiányos SU készlet jelen van-e vagy nincs jelen az AES-ben. Ha a hiányos SU készlet nincs jelen az AES-ben, akkor az AES-nek figyelmen kívül kell hagynia az RTX SU által fejrészezett vett SU készletet, a másik esetben az AES-nek az RTX SU által fejlrészezett, vett SU-kat be kell illesztenie a hiányos SU készletbe. A vett, újra-továbbított SU-k hiányos SU készletbe történő beillesztése és a duplikált SU-k (szükség szerint) figyelmen kívül hagyása után az AES-nek meg kell határoznia, hogy a keletkezett SU készlet teljes-e, vagy nem. Ezt követően az AES-nek a következőket kell elvégeznie:

1) Ha az SU készlet teljes, akkor az AES-nek egy hibátlanság jelző PACK SU-t kell küldenie a GES részére. Ezt követően az AES-nek a teljes SU készletet a 4.5.3.2.4 pont szerint újra össze kell egy LIDU-ba állítania, és azt el kell küldenie az AES adatkapcsolati szolgáltatás megfelelő felhasználójához. Ha ezt követően ugyanazon SU készlet részére egy nyugtázást kérő RQA SU érkezik ezen AES egy azonos Q számú másik SU készlete előtt, akkor az AES-nek utasítást kell adnia egy R-csatorna frekvencia kiválasztására és azt követően újra továbbítania kell a PACK SU-t.

2) Ha az SU készlet nem teljes, akkor az AES-nek a 4.5.7.3.4.2 b) és c) pontjaival összhangban egy PACK SU készletet alkotó egy vagy több PACK SU-t kell továbbítania a GES részére. Ezt követően az AES-nek a
4.5.7.3.4.2.1 pont szerint kell eljárnia.

c) Ha a GES-től az újra-továbbítást igénylő teljes PACK SU elküldését követő tA1 másodpercen belül (4. Fejezet 4. Függeléke) nem érkezik válasz, akkor az AES-nek utasítást kell adnia egy R-csatorna frekvencia kiválasztására, és azt követően a PACK SU készletet a hiányzó SU-k azonosításával ismét el kell küldenie a GES-hez. Az AES-nek a PACK SU-t minden tA1 másodpercben (4. Fejezet 4. Függeléke) újra továbbítania kell az utolsó elküldött PACK SU időpontját követően, addig, amíg a GES-től egy megfelelő újra-továbbított SU készlet érkezik, vagy amíg az ugyanazon hiányzó SU-kat azonosító PACK SU készlet továbbításának száma egyenlő lesz öttel. Ha a PACK SU készlet ötödik újra-küldése után eltelik a tA1 másodperc az újra-továbbított SU-k GES-től való vétele nélkül, akkor az AES-nek figyelmen kívül kell hagynia a befejezetlen SU készletet.

4.5.7.3.5 A GES-től érkező nyugtázási (RQA) SU kérésre az AES-nek egy a teljes PACK SU készlet újra-továbbítását kérő PACK SU küldésével kell válaszolnia, ha az RQA SU olyan SU készletet azonosít, amely nem érkezett az AES-hez.

4.5.7.3.6 Az AES adatkapcsolati rétegnek a rendszertábla adás-javító számát továbbítania kell az AES vezérléshez a műhold/sugár-azonosító P_{smc}-csatornán vett rendszertábla adási sorozat első SU-jának vételekor. Egy teljes vagy részleges adás-sorozat szériának megfelelő adás LIDU-t (lásd 4. 10.4.5.2.2) kell összeállítani és az AES vezérléshez eljuttatni, miután a széria összes várható SU-jai megérkeztek, vagy miután egy másik, a befejezésre váró szériával egyenlő vagy annál nagyobb revízió számú sorozat egy SU-ja megérkezik.

4.5.8 R-csatorna protokol

Megjegyzés. – A 4.5.8 pontban használt “AES” és GES” kifejezések az AES-en és a GES-en belüli R-csatorna protokol adatkapcsolati réteg funkcióira vonatkoznak.

4.5.8.1 ÁLTALÁNOS

4.5.8.1.1 Az R-csatorna protokollal kapcsolatos adatkapcsolati réteg funkcióknak meg kell felelniük a 4.5.8.2 és a 4.5.8.3 pontokban meghatározottaknak.

4.5.8.2 LÉGIJÁRMŰ FEDÉLZETÉN ELHELYEZETT FÖLDI ÁLLOMÁS (AES)

4.5.8.2.1 Az RLS LIDU-jának vételekor az AES-nek egy referencia számot (4. Fejezet ,3. Függeléke 46. tétel) kell kijelölnie számára, ha nincs érvényes referencia szám kijelölve az RLS egy olyan LIDU-jának, amelynek "Q" száma megegyezik a vett LIDU "Q" számmal. A DLS LIDU-jának vételekor az AES-nek ki kell jelölnie egy rendelkezésre álló (azonos Q számmal rendelkező LIDU-nak jelenleg ki nem osztott) referencia számot a részére, azonban az AES nem jelölhet ki referencia számot az áramköri üzemmódú szolgálatoktól érkezett LIDU-k részére. Ha egy LIDU-nak nem jelölnek ki referencia számot, akkor a LIDU-t addig kell tárolni, amíg számára egy referencia szám kijelölésre kerül. A referencia számok minden egyes kijelölését a referencia számok nélküli legrégebben vett LIDU-k részére kell elvégezni. Az egyforma Q számmal rendelkező LIDU-k azonos referencia számokkal való két egymást követő kijelölése nem történhet meg, azon két LIDU kivételével, amelyek DLS LSU-ba kerültek leképezésre.

Megjegyzés. – Áramkor üzemmódú szolgáltatás LIDU-i az áramkör üzemmódú szolgáltatás által vannak kijelölve alkalmazási referencia számokhoz.

4.5.8.2.2 A DLS esetében a referencia számot rögtön a kijelölését követően fel kell szabadítani. Az RLS esetében a referencia számot azután kell felszabadítani, hogy az AES egy átviteli állapotjelző LIDU-t (4-25. táblázat) küld az AES adatkapcsolati felhasználójának. Az AES nem oszthat ki újra egy felszabadított referencia számot addig, amíg a felszabadítása előtt rendelkezésre álló összes referencia szám kijelölésre nem kerül. Ez alól az egyedüli kivétel az a referencia szám, amely egy LSU-ba leképezett DLS LIDU részére került kijelölésre, s ami azonnal újra kijelölhető egy LSU-ba leképezett másik DLS LIDU számára.

4.5.8.2.3 Egy LIDU részére történt referencia szám kijelölését követően vagy egy áramkör üzemmódú szolgálatoktól érkező LIDU vételekor a 4.5.3.2.3 pontnak megfelelően egy SU készletet kell létrehozni. Az átvitelre váró összes SU közül a legnagyobb Q számmal rendelkező legrégebbi SU-kat kell minden esetben először továbbítani. Egy SU készlet SU-jait kijelölő számaik emelkedő sorrendje alapján kell továbbítani (4. Fejezet 3. Függeléke 58. tétel).

4.5.8.2.4 *RLS esetében.* Minden átvitelre kerülő SU készlet esetében az AES-nek a következőket kell végrehajtani:

a) Válaszolnia kell a rendeltetési GES-től érkező R-csatorna nyugtázási (RACK) SU-kra a következők szerint:

1) Ha a RACK SU (4. Fejezet 2. Függeléke A2-28. ábra) azt jelzi, hogy a GES-nél az SU készletet teljes egészében vették, akkor az AES-nek egy, a sikeres átvitelt jelző átviteli állapotjelző LIDU-t (4-25. táblázat) kell küldenie az AES adatkapcsolati szolgáltatás felhasználója számára.

2) Ha a RACK SU (4. Fejezet 2. Függeléke A2-29. ábra) egy vagy több olyan SU-t azonosít, amely(ek)et még nem vett, akkor az AES-nek utasítást kell adnia egy R-csatorna frekvencia kiválasztására, és a hiányzó SU-kat a kijelölő számaik emelkedő sorrendje alapján újra-továbbítania kell. Bármely egyéb, hiányzó SU-kat azonosító RACK SU vételekor az AES-nek figyelmen kívül kell hagynia azt, ha az előzőleg vett RACK SU által azonosított összes hiányzó SU átvitele még nem fejeződött be. Ugyanakkor, akár ha:

i) az első RACK SU-n kívül még öt másik, hiányzó SU-kat azonosító RACK SU érkezik, mielőtt az AES teljes egészében továbbítja az első RACK SU-ban azonosított bármely hiányzó SU-t, vagy

ii) az első RACK SU két hiányzó SU-t azonosított, és az egyik továbbításra került, és a továbbítást követően öt újabb, hiányzó SU-t azonosító RACK SU érkezik egy másik SU továbbítása nélkül, akkor az AES-nek egy hibás átvitelt jelző átviteli állapotjelző LIDU-t (4-25. táblázat) kell továbbítania az AES adatkapcsolati felhasználója részére, és meg kell szüntetnie azon SU készlet feldolgozását.

Megjegyzés. – Az AES-nél vett RACK SU egy SU készlet legfeljebb két hiányzó SU-ját azonosíthatja.

b) Ha egy RACK SU a rendeltetési GES-től nem érkezik meg tA3 másodpercen belül (4. Fejezet 4. Függeléke) azon időponttól számítva, hogy egy készlet utolsó SU-ja (az eredeti SU készlet vagy az eredeti SU készletnek megfelelő továbbított SU készlet) továbbításra kerül, akkor az AES-nek utasítást kell adnia egy R-csatorna frekvencia kiválasztására a rendelkezésre álló R-csatorna frekvenciák csoportjából és újra továbbítania kell az SU készletet. Az AES-nek ezt az eljárást addig kell ismételnie, amíg a GES-től egy nyugtázás érkezik, azzal a kivétellel, hogy ugyanazon SU készlet újra-továbbításának a száma nem haladhatja meg az ötöt. Ha egy RACK SU az ötödik ismétlést követően tA3 másodpercen belül nem érkezik meg, akkor az AES-nek egy hibás átvitelt jelző átviteli állapotjelző LIDU-t (4-25. táblázat) kell továbbítania az AES adatkapcsolati felhasználója részére és meg kell szüntetnie az SU készletnek a feldolgozását.

4.5.8.3 FÖLDI TELEPÍTÉSŰ FÖLDI ÁLLOMÁS (GES)

4.5.8.3.1 A bejelentkezett AES-től érkező SU-kat a GES-nek az AES ID-jének, Q számának, referencia számának és sorozat kijelölőjének (4. Fejezet, 3.Függeléke 58. tétel) megfelelően kell rendeznie.

4.5.8.3.2 *A Megbízható összeköttetési szolgáltatás /RLS/ esetében*

4.5.8.3.2.1 Azután, hogy egy SU készlet SU-ját a készlet befejezése nélkül veszi a GES, akkor a GES-nek a fennmaradó hiányzó SU-kat azonosító RACK SU-t kell küldenie az AES részére, ha az alábbiak bármelyike igaz:

a) ha a vett SU az SU készlet utolsó SU-ja, vagy az SU készlet hiányzó SU-jainak utolsó SU-ja;

b) ha tG4 másodperc hosszúságú időperiódus (4. Fejezet 4. Függeléke) eltelik anélkül, hogy egy másik SU (DLS vagy RLS) érkezne ugyanazon AES-től; vagy

c) ha a GES ugyanazon AES-től egymást követően vesz egy kisebb Q számú SU-t, vagy egy azonos Q számú, de eltérő referencia számú, DLS-t jelző SU-t.

Ha a hiányzó SU-kat azonosító RACK SU elküldése után a GES nem vesz tG3 másodpercen belül válasz SU-kat, akkor az AES részére újra kell továbbítania a RACK SU-t azon kivétellel, hogy a RACK SU elküldése helyett az SU készletet figyelmen kívül kell hagynia, ha összességében hat azonos RACK SU kerülhet elküldésre és az utolsó RACK SU átvitele óta eltelt tG3 másodpercen belül nem érkezett hiányzó SU. A GES-nek ugyancsak figyelmen kívül kell hagynia egy befejezetlen SU készletet, ha a készlet SU-jaival azonos Q számú, de eltérő referencia számú, RLS-t jelző SU érkezik ugyanazon AES-től.

4.5.8.3.2.2 Amikor egy teljes SU készletet vesz, a GES-nek a 4.5.3.2.4 pont szerint LIDU-t kell újra összeállítania, el kell küldenie az adatkapcsolati szolgáltatás megfelelő felhasználójához, és az AES részére egy hibamentességet jelző RACK SU-t kell küldenie.

4.5.8.3.2.3 Egy LIDU kialakítása után a GES-nek figyelmen kívül kell hagynia az ugyanazon AES-től egymást követően vett azonos Q számú és referencia számú összes SU készletet, amíg legalább egy azonos Q számú és eltérő referencia számú SU érkezik ugyanazon AES-től, valamint minden egyes figyelmen kívül hagyott SU készlet esetében egy hibamentességet jelző RACK SU-t kell újra-küldenie az AES felé.

4.5.8.3.2.4 Amikor két vagy több azonos Q számú és referencia számú, valamint sorozat jelölő SU érkezik ugyanazon AES-től a megfelelő LIDU kialakítása előtt, akkor egy kivételével az összeset figyelmen kívül kell hagyni.

4.5.8.3.3 *A Közvetlen összeköttetésiszolgáltatás /DLS/ esetében*

Miután egy SU készlet egy SU-ját a készlet befejezése nélkül veszi a GES, akkor a GES-nek figyelmen kívül kell hagynia a vett SU-kat, ha az alábbiak közül bármelyik igaz:
a) ha a vett SU az SU készlet utolsó SU-ja;
b) ha tG4 másodperc hosszúságú időperiódus (4. Fejezet 4. Függeléke) eltelik anélkül, hogy egy másik SU (DLS vagy RLS) érkezne ugyanazon AES-től; vagy
c) ha a GES ugyanazon AES-től egymást követően vesz egy kisebb Q számú SU-t, vagy egy azonos Q számú, de eltérő referencia számú SU-t.

Ha és amikor az SU készlet teljessé válik, akkor a GES-nek a 4.5.3.2.4 pont szerint egy LIDU-ba kell újra összeállítania azt és továbbítania kell az adatkapcsolati szolgáltatás megfelelő felhasználójához. Azonban, ha a teljes SU készlet SU-i egy különböző GES ID-t határoznak meg, és az SU készlet megfelel egy áramkör üzemmódú szolgáltatási LIDU-nak, akkor a GES-nek az SU készletet annak a GES-nek kell elküldenie, amelynek az ID-je meg van határozva.

4.6 ADATKAPCSOLATI RÉTEG T-CSATORNA ÉS ALSÁV C-CSATORNA PROTOKOLOK

4.6.1 Általános

4.6.1.1 A T-csatorna és alsávi C-csatorna adatkapcsolati rétegének felhasználói adat és jelzés átviteli funkcióinak meg kell felelni ük az ezen részben meghatározottaknak.

4.6.1.2 A 4.5 pontban meghatározott P- és R-csatornákat a T- és az alsávi C-csatornák beállítására kell felhasználni a 4.6.5 és 4.6.6 pontokban ismertettek szerint.

4.6.2 Adatkapcsolati réteg adat-egység (LIDU)

4.6.2.1 Az adatkapcsolati réteg és az al-hálózati réteg között a T-csatornán való továbbítással kicserélt LIDU-nak tartalmaznia kell az adatkapcsolati réteg vezérlést (LICI) és az adatkapcsolati szolgáltatási adat-egységet (LSDU), azzal a kivétellel, hogy az adatkapcsolati réteg által az al-hálózati réteghez az átviteli végnél továbbított adatátviteli állapotjelző LIDU-nak (4-25. táblázat) csak LICI-t kell tartalmaznia.

4.6.2.2 Az adatkapcsolati réteg és az áramkör üzemmódú szolgáltatások, valamint az adatkapcsolati réteg és AES/GES vezérlési funkciók között az alsávi C-csatornán való továbbításra kicserélt LIDU-nak csak LICI-t kell tartalmaznia.

4.6.2.3 ADATKAPCSOLATI RÉTEG VEZÉRLÉS (LICI)

4.6.2.3.1 Az adatkapcsolati réteg és az al-hálózati réteg között kicserélt LICI paramétereknek a 4-25. táblázatban meghatározottak szerintinek kell lenniük.

4.6.2.3.2 Az adatkapcsolati réteg és az áramkör üzemmódú szolgáltatások között kicserélt LICI paramétereknek a 4-38. táblázatban meghatározottak szerintinek kell lenniük. Az adatkapcsolati réteg és az al-hálózati vezérlési funkciók között kicserélt LICI paramétereknek a 4-44. és a 4-45. táblázatokban meghatározottak szerintinek kell lenniük.

4.6.2.4 ADATKAPCSOLATI SZOLGÁLTATÁSI ADAT-EGYSÉG (LSDU)

Az adatkapcsolati szolgáltatási adat-egységnek (LSDU) adatkapcsolati szolgáltatási felhasználói adatokat kell tartalmaznia és az al-hálózati rétegből érkező LIDU-ból kell kivonatolni.

4.6.3 Jel egység (SU)

4.6.3.1 A T-csatorna esetében két hosszúságú, az alsávi C-csatorna esetében egy hosszúságú SU-knak kell lenni:

a) 48 bit (6 oktett): impulzus-köteg azonosító egyenkénti jel egység (LSU) (4. Fejezet 2. Függeléke A2-43. ábra) a T-csatorna esetében.

b) 96 bit (12 oktett): szabvány hosszúságú SU-k a T- és az alsávi C-csatorna esetében.

4.6.3.2 A műholdas al-hálózati rétegből vett LIDU-nak megfelelő SU készlet minden SU-jának tartalmaznia kell a szabályozási és a felhasználói adatokat. Az áramkör üzemmódú szolgálatoktól és AES/GES vezérléstől érkezett LIDU-nak megfelelő SU készlet SU-jainak csak szabályozási információt kell tartalmaznia.

4.6.3.3 LIDU LEKÉPEZÉSE SU KÉSZLETBE

4.6.3.3.1 *LSDU-BÓL ÉS LICI-BŐL ÁLLÓ LIDU ESETÉBEN*

Egy LIDU-t egy SU készletbe kell leképezni. Minden SU készletnek egy “kezdő jel egységből” (ISU) kell állnia, amelyet maximum 63 “soronkövetkező jel egység” (SSU) követ. Az LSDU első két oktettjét az ISU két oktettes felhasználói adatmezejébe kell leképezni (4. Fejezet 2. Függeléke A2-37. ábra). A fennmaradó oktetteket a sorozat számok által szabályozott SSU-k 8-oktettes felhasználói adatmezeibe kell leképezni (4.Fejezet 3. Függelék 59. tétel). Az SSU-k számát az LSDU-ban lévő oktettek száma határozza meg. Az SU készlet minden egyes SU-jában lévő szabályozási információt a LICI-ben tartalmazott és a belső adatkapcsolati réteg protokol folyamatai által előállított információkból kell leképezni.

4.6.3.3.2 *LICI-BŐL ÁLLÓ LIDU ESETÉBEN*

A csak LICI-t tartalmazó LIDU esetében az SU készletet a LICI-ben található és a belső adatkapcsolati réteg folyamatai által előállított információknak a megfelelő SU szabályozó információs adatmezőibe való leképezésével kell előállítani.

4.6.3.4 SU KÉSZLET LEKÉPEZÉSE LIDU-BA

4.6.3.4.1 Egy SU készletet egy LIDU-ba kell leképezni, mielőtt továbbításra kerül az adatkapcsolati réteg felhasználója felé.

4.6.3.4.2 Egy felhasználói adatokat tartalmazó SU-(k)ból álló SU készlet esetében a keletkező LIDU-nak LSDU-t és LICI-t kell tartalmaznia. A keletkező LIDU LSDU-ját a vett teljes SU készlet egyes SU-jai felhasználói adatmezőinek egyesítésével kell újra összeállítani. A hozzárendelt LICI-t az SU-k vezérlő információiból kell előállítani.

4.6.3.4.3 Felhasználói adatokat nem tartalmazó SU-kból álló SU készlet esetében a keletkező LIDU-nak csak LICI-t kell tartalmaznia. A LICI-t a vett SU-k vezérlő információiból kell előállítani.

4.6.3.5 JEL EGYSÉG FORMÁTUM

4.6.3.5.1 A T-csatornán és az alsávi C-csatornán továbbított összes SU formátumának meg kell felelni a 4. Fejezet 4. Függelékében ábrázoltaknak. Az impulzus egység mező-leképezésének és a bitek továbbítási sorrendjének meg kell felelni az A2-1. ábrán bemutatottaknak. A jel egység mező kódolásának és meghatározásainak meg kell felelni a 4. Fejezet 3. Függelékében meghatározottaknak.

4.6.3.5.2 A vevő adatkapcsolati réteg által fel nem ismert SU-kat figyelmen kívül kell hagyni.

Megjegyzés. – A 4. Fejezet 2. Függelékében meg nem határozott SU-k egy AMSS szolgáltatás biztosítója és felhasználója közötti kölcsönös megállapodás szerint alkalmazhatók biztonságot nem érintő szolgálatok esetében.

4.6.4 T-csatorna átviteli protokol

Megjegyzés. – A 4.6.4 pontban használt "AES" és "GES" kifejezések az AES-en és a GES-en belüli T-csatorna átviteli protokol adatkapcsolati réteg funkcióira vonatkoznak.

4.6.4.1 ÁLTALÁNOS

A T-csatorna átviteli protokolok esetében az adatkapcsolati réteg funkcióknak meg kell felelni a 4.6.4.2 és a 4.6.4.3 pontokban meghatározottaknak.

4.6.4.2 LÉGIJÁRMŰ FEDÉLZETÉN ELHELYEZETT FÖLDI ÁLLOMÁS (AES)

4.6.4.2.1 Egy LIDU vételekor az AES-nek a 4.6.3.3.1 pont szerint egy SU készletet kell előállítania.

Megjegyzés. – A LIDU-k a T-csatorna foglalási protokolja által kijelölt referencia számúak.

4.6.4.2.2 *SU átvitel.* A T-csatornán az SU-kat kötegelt adatátviteli foglalásokban kell továbbítani. Az átvitelre váró összes SU közül a legnagyobb Q számmal rendelkező SU-k legrégebbi SU-ját kell elsőként továbbítani. Egy SU készlet ISU-ját vagy Adás-ismétlő /RTX/ SU-ját kell az SSU-k előtt továbbítani, és az SSU-kat csökkenő sorszámaik alapján kell továbbítani (4. Fejezet 3. Függeléke 59. tétel). Minden egyes bekezdő jelszakasz kezdetekor (a 4.4.4.3.4 pontban meghatározottak szerint) egy bekezdő jelszakasz azonosító SU-t (4. fejezet 2. függeléke A2-43. ábra) kell továbbítani. Amikor egy bekezdő jelszakasz átvitele közben nem áll SU továbbításhoz rendelkezésre, akkor egy kitöltő SU-t (4. Fejezet 2. Függeléke A2-42. ábra) kell továbbítani. Ugyanakkor, amennyiben a kötegelt foglalásos adatátvitel kezdetekor nem állnak SU-k a rendelkezésre, akkor az AES-nek meg kell akadályoznia a megfelelő kötegelt adatátviteli impulzusok továbbítását.

4.6.4.2.3 *Az RLS esetében.* Minden egyes továbbított SU készlet esetében az AES-nek a következőket kell végrehajtania:

a) válaszolnia kell minden T-csatorna nyugtázási közleményre (TACK), amelyet a rendeltetési GES küld válaszként az SU készletnek a P-csatornán keresztül, a következők szerint:

1) Amikor a TACK SU (4. Fejezet 2. Függelék A2-29. ábra) azt jelzi, hogy a GES-nél az SU készlet teljes egészében megérkezett, akkor az AES-nek egy sikeres átvitelt jelző (4-25. táblázat) átviteli állapotjelző LIDU-t kell küldenie az adatkapcsolati szolgáltatás felhasználójának;

2) Amikor a TACK SU (4. fejezet 2. függeléke A2-29. ábra) azt jelzi, hogy a teljes U készlet elveszett, akkor az AES-nek a teljes eredeti SU készletet újra ki kell bocsátania;

3) Amikor a TACK SU (4. Fejezet 2. Függeléke A2-29. ábra) elveszett SU-kat jelez a GES-nél, ha nem várható ugyanazon SU készlet újabb hiányzó SU-it jelző újabb TACK SU, vagy ha egy vagy több TACK SU várható, de egy sem érkezik az előző TACK SU vételétől számított tA5 másodpercen belül (4. Fejezet 4. Függeléke), akkor az AES-nek újra-továbbítania kell a vett TACK-SU-kban jelzett SU-kat. Bármely továbbított SU előtt egy adás-ismétlő fejrész (RTX) SU-t (4. Fejezet 2. Függeléke A2-41. ábra) kell továbbítani. Ezt követően, ha ugyanazon SU készlethez rendelt hiányzó SU-kat jelző bármely további TACK SU érkezik, mielőtt a teljes adás-ismétlő SU készlet továbbításra kerül, akkor az AES-nek figyelmen kívül kell hagynia a vett TACK SU-t.

Azonban az AES nem továbbíthatja ugyanazon készletet, akár az eredeti, akár az adás-ismétlő SU készletet, háromnál több alkalommal. Amennyiben a harmadik átvitel után az AES olyan TACK SU-t vesz, ami ugyanazon SU készlet negyedik továbbítását eredményezné, akkor az AES-nek egy hibát jelző átviteli állapotjelző LIDU-t kell küldenie az adatkapcsolati szolgáltatás felhasználójának, és meg kell szüntetnie az SU készlet feldolgozását.

b) Ha nem érkezik az SU készlethez rendelt nyugtázás a rendeltetési GES-től tA4A másodperccel (4. Fejezet 4. Függelék) a készlet utolsó SU-ja (akár az eredeti készlet vagy az eredeti készletnek megfelelő adás-ismétlő készlet SU-i) továbbításának időpontja óta, vagy a 4.6.5.2.6 b) pontban meghatározottak szerint figyelmen kívül hagyták, akkor az AES-nek egy nyugtázási kérelmet, (RQA) SU-t (4. Fejezet 2. Függeléke A2-48. táblázat) kell továbítania. Ezt követően az AES-nek egy R-csatorna kiválasztására kell utasítást adni, és az előző RQA SU továbbítását követő minden tA4B másodpercben (4. Fejezet 4. Függeléke) újra továbbítania kell az RQA SU-t, amíg egy megfelelő TACK SU érkezik. Ugyanakkor, ha nem érkezik egy megfelelő TACK SU tA4B másodpercen belül, az ötödik RQA SU kibocsátása után, akkor az AES-nek egy hibát jelző átviteli állapotjelző LIDU-t (4-25. táblázat) kell küldenie az adatkapcsolati szolgáltatás felhasználójának, és meg kell szüntetnie az SU készlet feldolgozását.

4.6.4.3 FÖLDI TELEPÍTÉSŰ FÖLDI ÁLLOMÁS (GES)

4.6.4.3.1 Egy bejelentkezett AES-től érkező SU-kat a GES-nek újra össze kell rendeznie, és az AES ID-jének, Q számának, referencia számának és sorszámának megfelelően készletekbe kell rendeznie, amint az a 4. Fejezet 3.Ffüggelékében meg van határozva. A vett SSU-t figyelmen kívül kell hagyni, ha a megfeleleő ISU vagy RTX SU nem érkezett meg.

Megjegyzés. – Egy T-csatorna impulzus-köteghez társított AES ID meghatározható akár az impulzus-köteg ID SU-jából, ha az megérkezett, vagy az ugyanazon impulzus-kötegen belüli bármely olyan SU-ból, amely egy AES ID mezőt tartalmaz.

4.6.4.3.2 Egy ISU vételét követően a GES-nek meg kell állapítania, hogy a vett ISU által fejrészelt SU készletnek megfelelő további SSU-k várhatók-e vagy sem az AES-től a következő kritériumoknak megfelelően:

Nem várnak az SU készletnek megfelelő további SSU-kat, amennyiben akár a készlet utolsó SSU-ja, akár ugyanazon AES kisebb Q számú SU-ja, vagy ugyanazon AES azonos Q számú, de eltérő referencia számú SU-ja, vagy az AES ID-nek megfelelő kitöltő SU-ja érkezik meg.

4.6.4.3.3 Amikor nem várnak egy SU készletnek megfelelő több SU-t, akkor a GES-nek meg kell határoznia, hogy vannak-e a vett SU készletben hiányzó SU-k. Ezt követően a GES-nek a következőket kell végrehajtania:

a) ha az SU készlet teljes, akkor egy T-csatorna nyugtázási (TACK) SU-t (4. Fejezet 2. Függeléke A2-29. ábra) kell küldenie jelezvén, hogy nincsenek hiányzó SU-k, valamint az SU készletből a 4.6.3.4 pont szerint egy LIDU-t kell összeállítania és azt továbbítania kell az adatkapcsolati szolgáltatás megfelelő felhasználójához;

b) ha az SU készlet nem teljes, akkor egy vagy több, a hiányzó SU-kat azonosító TACK SU-t kell továbbítania az AES-hez a következők szerint:

1) ha az SU készletből több mint 42, vagy kevesebb mint 4 SU hiányzik, akkor csak egy TACK SU-t (4. fejezet 2. függelék A2-29. ábra) kell küldeni. Az első esetben a TACK SU-nak a teljes SU készlet, amíg a második esetben az összes hiányzó SU újra-küldésére vonatkozó igényt kell jelölnie;

2) egyéb esetben az összes hiányzó SU-t jelölő, maximálisan 14 TACK SU-t (4. fejezet 2. függeléke A2-29. ábra) kell az AES felé elküldeni.

4.6.4.3.3.1 Ha a vett SU készlet a GES-nél befejezésre váró újra-továbbított SU készlettel azonos, akkor a GES-nek ezeket a készleteket egy olyan új SU készlet kialakítására kell felhasználni, ami a lehetőség szerint a legteljesebb, mielőtt a 4.6.4.3.3 a) és b) pontokban megadottak szerint nyugtázást küld.

4.6.4.3.3.2 Minden befejezett SU készlet esetében a GES-nek figyelmen kívül kell hagynia az összes rákövetkező azonos Q számú, AES ID-jű és referencia számú SU készletet (teljes vagy nem teljes), amíg egy azonos Q számú, AES ID-jű és párosított referencia számú (a 4.6.5.2.2 pontban megadott párosítási sémának megfelelően) SU készlet érkezik.

4.6.4.3.4 Egy RTX SU vételét követően (4. fejezet 2. függeléke A2-41. ábra) a GES-nek a 4.6.4.3.2 pontban meghatározott feltételek szerint meg kell határoznia, hogy a vett RTX SU által fejrészezett, az újra-továbbított készletnek megfelelő további SU-k várhatók-e az AES-től. Amikor még nem számítanak újabb SU-kra, akkor a GES-nek az újra-továbbított SU-kat a megfelelő (nem teljes) SU készletbe kell behelyeznie és a 4.6.4.3.3 pont szerint nyugtáznia kell.

4.6.4.3.5 Az AES-től érkező nyugtázási (RQA) SU-ra vonatkozó igényre a GES-nek az RQA SU-ban jelzett SU készletnek megfelelő legutoljára küldött TACK SU-k készletének újra-továbbításával kell válaszolnia. Ha az RQA SU egy olyan befejezésre váró SU készletet azonosít a GES-nél, amelyhez nem továbbítottak TACK SU-t, akkor a GES-nek a hiányzó SU-k újra-továbbítását kérő TACK SU-t kell küldenie. Ha az RQA SU a GES-nél nem vett SU készletet azonosít, akkor a GES-nek a teljes SU készlet újra-továbbítását kérő TACK SU-t kell elküldenie.

4.6.4.3.6 Ha a GES egy befejezésre váró SU készlet AES ID-jével és Q számával és a 4.6.5.2.2 pontban megadott párosítási sémának megfelelően az SU készlet referencia számához párosított referencia számmal megegyező ISU-t vesz, akkor a GES-nek figyelmen kívül kell hagynia a várakozó SU készletet.

4.6.5 T-csatorna foglalási protokol

Megjegyzés. – A 4.6.5 pontban használt "AES" és "GES" kifejezések az AES és GES-ben belüli T-csatorna foglalási protokoll adatkapcsolati réteg funkcióira vonatkoznak.

4.6.5.1 ÁLTALÁNOS

A T-csatorna foglalási protokolok esetében az adatkapcsolati réteg funkcióknak meg kell felelni a 4.6.5.2 és
a 4.6.5.3 pontokban meghatározottaknak.

4.6.5.2 LÉGIJÁRMŰ FEDÉLZETÉN ELHELYEZETT FÖLDI ÁLLOMÁS (AES)

4.6.5.2.1 Egy 33 oktettet meghaladó LSDU-t tartalmazó LIDU vételekor az AES-nek a LIDU-t a T -csatorna protokolhoz kell irányítania.

Megjegyzés. – Egy 33 vagy kevesebb oktettből álló LSDU-t tartalmazó LIDU az R-csatorna protokolhoz vagy a T -csatorna protokolhoz irányítható.

4.6.5.2.2 A LIDU-knak a T-csatorna protokolhoz való továbbítása előtt az AES-nek ki kell jelölnie számára egy rendelkezésre álló (még ki nem jelölt) referencia számot (4. fejezet 3. függeléke 46. tétel). Ha egy LIDU-nak nem jelölnek ki referencia számot, akkor a LIDU-t addig kell tárolni, amíg egyet kijelölnek a számára. Minden egyes referencia szám kijelölését a referencia szám nélküli legrégebben vett LIDU részére kell elvégezni. A T-csatorna LIDU részére kijelölendő referencia számokat párokként kell meghatározni úgy, mint (0, 1); (2, 3); (4, 5); (6, 7); (8, 9); (10, 11); (12, 13); (14, 15). Ha egyszer felszabadították, egy párból nem szabad referencia számot újra kijelölni, addig, amíg a pár másik számát ki nem jelölik és fel nem szabadítják. Az AES nem jelölhet ki egy olyan párból referencia számot, amelynek másik számát éppen felszabadították, addig, amíg a felszabadítás előtt a kijelölésre rendelkezésre álló összes párból referencia számokat ki nem jelölnek. A kijelölt referencia számot kell használnia mind a T-csatorna átviteli protokolnak, mind a T-csatorna foglalási protokolnak.

4.6.5.2.3 Egy SU készlet továbbításának foglalására szolgáló kéréshez az AES-nek a foglalást kérő (REQ) SU-t kell küldenie a GES-nek, amely jelzi a referencia számot, Q számot és a továbbítandó SU készlet hosszát.

4.6.5.2.4 Az AES-nek a REQ SU-t kell továbbítania az R-csatornán (4. fejezet 2. függeléke A2-47 ábra) vagy a T-csatornán (4. fejezet 2. függeléke A2-7. ábra) a GES részére a következő követelménynek megfelelően:

A T-csatornát kell használni, ha az AES éppen egy T-csatorna bekezdő jelszakaszt továbbít, és elegendő hely van a REQ SU tárolására, vagy ha éppen egy T-csatorna bekezdő jelszakasz indítása esedékes a következő 8 másodperces idő-ablakon belül; egyéb esetekben az R csatornát kell használni.

4.6.5.2.5 Amikor a T-csatornát használják egy REQ SU továbbítására a GES részére, akkor a kért hosszúságot egy SU-val meg kell növelni.

4.6.5.2.6 Egy REQ SU-nak a GES-hez való elküldését követően az AES-nek a következőket kell végrehajtania:

a) Ha a T-csatornát egy REQ SU továbbítására használták és sem egy megfelelő foglalási (RES) SU (4. fejezet 2. függeléke A2-23. ábra), sem egy megfelelő rövidesen megjelenő foglalási (RFC) SU (4. fejezet 2. függeléke A2-24. ábra) nem érkezik GES-től tA6 másodpercen belül (4. fejezet 4. függeléke) azon időponttól számítva, hogy a REQ SU-t elküldték a T-csatornán, akkor az AES-nek a 4.6.5.2.4 pont szerint a REQ SU-t ismét el kell küldenie a T- vagy R-csatornán az utoljára kért hosszal azonos továbbítási hosszal, vagy ha a T-csatornát használják, eggyel megnövelt hosszal. Ezt követően az AES-nek a 4.6.5.2.6 pont szerint kell eljárnia.

b) Ha az R-csatornát használták az REQ SU továbbítására, és egy megfelelő RFC SU nem érkezett a GES felől a tA7 másodpercen belül (4. fejezet 4. függeléke) azon időponttól, hogy a REQ SU-t az R-csatornán elküldték, akkor az AES-nek utasítást kell adni egy R-csatorna frekvencia kiválasztására és a 4.6.5.2.4 ponttal összhangban ismét el kell küldenie a REQ SU-t a T- vagy R-csatornán azzal a kért átviteli hosszal, amely egyenlő az utoljára kért hosszal, vagy eggyel hosszabb, ha a T-csatornát használják. Ezt követően az AES-nek a 4.6.5.2.6 pontban foglaltak szerint kell eljárnia. Ugyanakkor, ha tA7 másodperc eltelik a REQ SU R-csatornán való egymást követő ötödik továbbítása után anélkül, hogy megfelelő RES SU vagy RFC SU érkezne a GES-től, akkor az AES-nek meg kell szakítania a megfelelő LIDU fenntartási eljárását és figyelmen kívül kell hagynia az utoljára kibocsátott REQ SU-ban azonosított SU-k számát. Ha a figyelmen kívül hagyott SU-k között van egy ISU, akkor az AES-nek a figyelmen kívül hagyott ISU által fejrészezett teljes SU készletet figyelmen kívül kell hagynia még akkor is, ha az a REQ SU-ban azonosított SU-k számánál több SU figyelmen kívül hagyását eredményezi. Ezt követően az AES-nek a teljesen figyelmen kívül hagyott SU készletre vonatkozó, hibát jelző átviteli állapotjelző LIDU-t (4-25. táblázat) kell küldenie az AES adatkapcsolati szolgáltatás megfelelő felhasználójához. Ha a figyelmen kívül hagyott SU-k között van egy RTX SU, akkor az AES-nek az RTX SU által fejrészelt teljes SU készletet figyelmen kívül kell hagynia. Ha a figyelmen kívül hagyott SU-k között van egy REQ SU, akkor az AES-nek a 4.6.5.2.4 pont szerint a REQ SU-t ismét újra-továbbítania kell az R- vagy T-csatornán.

c) Ha a GES-től egy REQ SU-nak megfelelő RES SU érkezik, akkor az AES-nek a RES SU-ban lévő foglalási információt a T-csatorna átviteli protokolhoz kell küldenie. A T-csatorna bekezdő jelszakaszban a foglalási kezdő keretszámnak vagy az aktuális keretszámra vagy az aktuális keretszámot követő 15 keret egyikére kell vonatkoznia.

d) Ha a GES-től egy REQ SU-nak megfelelő RFC SU érkezik, akkor az AES-nek ki kell számolnia a tA8-at (4. fejezet 4. függeléke) a várhatóan megérkező RES SU részére az RFC SU-ban meghatározott késésnek megfelelően. Ezt követően az AES-nek a következőket kell elvégeznie:

1) Ha nem érkezik a GES-től az RFC SU készletnek megfelelő RES SU vagy RFC SU az RFC SU vételét követő tA8 másodpercen belül, akkor az AES-nek a 4.6.5.2.4 ponttal összhangban egy REQ SU-t kell küldenie a T- vagyaz R-csatornán a GES-nek, amelynek a hosszúsága megegyezik a megfelelő RFC SU-hoz rendelt hosszúsággal, vagy eggyel nagyobb, ha a T-csatornát használják. Ezt követően az AES-nek a 4.6.5.2.6 pont szerint kell eljárnia.

2) Ha a GES-től egy először vett REC SU-hoz kapcsolódó RFC SU érkezik, akkor az AES-nek fel kell frissítenie a megfelelő tA8-at a RFC SU-ban meghatározott új késésnek megfelelően;

3) Ha a GES-től egy, az RFC SU-nak megfelelő RES SU érkezik, a tA8 másodpercen belül, attól az időtől számítva, amikor a RFC SU vételre került, az AES-nek a RES SU-ban lévő foglalási információt a T-csatorna átviteli protokolhoz kell elküldeni;

4.6.5.2.7 Amikor az AES T-csatorna átviteli protokolja egy olyan TACK SU-t vesz, ami hiányzó SU-k újra-ismétlését kéri, akkor az AES-nek ki kell számítania a tA8-at, annak a késésnek megfelelően, ami a TACK SU-ban meghatározott a várható RES SU érkezésére. Az AES-nek ezután a következőket kell végrehajtania:

a) Ha nem érkezik a GES-től a TACK SU-nak megfelelő RES SU vagy RFC SU, a SU teljes vételét követő tA8 másodpercen belül, akkor az AES-nek egy olyan REQ SU-t kell elküldenie a GES részére a T- vagy az R-csatornán a 4.6.5.2.4 pontban leírtaknak megfelelően, amelynek a hosszúsága megegyezik a TACK SU készletből hiányzó SU-k számának hosszúságával, vagy eggyel nagyobb, ha a T-csatornát használják és az AES-nek ezt követően a 4.6.5.2.6 pont szerint kell eljárnia.

b) Ha a GES-től egy előzően vett TACK SU készlethez kapcsolódó RFC SU érkezik, akkor az AES-nek fel kell frissítenie a megfelelő tA8-at az RFC SU-ban meghatározott új késésnek megfelelően.

c) Ha a GES-től egy RES SU érkezik a teljes TACK SU vételét követő tA8 másodpercen belül, akkor az AES-nek a RES SU-ban lévő foglalási információt az AES T-csatorna átviteli protokoljához kell küldenie.

Megjegyzés. – A RES-ben vagy RFC SU-ban lévő RFC jelző mező (4. fejezet 3. függeléke 50. tétel) szerepe az, hogy különbséget tegyen a REQ SU-khoz rendelt RES vagy RFC SU-k, és a TACK SU-k vagy RFC SU-khoz rendelt RES vagy RFC SU-k között.

4.6.5.2.8 Ha egy olyan RES SU érkezik a GES-től, amely nem egyezik meg az AES által küldött egyetlen REQ SU-val vagy RFC SU-val vagy az AES által vett TACK SU-val sem, akkor az AES-nek a RES SU-ban lévő foglalási információt a T-csatorna átviteli protokolhoz kell küldenie.

4.6.5.2.9 Ha az AES nem képes a kijelölt T-csatorna bekezdő jelszakasz foglalására egy T- csatorna bekezdő jelszakaszt továbbítani, akkor az AES-nek egy, a nem továbbított bekezdő jelszakasz foglalást kérő REQ SU-t kell küldenie a GES-nek.

4.6.5.2.10 Amikor egy AES egy átadási eljárás (4.9) eredményeként befejezi egy GES-sel az összeköttetést, akkor mind az AES-nek, mind a GES-nek fel kell szabadítaniuk az adatkapcsolati réteg összes forrását, amelyeket adat-összeköttetés céljára közöttük kiosztottak.

4.6.5.2.11 Egy LIDU számára kijelölt referencia számot fel kell szabadítani, ha a LIDU-nak megfelelő SU készlethez kapcsolódó várható foglalásokat az AES-nél vették, vagy a LIDU-nak megfelelő foglalási eljárást megszakították, valamint egy sikeres átvitelt vagy hibát jelző átviteli állapotjelző LIDU (4-25. táblázat) az adatkapcsolati réteg felhasználójához való kibocsátása után.

4.6.5.3 FÖLDI TELEPÍTÉSŰ FÖLDI ÁLLOMÁS (GES)

4.6.5.3.1 Az AES-től érkező REQ SU vételekor a GES-nek a REQ SU-ban azonosított SU készlet részére ki kell jelölnie egy vagy több bekezdő jelszakasz foglalást az AES felé. Amikor a GES egy hibát jelző TACK SU készletet továbbít az AES felé, akkor a GES-nek ki kell jelölnie egy vagy több, egy RTX SU-ból és az azt követő hiányzó SU-kból álló részleges SU készlet újra- továbbítására szolgáló bekezdő jelszakasz foglalást.

Megjegyzés. – Egy hibát jelző TACK SU a következő RES SU számára előre beállított késést meghatározó mezőt tartalmaz.

4.6.5.3.2 A GES-nek egy RES SU-t kell küldenie az AES felé egy olyan adott időpontban, hogy az egy rákövetkező 8 másodperces maximális késést biztosítson a tervezett SU készlet adásideje előtt. Ha a kiosztott foglalás időpontjának kezdésse kívül van a 8 másodperces időablakon, akkor a GES-nek egy RFC SU-t kell küldenie az AES részére a késést jelezve, és azt követően kell a RFC SU-t elküldenie, miután a tényleges időpont a beütemezett foglalási időponttól számított 8 másodpercen belül van. Ha egy hibákat jelző TACK SU készlettel társított foglalás, vagy korábban továbbított RFC SU nem hajtható végre a TACK SU készletben, vagy az RFC SU-ban meghatározott késési tartományon belül, akkor a GES-nek egy RFC SU-t kell küldenie az AES felé mielőtt a késési periódus eltelik. Az RFC SU-nak egy új késést kell jeleznie a foglaláshoz. A GES-nek egy RES SU-t kell küldeni az AES-nek annyival korábban, hogy az időben megérkezzen ahhoz, hogy az AES egy SU készlet küldését megkezdje a foglalási kötegelt adatátvitel kezdetekor.

4.6.5.3.3 A GES nem jelölhet ki egymást átfedő foglalásokat ugyanazon a -csatornán. Egy foglalás vége és a következő foglalás kezdete közötti időintervallumnak elegendő hosszúnak kell lennie ahhoz, hogy biztosítsa azt, hogy a GES által foglalt T-csatorna bekezdő jelszakaszok nem fedik át egymást. Egy hosszú SU készletet szünetekkel elválasztott többszörös bekezdő jelszakaszokkal kell kijelölni. A különböző SU készletek részére a többszörös bekezdő jelszakasz foglalásoknak vagy egyedi foglalásoknak olyannak kell lenniük, hogy lehetővé tegyenek legalább egy R-csatorna bekezdő jelszakasz adást minden 8. másodpercben. A T-csatorna bekezdő jelszakasz hosszúságát úgy kell megválasztani, hogy az biztosítsa azt, hogy az R- és T-csatorna adások megfelelnek a 4.7 pontban foglalt teljesítmény követelményeknek. Minden foglalásos bekezdő jelszakasz hosszúságának elegendőnek kell lenni azon bekezdő jelszakasz azonosító SU elhelyezésére, amely bevezet minden egyes T-csatorna bekezdő jelszakaszt, valamint a teljes foglalási hosszúságnak a kértnél legalább egy SU-val hosszabbnak kell lennie. A GES-nek olyan foglalásokat kell alkalmaznia, hogy ne kelljen soha egyetlen adott AES-től sem megkívánni az AES-hez kijelölt T- csatornák csoportjához tartozó, egynél több T-csatornán történő adást.

4.6.6 Alsáv C-csatorna a légijárműhöz protokol

Megjegyzés. – Ebben az alfejezetben az AES és GES kifejezések használata a GES-en és AES-en belüli, a légijárművek felé irányuló alsávi C csatorna adatkapcsolati réteg funkciókra vonatkozik.

4.6.6.1 ÁLTALÁNOS

A légijárművek felé irányuló egyedi alsávi C-csatorna adatkapcsolati réteg funkcióknak a 4.4.4.2 és 4.6.6.3 pontokban meghatározottaknak kell lenni.

4.6.6.2 FÖLDI TELEPÍTÉSŰ FÖLDI ÁLLOMÁS (GES)

4.6.6.2.1 Az áramkör üzemmódú összeköttetési szolgáltatás felhasználójától (4-38. táblázat), vagy GES vezérléstől (4-45. táblázat) kapott LIDU vételekor a GES-nek a LIDU-ból elő kell állítania egy SU készletet. Minden SU készletnek vagy egy egyedüli jel egységből, amelyet "egyedüli jel egység"-nek (LSU) neveznek, vagy több olyan jel egységből kell állnia, amelyekből az első egy "kezdeti jel egység" (ISU) és az azután következők a "soronkövetkező jel egységek" (SSU). A jel egységet a LICI-ben lévő információ leképezésével és a belső adatkapcsolati réteg protokol folyamatok által a megfelelő jel egység szabályozó információs mezejébe generálva kell előállítani.

4.6.6.2.2 Az összes adásra váró jel egység közül a legrégebbi, legmagasabb Q számmal rendelkező jel egységet kell elsőnek továbbítani. Egy többszörös jel egységekből álló jel egység készlet jel egységeit sorszámaik csökkenő sorrendjében kell továbbítani (4. Fejezet 3. fFggeléke, 59. tétel).

Megjegyzés. – Az alsávi C-csatorna adatkapcsolati réteg a GES-ben nem jelöl ki az áramkör üzemmódú összeköttetési szolgálat felhasználójától kapott LIDU-nak referencia számot. Ehelyett alkalmazási referencia számot jelöl ki az áramköri üzemmódú szolgálat, és ezt juttatják el a LICI-ben lévő adatkapcsolati réteghez.

4.6.6.2.3 Ha nincsenek továbbítandó jel egységek, akkor a GES-nek kitöltő jel egységeket kell küldenie (4. Fejezet 2 Függelék, A2-42. ábra).

4.6.6.3 LÉGIJÁRMŰ FEDÉLZETEN ELHELYEZETT FÖLDI ÁLLOMÁS (AES)

4.6.6.3.1 Egy egyedüli jel-egységből álló jel-egység készlet részére az AES-nek egy olyan LIDU-t kell előállítania, amely csak LICI-t tartalmaz, és a LIDU-t továbbítania kell a megfelelő össze- köttetési szolgáltatás felhasználójához az AES-ben. A LICI-t a beérkezett egyedüli jel-egység szabályozó információjából kell létrehozni.

4.6.6.3.2 Többszörös jel egységekből álló jel egység készlet részére az AES-nek a beérkezett jel egységeket újra kell társítani és rendezni egy jel egység készletbe az alkalmazási referencia száma (4. fejezet 3. függeléke, 4. szakasz), sorszámai (4. Fejezet 3. Függelék 59. szakasz), és Q számai (4. fejezet 3. függelék 43. szakasz) alapján. Egy kezdeti jel egység vételét követően az AES-nek meg kell határoznia, hogy várható-e a GES-től a kezdeti jel egység által fejrészezett jel egység készletnek megfelelő további rákövetkező jel egység a következő kritériumoknak megfelelően:

Nem várhatók a jel egység készletnek megfelelő további egyedülálló jel egységek, ha akár a jel egység készlet utolsó egyedülálló jel egysége, vagy egy kitöltő jel egység érkezik, vagy ha a csatorna bontódik.

Ha egy olyan kezdeti jel egység vagy egyedülálló jel egység érkezik, amelynek Q száma megegyezik a befejezésre váró jel egység készlet Q számával, akkor az AES-nek érvénytelenítenie kell a befejezésre váró, nem teljes jel egységet.

4.6.6.3.2.1 Ha nem várhatók további jel egységek, amelyek megfelelnek egy jel egység készlet továbbításához, akkor az AES-nek meg kell határoznia, hogy vannak-e hiányzó jel egységek. Az AES-nek a továbbiakban a következőket kell végrehajtania:

a) ha nincsenek hiányzó jel egységek, akkor az AES-nek a 4.6.3.4.3 pont szerint újra össze kell állítania a jel egységeket egy LIDU-ba, és azt továbbítania kell a megfelelő összeköttetési szolgáltatás felhasználójához az AES-ben;

b) ha van hiányzó jel egység, akkor az AES nem állíthat elő LIDU-t a beérkezett hiányos jel egység készletből; helyette tárolnia kell a beérkezett jel egységeket, amíg a többi hiányzó jel egység a jel egység készlet újra-továbbításakor megérkezik, vagy amíg a csatorna bontódik.

4.6.6.3.3 *C-csatorna áthallás érzékelése.* Ha egy beérkezett jel egység vagy jel egység készlet egy olyan AES azonosítót (ID) vagy alkalmazási referencia számot tartalmaz, amely különbözik a C- csatorna létrehozásakor meglévőtől, akkor az AES-nek az AES vezérlést utasítania kell, hogy akadályozza meg a C-csatorna frekvenciáján történő adást, és utasítania kell az AES áramköri üzemmódú szolgálatot a hívás befejezésére.

4.6.7 A légijárműtől jövő alsávi C-csatorna protokolja

Megjegyzés. - A 4.6.7 pontban az AES és GES kifejezések használata az AES-en és a GES-en belül a légijárműtől jövő alsávi C-csatorna adás adatkapcsolati réteg funkciókra vonatkozik.

4.6.7.1 ÁLTALÁNOS

A kapcsolati réteg funkcióknak egy, a légijárműtől jövő adás egyedi alsávi C-csatorna esetében a 4.6.7.2 és a 4.6.7.3 pontokban foglaltaknak kell megfelelniük.

4.6.7.2 LÉGIJÁRMŰ FEDÉLZETÉN ELHELYEZETT FÖLDI ÁLLOMÁS (AES)

4.6.7.2.1 Az áramkör üzemmódú kapcsolat szolgáltatás felhasználójától (4-38. táblázat), vagy az AES vezérléstől (4-44. táblázat) kapott LIDU vételekor az AES adatkapcsolati rétegnek a 4.6.6.2.1 pont szerint elő kell állítania a megfelelő jel egység készletet.

4.6.7.2.2 Az összes adásra váró jel egység közül a legrégebbi, legnagyobb Q számmal rendelkező jel egységet kell elsőnek továbbítani. Egy többszörös jel egységekből álló jel egység készlet jel egységeit sorszámaik csökkenő sorrendjében kell továbbítani (4. fejezet 3. függeléke, 59. tétel).

Megjegyzés. – Az alsávi C-csatorna adatkapcsolati réteg az AES-ben nem jelöl ki az áramkör üzemmódú kapcsolat szolgáltatás felhasználójától kapott LIDU-nak referenci azámot. Ehelyett alkalmazási referencia számot jelölnek ki az áramkör üzemmódú szolgálatok és ezt juttatják el a LICI-ben lévő adatkapcsolati réteghez.

4.6.7.2.3 Ha nincsenek továbbítandó jel egységek, akkor az AES-nek kitöltő jel egységeket kell küldenie (4. fejezet 2. függeléke, A2-42. ábra).

4.6.7.3 FÖLDI TELEPÍTÉSŰ FÖLDI ÁLLOMÁS (GES)

4.6.7.3.1 Egy egyedülálló jel egységekből álló jel egység készlet részére a GES-nek a 4.6.6.3.1 pont szerinti LIDU-t kell előállítania és továbbítania a GES-ben lévő kapcsolat szolgáltatás felhasználójához.

4.6.7.3.2 Többszörös jel egységekből álló jel egység készlet részére a GES-nek a beérkezett jel egységeket újra kell társítani és rendezni egy jel egység készletbe az alkalmazási referencia száma (4. fejezet 3. függeléke, 4. tétel), sorszámai (4. fejezet 3. függelék 59. tétel) és Q számai (4. fejezet 3. függelék 43. tétel) alapján. Egy kezdő jel egység /ISU/ vételét követően a GES-nek meg kell határoznia, hogy várható-e az AES-től a kezdő jel egység által fejrészezett jel egység készletnek megfelelő további soronkövetkező jel egységek /SSUk/ a következő követelménnyel összhangban:

Nem várhatók a jel egység készletnek megfelelő további egyedüli jel egységek, ha akár a jel egység készlet utolsó egyedüli jel egysége, vagy egy kitöltő jel egység érkezik, vagy ha a csatorna bontódik.

Ha egy olyan kezdő jel egység /ISU/ vagy egyedüli jel egység /LSU/ érkezik, amelynek Q száma megegyezik az előállításra váró jel egység készlet Q számával, akkor a GES-nek érvénytelenítenie kell az előállításra váró, nem teljes jel egység készletet.

4.6.7.3.2.1 Ha nem várhatók további olyan jel egységek, amelyek megfelelőek egy jel egység készlet továbbításához, akkor a GES-nek meg kell határoznia, hogy vannak-e hiányzó jel egységek. A GES-nek a továbbiakban a következőket kell végrehajtania:

a) ha nincsenek hiányzó jel egységek, akkor a GES-nek a 4.6.3.4.3 pont szerint újra össze kell állítania a jel egységeket egy LIDU-ba és azt továbbítania kell a megfelelő kapcsolat szolgáltatás felhasználójához a GES-be;

b) ha van hiányzó jel egység, akkor a GES nem hozhat létre LIDU-t a beérkezett hiányos jel egység készletből; helyette tárolnia kell a beérkezett jel egységeket addig, amíg a többi hiányzó jel egység a jel egység készlet újra-továbbításakor megérkezik, vagy amíg a csatorna bontódik.

4.7 MŰHOLDAS AL-HÁLÓZATI RÉTEG

4.7.1 Általános előírások

4.7.1.1 ARCHITEKTÚRA

4.7.1.1.1 A műholdas al-hálózati rétegnek (SSNL) az AES-ben és a GES-ben kapcsolat-orientált kötegelt adatszolgáltatást kell biztosítani az al-hálózati szolgáltatás (SNS) felhasználói közötti al-hálózati kapcsolatok (SNCS) létrehozásával. Az AES-ben és GES-ben a műholdas al-hálózati rétegnek /SSNL/ az alábbi három funkciót kell tartalmaznia:
a) műholdas al-hálózat-függő (SSND) funkció;
b) al-hálózati hozzáférési (SNAc) funkció; és
c) egybedolgozó (IW) funkció.
A műholdas al-hálózat-függő (SSND) funkcionak kell végrehajtani a műholdas al-hálózat-függő protokolt (SSNDP) az AES és a GES minden párja között az al-hálózati protokol adategységek (SNPDU) cseréjével. Végre kell hajtania az SSNDP légijármű (SSNDPA) funkciót az AES-ben és az SSNDP föld (SSNDPG) funkciót a GES-ben. Az al-hálózati hozzáférési funkciónak kell végrehajtani az ISO 8208 protokolt az AES vagy GES és a csatolt útvonal-kiválasztó között ISO 8208-as csomagok cseréjével. Végre kell hajtania az ISO 8208 DCE funkciót az AES-ben és GES-ben. Az IW funkciónak (IWF) kell biztosítania a szükséges harmonizációs funkciókat az SSND, az SNAc és a DN funkciók között. A 4-11. ábra mutatja az SSND, IW és SNAc funkciókat, valamint az ATN műholdas al-hálózati protokol felépítését.

4.7.1.1.2 A DCE kifejezésnek a használatakor az ISO 8208 DCE jelentéssel kell bírnia.

4.7.1.1.3 Az SSNL-nek az adatkapcsolati réteggel és az AES/GES vezérléssel kell illeszkednie.

4.7.1.2 SZOLGÁLTATÁSOK

A Műholdas al-hálózati réteg-/SSNL/-nek a következő szolgáltatásokat kell biztosítania:

a) a továbbított információ átláthatósága – biztosítania kell az oktett-igazított SSNL felhasználói adat és/vagy ellenőrző információt; és

b) a szolgáltatás kiválasztás minősége – eszközt kell biztosítani az SNS felhasználók részére, hogy kérjék és elfogadják az SSNL felhasználói adatok átvitelére a szolgáltatás minőségét.

4.7.2 Adatcsomag teljesítmény

4.7.2.1 MEGHATÁROZÁSOK

4.7.2.1.1 Az adatcsomag teljesítménnyel kapcsolatos kifejezések az ISO 8348-ban (első kiadás) található meghatározásokon alapulnak. Az AMSS al-hálózati rétegre alkalmazott meg- határozásokban az ISO 8348-ban szereplő "hálózat" szót és rövidítését, az "N"-t felváltja az "al-hálózat" és rövidítése az "SN", ahol csak előfordulnak. A további meghatározások a következők:

4.7.2.1.2 *Adat-átviteli késés (95 százalékos).* A késések statisztikai eloszlásának 95 százaléka, amelynél az átviteli késés az átlag.

4.7.2.1.2 *bis Adat-továbbítási késés.* Az ISO 8348-nak megfelelően az adatkésések statisztikai eloszlásának
átlagértéke.

4.7.2.1.3 *Al-hálózati szolgáltatási adat-egység (SNSDU).* Az al-hálózati felhasználói adatok mennyisége, amelynek identitását megőrzik az al-hálózati kapcsolat egyik végétől a másikig.

Megjegyzés. – Az al-hálózati teljesítmény egy sor tényezőtől függ, ideértve az összeköttetési forgalom szintjét is. Az itt megadott teljesítmény értékek a csúcsforgalmi órákra vonatkoznak.

4.7.2.2 A SZOLGÁLTATÁS SEBESSÉGE

4.7.2.2.1 *KAPCSOLAT LÉTREHOZÁSI KÉSÉS*

Megjegyzés. – A kapcsolat létrehozási késés, amint azt az ISO 8348 meghatározza, magában foglal egy olyan összetevőt, ami a hívott al-hálózati szolgáltatás felhasználójának tulajdonítható, ami az SN-KAPCSOLÁS jelzése és az SN-KAPCSOLÁS válasza közötti idő. Ez a felhasználói összetevő a műholdas al-hálózat határain kívüleső eseményeknek köszönhető és ezért nem tartozik az AMSS műszaki paraméterei közé.

4.7.2.2.1.1 A kapcsolat létrehozási késés nem haladhatja meg a következő maximális értékeket:

Az AES által használt minimális csatorna átviteli sebesség (bit/s)	Maximális kapcsolati késés (95 százalék) (másodperc)
600	70
1200	45
2400	25
4800	25
10500	25

4.7.2.2.2 *ADAT-TOVÁBBÍTÁSI KÉSÉS*

Megjegyzés. – Az ISO 8348-cal összhangban az adat-továbbítási késés értékei egy 128 oktett rögzített hosszúságú SNSDU-n alapszanak. Az adat-továbbítási késéseket átlag-értékekként határozzák meg. (A 4.7.2.1.2 és a 4.7.2.1.2 bis pontok a vonatkozóak.)

4.7.2.2.2.1 Az adat-továbbítási késés nem haladhatja meg a következő maximális értékeket:

Az AES által használt minimális csatorna-átviteli sebesség (bit/s)	Maximális adat-továbbítási késés (másodperc)		
	Légijárműhöz		Légijárműtől
	Legmagasabb elsőbbségű szolgáltatás	Legalacsonyabb elsőbbségű szolgáltatás	Legmagasabb elsőbbségű szolgáltatás
600	12	40	40
1200	8	25	30
2400	5	12	15
4800	4	7	13
10500	4	5	13

Megjegyzés. – Bármely AES-ben a légijárműtől érkező kisebb elsőbbségű forgalom további késéseket szenvedhet a légijárműtől érkező forgalmi terhelés mennyiségétől és sebességétől függően.

4.7.2.2.3 *ADAT-ÁTVITELI KÉSÉS (95 SZÁZALÉKOS)*

Megjegyzés. – Az ISO 8348-cal összhangban a 95 százalék adat-átvitel késési érték a rögzített 128 oktett SNSDU hosszúságon alapszik. A 95 százalékos adat-átviteli késés a 4.7.2.1.2 pontban van meghatározva.
Az adatátviteli késés (95 százalékos) nem haladhatja meg a következő maximális értékeket:

Az AES által használt minimális csatorna-átviteli sebesség (bit/s)	Maximális adat-átvitelii késés (95 százalék) (másodperc)		
	Légijárműhöz		Légijárműtől
	Legmagasabb elsőbbségű szolgáltatás	Legalacsonyabb elsőbbségű szolgáltatás	Legmagasabb elsőbbségű szolgáltatás
600	15	110	80
1200	9	60	65
2400	6	30	35
4800	5	20	30
10500	4	10	30

Megjegyzés. – Bármely AES-ben a légijárműtől érkező alacsonyabb elsőbbségű forgalom további késéseket szenvedhet a légijárműtől érkező forgalmi terhelés mennyiségétől és sebességétől függően.

4.7.2.2.4 *KAPCSOLAT-BONTÁSI KÉSÉS*

A kapcsolat-bontási késés (95 százalékos) nem haladhatja meg a 30 másodpercet.

4.7.2.3 A SZOLGÁLTATÁS MEGBÍZHATÓSÁGA

4.7.2.3.1 *MARADÉK-HIBA ARÁNY*

A maradék-hiba arány a légijárműtől érkező adásban nem haladhatja meg a 10^{-4} per al-hálózati szolgáltatási adat egység-/SNSDU/-t. A maradék-hiba arány a légijármű részére továbbított adásban nem haladhatja meg a 10^{-6} per SNSDU-t.

Megjegyzés. – A maradék-hiba arány magában foglalja a fel nem ismert hiba valószínűségét, egy SNSDU elvesztésének a lehetőségét és egy SNSDU megduplázásának a valószínűségét.

4.7.2.3.2 *ÖSSZEKÖTTETÉSI HIBA TŰRÉS*

4.7.2.3.2.1 Egy al-hálózat kapcsolat /SNC/ szolgáltató által kezdeményezett SNC bontás valószínűsége nem haladhatja meg a 10^{-4}-t bármely egyórás időtartamon belül.

Megjegyzés. – A GES-től GES-nek történő átadásból vagy az AES kijelentkezésből, illetve a virtuális hívás /VC/ kizárólagos hozzárendelésből keletkező összeköttetés bontása ki van zárva ebből a műszaki leírásból.

4.7.2.3.2.2 Egy SNC szolgáltató által kezdeményezett visszaállítás valószínűsége nem haladhatja meg a 10^{-1}-t bármely egyórás időtartamon belül.

4.7.3 Műholdas al-hálózat-függő protokol szolgáltatások és üzemelések

4.7.3.1 ÁLTALÁNOS ELŐÍRÁSOK

Mivel a Műhold al-hálózat-függő funkció protokol, légijármű /SSNDPA/ és a Műhold al-hálózat-függő funkció protokol, föld /SSNDPG/ közötti funkcionális különbségek minimálisak, ezért üzemeléseiket az SSNDPX viszonylatában kell meghatározni, ahol az X jelentheti akár az A-t, akár a G-t. Ahol különbségek fordulnak elő, ott az SSNDPA és az SSNDPG funkciókat külön-külön kell meghatározni.

4.7.3.2 MŰHOLD AL-HÁLÓZAT-FÜGGŐ PROTOKOL ELTITÁSOK

Megjegyzés. – Minden egyes AES és GES pár között legalább egy pár SSNDPA és SSNDPG entitás van. A 4-12. ábra két pár SSNDPA és SSNDPG entitást ábrázol két AES és egy GES között.

4.7.3.2.1 Az ebben a részben meghatározott SSNDPX minden SSNDPX entitásra kell, hogy vonatkozzon.

4.7.3.3 LOGIKAI CSATORNÁK

Megjegyzés. – Az SSNDPA-k és SSNDPG-k közötti kapcsolatot logikai csatornákon keresztül hozzák létre. Minden SSNDPX entitás pár között maximálisan 255 csatorna hozható létre. Minden logikai csatornát saját 1-től 255-ig terjedő logikai csatornaszám (LCN) azonosítja. Az LCN 0 foglalt.

4.7.3.3.1 Egy új föld-levegő kapcsolat létrehozása céljából az SSNDPG-nek az 1-től 127-ig terjedő tartományból kell kijelölnie egy logikai csatorna számot a tartományban lévő legkisebb számú kész állapotú logikai csatorna kiválasztásával. Egy új levegő-föld kapcsolat felállításához az SSNDPA-nak a 128-tól 255-ig terjedő tartományból kell kijelölnie egy logikai csatorna számot a tartományban lévő legnagyobb számú kész állapotú logikai csatorna választásával.

4.7.3.4 ÜZEMELÉSEK

Az SSNDPX virtuális hívás szolgáltatásnak (VC) három megkülönböztethető fázison kell áthaladnia:

a) kapcsolat létrehozás;

b) adatátvitel; és

c) kapcsolat bontása.

Megjegyzés. – Az SSNDPX helyi kezdeményezésű, vagy távoli kezdeményezésű üzemelések fogalmaiban kerül meghatározásra. A helyi kezdeményezésű üzemelés az eljárást az SSNDPX-ben határozza meg a helyi SNS felhasználótól kiinduló üzemelések kezelése céljából, amíg a távoli kezdeményezésű az *eljárást az SSNDPX-ben a távoli SNS felhasználótól kiinduló üzemelések kezelése céljából határozza meg.*

4.7.3.5 KAPCSOLAT LÉTREHOZÁSA

Megjegyzés. – A kapcsolat létrehozása közben maximálisan 128 oktett felhasználói adat továbbítható.

4.7.3.5.1 A kapcsolat létrehozási eljárást minden kapcsolat létrehozási kérésre függetlenül alkalmazni kell.

4.7.3.5.2 A felhasználói adatokat mindkét irányban átlátható módon kell továbbítani.

4.7.3.5.3 *HELYI KEZDEMÉNYEZÉS*

4.7.3.5.3.1 *Szabvány üzemelés*

4.7.3.5.3.1.1 Amikor az SSNDPX egy hívás-kérési adatcsomagot fogad az IWF-től, akkor ki kell jelölnie egy kész állapotban lévő logikai csatornát egy kapcsolat-kérési SNPDU segítségével, a hívás-kérési adatcsomagot a távoli SSNDPX-hez kell továbbítania és a logikai csatornát az IWF hívás-kérési állapotba kell állítania.

4.7.3.5.3.1.2 Ha a hívást elfogadták a távoli SSNDPX-nél, akkor egy kapcsolat-megerősítő SNPDU érkezik. Ezt követően az SSNDPX-nek a logikai csatornát az adat-átviteli/forgalom-vezérlés (forgalom-vezérlés kész/nincs távoli vagy helyi megszakítás függőben) állapotba kell állítani, és egy hívás kapcsolva adatcsomagot kell továbbítania az IWF-hez. A hívás-kapcsolt adatcsomagnak alapértelmezési értékeket kell használni (ha vannak ilyenek) azon beállítások esetében, amelyek nem kerülnek továbbításra a műholdas al-hálózaton keresztül, a 4.7.3.16 pontban meghatározott SNPDU adatcsomag leképezési szabályok szerint.

4.7.3.5.3.1.3 Ha az SSNDPX nem kap sem egy kapcsolat-megerősítő, sem egy kapcsolat-bontási SNPDU-t a távoli SSNDPX-től mielőtt az időzítő (lásd tN1, 4-18. táblázat) lejár, akkor egy kapcsolat-bontási eljárást kell kezdeményeznie.

4.7.3.5.3.2 *Egyéb üzemelés*

Ha nem állnak rendelkezésre források, vagy egy megkívánt beállítási érték nem megengedett, akkor a kezdeményező SSNDPX-nek egy bontás-jelző adatcsomagot kell küldenie az IWF-nek.

4.7.3.5.4 *TÁVOLI KEZDEMÉNYEZÉS*

4.7.3.5.4.1 *Szabvány üzemelés*

4.7.3.5.4.1.1 Amikor az SSNDPX egy kapcsolat létrehozási SNPDU-t vesz a távoli SSNDPX-től, akkor a kiválasztott logikai csatornát a beérkező hívás állapotába kell állítania. Az SSNDPX-nek egy beérkező hívási adatcsomagot kell továbbítania az IWF-hez, alapértelmezési értékeket használva az olyan beállítások esetében, amelyek nem kerülnek továbbításra a műholdas al-hálózaton keresztül (lásd 4.7.3.16 pont).

4.7.3.5.4.1.2 Amikor az SSNDPX egy hívás-fogadási köteget kap az IWF-től, akkor egy kapcsolat megerősítő SNPDU-t kell továbbítania a távoli SSNDPX-nek és a logikai csatornát adat-átviteli/forgalom-vezérlés állapotba (forgalom-vezérlés kész/nincs távoli vagy helyi megszakítás függőben) kell állítania, amikor az illeszkedő adatkapcsolati rétegtől megkapja azt az információt, hogy a kapcsolat megerősítő SNPDU feldolgozásra került (hibázás/siker LIDU).

4.7.3.5.4.2 *Egyéb működés*

4.7.3.5.4.2.1 Ha a vevő SSNDPX nem tudja a kérést támogatni, akkor egy kapcsolat-bontási SNPDU-t kell
továbbítania a kezdeményező SSNDPX-hez.

4.7.3.5.4.2.2 Ha egy kiválasztott beállítási érték nem megengedett, akkor a vevő SSNDPX-nek egy kapcsolat-bontási eljárást kell kezdeményeznie.

4.7.3.6 KAPCSOLAT-BONTÁS

Megjegyzés. – Egy al-hálózati kapcsolatot bármelyik fél bármikor felbonthat, ha a logikai csatorna az adat-átviteli, IWF hívás-kérési, vagy beérkező hívás állapotában van. A kapcsolat bontva SNPDU az IWF által szolgáltatott felhasználói adatokat tartalmazhat (maximum 128 oktett).

4.7.3.6.1 A felhasználói adatokat mindkét irányban átlátható módon kell továbbítani.

4.7.3.6.2 Az SSNDPX-nek garantálnia kell az adatkapcsolati réteghez már továbbított adat/megszakítási SNPDU-k és a rákövetkezőkben továbbított kapcsolat bontva vagy kapcsolat-bontás befejezve SNPDU között a sorrendben történő továbbítást.

4.7.3.6.3 *HELYI KEZDEMÉNYEZÉS*

4.7.3.6.3.1 Amikor az SSNDPX egy bontás kérési adatcsomagot vesz az IWF-től, akkor a logikai csatornát a helyi bontás-kérő állapotba kell állítani, egy kapcsolat bontva SNPDU-t kell előállítania és azt továbbítania kell a távoli SSNDPX-nek. Ezt követően csak a kapcsolat bontva SNPDU-t vagy a kapcsolat-bontás befejezve SNPDU-t fogadhatja. Minden más SNPDU-t érvényteleníteni kell. Az SSNDPX-nek minden nem törlés kérési adatcsomag vételét ugyancsak hibaként kell értékelnie és azt érvényteleníteni kell.

4.7.3.6.3.2 Amikor az SSNDPX egy kapcsolat-bontás befejezve adatcsomagot vesz, miután a kapcsolat-bontás befejezve sikeresen el lett küldve, akkor a logikai csatornát vissza kell állítania a kész állapotba. Ha az SSNDPX egy kapcsolat bontva SNPDU-t vesz a távoli SSNDPX-től, akkor nem kell egy kapcsolat-bontás teljes SNPDU vételére számítania.

4.7.3.6.3.3 Ha az SSNDPX-hez nem érkezik válasz a távoli SSNDPX-től, mielőtt a társított időzítő lejár (lásd tN6, 4-18. táblázat), akkor a logikai csatornát vissza kell állítania a kész állapotba.

4.7.3.6.4 *TÁVOLI KEZDEMÉNYEZÉS*

Amikor az SSNDPX egy kapcsolat bontva SNPDU-t vesz, akkor a távoli bontás kérése állapotba kell lépnie és egy törlés jelzés adatcsomagot kell küldenie az IWF felé. Ugyancsak létre kell hoznia egy kapcsolat-bontás befejezve SNPDU-t, azt el kell küldenie a távoli SSNDPX felé, valamint a logikai csatornát vissza kell állítania a kész állapotba.

4.7.3.6.5 *SSNDPX KEZDEMÉNYEZÉS*

Ha az SSNDPX entitásnak egy kapcsolatot meg kell szakítania, akkor a logikai csatornát a helyi bontás-kérés állapotába kell állítania, egy bontás adatcsomagot kell küldenie az IWF felé, valamint egy kapcsolat-bontási SNPDU-t kell továbbítania a távoli SSNDPX felé. Válaszként egy kapcsolat-bontás befejezve, vagy kapcsolat bontva SNPDU vételére kell várnia a távoli SSNDPX felől, és a logikai csatornát vissza kell állítania a kész állapotba, amikor a várt válasz megérkezik, vagy az időzítési felügyelet lejár (lásd tN6, 4-20. táblázat).

4.7.3.7 ADAT-ÁTVITEL

4.7.3.7.1 Az adat-átviteli eljárást minden olyan logikai csatornára alkalmazni kell, amelyik az adat-átviteli/forgalom-vezérlési állapotban van.

4.7.3.7.2.1 *ADAT-ÁTVITELI ELJÁRÁS*

4.7.3.7.2.1 Az adatokat átláthatóan és sorrendben kell továbbítani az SNS felhasználók között.

4.7.3.7.2.2 Egy M-bites SNPDU sorozatnak egy vagy több adat – SNPDU sorozatból kell állnia. Az utolsó kivételével minden adat – SNPDU-nak tartalmazni kell a felhasználói adatok maximum 503 oktettjét és annak az M-bitjét 1-re kell állítani. A sorozathoz tartozó utolsó SNPDU felhasználói adatmezőjének a hossza rövidebb lehet a maximális hossznál és annak az M-bitjét 0-ra kell állítani.

4.7.3.7.2.3 *Helyi kezdeményezés*

4.7.3.7.2.3.1 Az IWF-től érkezett M-bit adatcsomag sorozatot egy M-bites SNPDU sorozatként kell továbbítani a távoli SSNDPX felé.

4.7.3.7.2.3.2 Egy M-bites adatcsomag sorozathoz tartozó egy vagy több adatcsomagnak az IWF-től történő vétele esetén az SSNDPX-nek elő kell állítania egy vagy több adat-SNPDU-t az M-bitet felhasználva az azonos sorozat következő adat – SNPDU-jainak jelzésére, és azokat továbbítania kell a távoli SSNDPX részére.

Megjegyzés. – A sorozatban szükséges adat-SNPDU-k száma az M-bites adatcsomag sorozathoz tartozó adatcsomagokban lévő felhasználói adatok mennyiségétől függ.

4.7.3.7.2.3.3 Az SSNDPX-nek minden adat-SNPDU-hoz ugyancsak ki kell jelölnie egy SNPDU számot. Egy adott kapcsolat viszonylatában az SNPDU számoknak egymásra következőknek kell lenniük. Az adat-SNPDU-k sorozatszámozását moduló 256-tal kell elvégezni és az SNPDU számoknak a 0-tól 255-ig terjedő teljes tartományban kell ciklikusan változniuk. A műholdas összeköttetésen elsőként küldendő adat-SNPDU SNPDU számának nullával kell egyenlőnek lenni, amikor a logikai csatorna éppen belép a forgalom-vezérlésre kész állapotba.

4.7.3.7.2.4 *Távoli kezdeményezés*

4.7.3.7.2.4.1 A távoli SSNDPX-től érkezett M-bites SNPDU sorozatot egy M-bites csomag sorozatként kell az IWF részére továbbítani.

4.7.3.7.2.4.2 Egy M-bites SNPDU sorozat vételekor az SSNDPX-nek egy M-bites csomag sorozatot kell előállítania, az M-bitet az ugyanazon sorozat következő csomagjának jelzésére felhasználva, ahogy szükséges, és azt továbbítania kell az IWF felé.

Megjegyzés. – Az M-bites csxomag sorozatban lévő adatcsomagok száma az M-bites SNPDU sorozatban lévő felhasználói adatok mennyiségétől és a csomag méretétől függ.

4.7.3.7.2.4.3 Ha egy olyan adat-SNPDU érkezik, amely a maximális méretnél kisebb és az M-bitje = 1, valamint a D-bit = 0, akkor az SSNDPX-nek egy visszaállítási eljárást kell kezdeményeznie (lásd 4.7.3.8.2.1 pont).

4.7.3.7.3 *FORGALOM-VEZÉRLÉS*

4.7.3.7.3.1 Az SSNDPX-en belül forgalom-vezérlést kell alkalmazni az adat-tárolók túlcsordulásának megelőzése érdekében.

4.7.3.7.3.2 Az adatok áramlásának megszakítására a vevő SSNDPX-nek egy olyan forgalom-vezérlési SNPDU-t kell előállítania, amelynek az forgalom-vezérlési ok mezője a felfüggesztésére és a távoli SSNDPX-hez való továbbítására van beállítva. A forgalom-vezérlési (felfüggesztési) SNPDU-ban az SNPDU számát az utoljára vett és fogadott adat-SNPDU SNPDU számára kell beállítani. Ha van sorozaton kívüli adat-SNPDU az SSNDPG-ben, akkor az ok mezőjében felfüggesztésre beállított forgalom-vezérlési SNPDU-ban lévő SNDPU számot a sorozaton kívüli SNPDU előtt vett és elfogadott SNPDU-nak az SNPDU számára kell beállítani. Amikor ezt követően a vevő SNDPX képes az adat-átvitel folytatására, akkor a forgalom-vezérlési ok mezőjében folytatásra beállított forgalom-vezérlési SNPDU-t kell továbbítania.

4.7.3.7.3.3 Amikor az SSNDPX egy olyan forgalom-vezérlési SNPDU-t vesz, amelynek a forgalom-vezérlési mezője felfüggesztésre van beállítva, akkor abba kell hagynia az adat-SNPDU-k továbbítását a jelzett logikai csatornán. Ha a forgalom-vezérlési (felfüggesztési) SNPDU-ban lévő SNPDU-szám különbözik az utolsóként továbbított adat-SNPDU számától és az az adat-SNPDU, amelynek az SNPDU száma egyenlő a forgalom-vezérlési (felfüggesztési) SNPDU plusz egy moduló 256 nincs már az adat-tárolóban, akkor az SSNDPX-nek logikai csatorna visszaállítását kell kezdeményeznie. Amikor az SSNDPX egy olyan forgalom-vezérlési SNPDU-t vesz, amelynek az ellenőrző mezője folytatásra van beállítva, akkor újból el kell kezdenie az adat-SNPDU-k továbbítását a jelzett logikai csatornán. Az első (újra) továbbított adat-SNPDU SNPDU-számának egyenlőnek kell lenni a korábban vett forgalom-vezérlési (felfüggesztési) SNPDU plusz egy moduló 256 SNPDU számával, amennyiben visszaállítási eljárást nem kezdeményeztek.

4.7.3.7.3.4 Ha a vevő SSNDPX nem képes az adat-átvitel folytatására, mielőtt a társított időzítő lejár (lásd tN7, 4-18. és 4-20. táblázatok), akkor a logikai csatorna visszaállítását kell kezdeményeznie.

4.7.3.7.4 *GYORSÍTOTT ADAT-ÁTVITEL*

Megjegyzés. – A gyorsított adat-átvitel lehetővé teszi egy SSNDPX számára azt, hogy egy megszakítás csomagban lévő felhasználói adatot a távoli SSNDPX-nek továbbítson, megkerülve bármely olyan forgalom-vezérlést, amelyet az al-hálózati réteg entitás alkalmazhatott volna.

4.7.3.7.4.1 A gyorsított adat-átviteli eljárás függetlenül alkalmazható az egyes logikai csatornákra, amelyek adat-átvitel állapotban vannak, és nem kezdeményezhető akkor, amikor egy bontási vagy visszaállítási eljárás van folyamatban.

4.7.3.7.4.2 Egyidőben mindegyik irányban csak egy, 32 oktett felhasználói adat hosszúságú SNPDU megszakítás engedélyezhető.

4.7.3.7.4.3 *Helyi kezdeményezés*
4.7.3.7.4.3.1 Amikor a kezdeményező SSNDPX megszakítás csomagot vesz az IWF-től és feltételezve, hogy nincs előző megszakítási SNPDU, amely megszakítás-megerősítés SNPDU-ra vár, akkor az SSNDPX-nek egy megszakítás SNPDU-t kell generálnia és továbbítani a távoli SSNDPX-nek, és várni egy megszakítás-megerősítő SNPDU-ra; egyébként az SSNDPX-nek a megszakítás csomagot ki kell selejteznie.

4.7.3.7.4.3.2 Egy megszakítás-megerősítő SNDPU vétele után az SSNDPX-nek létre kell hoznia egy megszakítás-megerősítés csomagot és azt továbbítania kell az IWF-hez.

4.7.3.7.4.3.3 Ha az SSNDPX nem veszi a megszakítás-megerősítés SNDPU-t mielőtt a hozzátartozó időzítő (lásd tN4 a 4-18. táblázatban és a 4-20. táblázatban) lejár, akkor a logikai csatorna visszaállítását kell kezdeményeznie.

4.7.3.7.4.4 *Távoli kezdeményezés*

4.7.3.7.4.4.1 Amikor az SSNDPX egy megszakítási SNPDU-t vesz, akkor egy megszakítási csomagot kell továbbítania az IWF-hez.

4.7.3.7.4.4.2 Amikor az SSNDPX egy megszakítás-megerősítő csomagot vesz az IWF-től, akkor létre kell hoznia egy megszakítás-megerősítő SNPDU-t és azt el kell küldenie a távoli SSNPDX-nek.

4.7.3.8 KAPCSOLAT VISSZAÁLLÍTÁS

4.7.3.8.1 Amikor az SSNDPX hibát érzékel annak az SSNDPX-nek a működésében, amelynek részére vissza kell állítani a virtuális áramkört (lásd 4-24. táblázat), akkor a logikai csatornát a helyi visszaállítási állapotba kell állítania, végre kell hajtania a visszaállítás eljárást és egy visszaállítás SNPDU-t kell küldenie a távoli SSNDPX felé.

Megjegyzés. – Az ok és hibamegállapító kódok jelzik, hogy a visszaállítást csak a műholdas al-hálózaton belül kell-e végrehajtani, vagy azt ki kell-e terjeszteni az IWF-re is.

4.7.3.8.2 *VISSSZAÁLLÍTÁSI TEVÉKENYSÉG*

A visszaállítási eljárás ideje alatt az SSNDPX által a következő tevékenységet kell végrehajtani, tekintettel az adat-átviteli működésére:

a) azokat az SNPDU-kat, amelyek még nem kerültek továbbításra az adatkapcsolati réteghez, érvényteleníteni kell;
b) azokat az SNPDU-kat, amelyek vételére egy visszaállítás SNPDU vétele/adása előtt került sor, de nem képeznek egy M-bites SNPDU sorozatot, ki kell üríteni az újra- összeállítási területről;
c) a várható (adat) SNPDU-számot 0-ra kell visszaállítani és az azt követően továbbított adat SNPDU-kat 0-tól kezdődően kell számozni; és
d) a bármely nem odatartozó megszakítási SNPDU-knak a távoli SSNDPX-hez vagy -tól megerősítés nélkül kell maradniuk, és a tN4-et meg kell állítani.

4.7.3.8.3 *VISSZAÁLLÍTÁSI ELJÁRÁSOK*

4.7.3.8.3.1 A vissszaállítási eljárásokat csak az adat-átviteli állapotban lévő logikai csatornákra kell alkalmazni.

4.7.3.8.3.2 Az SSNDPX-nek garantálnia kell a már az adatkapcsolati réteghez továbbított adat/megszakítási SNPDU-k és a rákövetkezőkben küldött visszaállítás vagy visszaállítás- megerősítő SNPDU között a sorrendben való továbbítást.

4.7.3.8.3.3 *Helyi/SSNDPX kezdeményezés*
4.7.3.8.3.3.1 Amikor a kezdeményező SSNDPX egy visszaállítás kérő csomagot vesz az IWF-től, vagy egy olyan hibát érzékelt, amikor vissza kell állítania az SVC-t, akkor a logikai csatornát a helyi visszaállítás állapotba kell állítania, végre kell hajtania a vissza- állítási akciót, egy új visszaállítás SNPDU-t kell küldenie a távoli SSNDPX-hez, és el kell indítania egy tN3 időzítőt (lásd 4-18. táblázat). Ha a 4.7.3.9 pont alatti hibajavító eljárások megkövetelik, akkor az SSNDPX-nek egy visszaállítás jelző csomagot kell továbbítania az IWF-nek.

4.7.3.8.3.3.2 A visszaállítás-megerősítő SNPDU távoli SSNDPX-től való vételekor vissza kell állítania a logikai csatornát az adat-átviteli/forgalom-vezérlésii állapotba.

4.7.3.8.3.3.3 Ha az SSNDPX nem kap választ az SSNDPX-től mielőtt a hozzátartozó időzítő lejár (lásd tN3, 4-18. táblázat), akkor egy kapcsolat-bontó eljárást kell kezdeményeznie.

4.7.3.8.3.4 *Távoli kezdeményezés*

4.7.3.8.3.4.1 Amikor az SSNDPX egy visszaállítás SNPDU-t vesz, akkor a logikai csatornát a távoli visszaállítási állapotba kell állítania, végre kell hajtania az visszaállítási akciót és egy visszaállítás-jelző csomagot kell küldenie az IWF-nek, a követelmények szerint (lásd 4-24. táblázat).

4.7.3.8.3.4.2 Az SSNDPX-nek egy visszaállítás-megerősítő SNPDU-t kell küldenie a távoli SSNDPX részére és a logikai csatornát az adat-átviteli állapotba kell visszaállítania, amikor megkapja az adatkapcsolati rétegtől azt az információt, hogy az visszaállítás- megerősítő SNPDU sikeresen továbbításra került.

4.7.3.8.3.5 *Egyidejű visszaállítás*

Ha az SSNDPX egy visszaállítás SNPDU-t küld és azt követően egy visszaállítás SNPDU-t vesz, akkor:

a) nem küldhet egy visszaállítás-megerősítő SNDPU-t; és

b) nem számíthat egy visszaállítás-megerősítő SNPDU vételére.

4.7.3.9 HIBA ELJÁRÁSOK

Megjegyzés. – Az SSNDPX által felismert hibákat a következő események eredményezhetik:

– csatorna teljesítőképesség-csökkenés vagy a szinkronzáció elvesztése;
– AES kijelentkezés;

– GES és GES közötti átadás;

– kapcsolati torlódás;

– egy kijavítatlan átviteli hiba;

– egy távoli SSNDPX protokol-hiba;

– egy protokol-hiba az IWF/SSNDPX interfész eljárásban.

4.7.3.9.1 Amikor a 4-22. – 4-24. táblázatokban leírt hibát érzékelnek, akkor az SSNDPX-nek a vonatkozó kapcsolat visszaállítását, vagy bontását kell kezdeményeznie.

4.7.3.9.2 Az IWF-et a hibákról a vonatkozó csomagban lévő ok és hibakereső paraméterek segítségével kell értesíteni. A távoli SSNDPX-et az SNPDU-k megfelelő mezőinek használatával kell értesíteni, úgy mint: visszaállítás vagy bontási ok és hibakereső kód.

4.7.3.9.3 Az SSNDPX által előállított és a távoli SSNDPX-nek továbbított ok mezők kódolásának meg kell felelni a 4-16. táblázatban foglaltaknak.

4.7.3.9.4 A megfelelő SSNDPX által létrehozott hibakereső kódmező kódolásának meg kell felelni a 4-17. táblázatban foglaltaknak.

4.7.3.9.5 *BEJELENTKEZÉS/KIJELENTKEZÉS*

Megjegyzés. – A bejelentkezés és a kijelentkezés eljárásait a 4.7.6 pont tartalmazza.

4.7.3.9.6 *KEZDEMÉNYEZŐ SSNDPX HIBAJAVÍTÁS*

4.7.3.9.6.1 Az SSNPDU-k elvesztéséből vagy késéséből származó adás-hibákat akkor, amikor egy választ várnak, vagy a lejárati idővel, vagy az adatkapcsolati réteg által jelentett hiba LIDU-val kell észlelni.

4.7.3.9.6.2 Lejárt idő esetén az SSNDPX által követendő tevékenységeket a 4-18. táblázat ismerteti.

4.7.3.9.6.3 Az adatkapcsolati réteg általi, SNPDU továbbítási hiábról szóló tájékoztatás esetén az SSNDPX által követendő tevékenységeket a 4-19. táblázat ismerteti. Egy LIDU hiba (adat/megszakítás) vétele, miközben a vonatkozó LCN akár helyi/távoli újraállítás, akár helyi/távoli bontás-kérő állapotban van, nem késztetheti az SSNSD al-hálózati entitást egy (további) kapcsolati visszaállítás létrehozására.

4.7.3.9.7 *PROTOKOL-HIBA*

Megjegyzés. – A protokol-hibák két típusa fordulhat elő az SSNDPX-nél. Ezek a következők:

a) szintaktikai hiba, ami akkor fordul elő, ha a vett SNPDU nem felel meg a műholdas al-hálózati formai követelményeknek; és

b) logikai hiba, ami akkor fordul elő, ha az SSNDPX a társ-entitásától egy olyan SNPDU-t vesz, ami a logikai csatorna pillanatnyi állapota szerint nem fogadható el adat-bevitelként.

4.7.3.9.7.1 Amikor az SSNDPX egy protokol-hibát érzékel, a 4-21. - 4-24. táblázatokban foglaltak szerint kell válaszolnia. Ezeket a táblázatokat minden logikai csatorna állapothoz elkészítették.

4.7.3.9.8 *SORRENDEN KÍVÜLI ADAT-SNPDU ELJÁRÁS*

4.7.3.9.8.1 Az SSNDPX-nek a vett adat-SNPDU-kat az SNPDU-számának megfelelő sorrendben kell feldolgoznia az IWF felé továbbítandó adatcsomagok létrehozása céljából. Az SSNDPX-nek a duplikált SNPDU-kat érvénytelenítenie kell.

Megjegyzés. – A GES-nél a vevő adatkapcsolati réteg az SSNDPG részére az SNPDU-kat váltott sorrendben is továbbíthatja. Az SSNDPG megfelelő sorrendbe rendezi az adat-SNPDU-kat, mielőtt az IWF-nek elküldi azokat.

4.7.3.9.8.2 *SSNDPG tevékenységek sorrenden kívüli adat-SNPDU-k esetében:*

Egy adat-SNPDU-t akkor és csak akkor kell sorrenden kívülinek meghatáározni, ha az SNPDU-száma nem azonnal következik az utolsó adatcsomag létrehozásában használt utolsóként vett adat-SNPDU SNPDU-száma után.
Megjegyzés. – Az SNPD-számok moduló 256 alapján növekednek. Így, a 255-ös SNPDU-számot a 0 SNPDU-szám követi.

4.7.3.9.8.2.1 Ha egy sorrenden kívüli adat-SNPDU nem duplikált, akkor az SSNSDPG-nek tárolnia kell a sorrenden kívüli adat-SNPDU-t. Ha már nem áll rendelkezésre több tárolóhely, akkor az SSNDPG-nek a logikai csatornát visszaállítás állapotba kell helyeznie, és a visszaállítást ki kell terjesztenie az IWF-re is.

4.7.3.9.8.2.2 A tárolt adat-SNPDU-kat fel kell dolgozni adatcsomagok létrehozása céljából, amikor az megtehető egy sorrenden kívüli feltétel létrehozása nélkül. Az adatcsomagokat - amint lehetséges - továbbítani kell az IWF részére.

4.7.3.9.8.3 *SSNDPA tevékenységek sorrenden kívüli SNPDU-k esetében.*

Ha egy nem duplikált, de az utoljára vett adat-SNPDU SNPDU-számát nem azonnal követő adat-SNPDU kerül vételre, akkor az SSNDPA-nak a kapcsolat visszaállítását kell kezdeményeznie.

4.7.3.10 AL-HÁLÓZATI PROTOKOL ADAT-EGYSÉG /SNPDU/ FORMÁTUMOK

4.7.3.10.1 *ÁLTALÁNOS SNPDU FORMÁTUM*

4.7.3.10.1.1 Egy SNPDU-nak legalább két oktettből kell állnia. Az 1. számú oktettnek kell tartalmaznia a
D- és M-biteket, valamint az SNPDU típus azonosító mezőt. A 2. számú oktettnek kell tartalmazni a logikai csatorna-szám mezőt; az adott SNDPU típusától függően további oktettek is megkövetelhetők. Az általános SNPDU formátumnak a 4-13. ábra szerint meghyatározottnak kell lennie.

4.7.3.10.1.2 A D-bitnek az 1. számú oktett 7., az M-bitnek az 1. számú oktett 8. bitjének kell lennie.

4.7.3.10.1.3 Az M-bitet egy adat-SNPDU sorozatból álló M-bit SNPDU sorozatban kell alkalmazni; minden más SNPDU-ban 0-ra kell állítani.

Megjegyzés. – A D-bit a végberendezés - végbrendezés közötti nyugtázásra használható (a vétel megerősítése).

4.7.3.10.1.4 Az SNPDU típus-azonosító mezőnek az 1. számú oktett 1-6 bitjeinek kell lenni. Az SNPDU típus-azonosító mező kódolásának a 4-15. táblázatban megadottaknak megfelelőnek kell lenni.

4.7.3.10.1.5 A 2. számú oktettnek kell tartalmaznia a logikai csatorna-szám mezőt.

Megjegyzés. – A következő részekben a mezők meghatározása a vonatkozó SNPDU-ban való megjelenhetésük sorrendje alapján történt.

4.7.3.10.2 *KAPCSOLAT-KÉRÉSI SNPDU*

4.7.3.10.2.1 A kapcsolat-kérési SNPDU formátumának a 4-14. ábrán meghatározottaknak megfelelőnek kell lennie.

4.7.3.10.2.2 *SNDPU típus-azonosító mező*

4.7.3.10.2.2.1 Az 1., 2., 3. és 6. biteknek a következő jelző biteknek kell lenniük:

a) 1. bit, szolgáltatási mező jelen van;

b) 2. bit, a hívott NSAP cím jelen van;
c) 3. bit, a hívó NSAP cím jelen van; és

d) 6. bit, gyors kiválasztás válasz-korlátozással.

4.7.3.10.2.2.2 Az 1., 2. és 3. bitet 1-re kell állítani, ha a megfelelő mezők jelen vannak a kapcsolat-kérési SNPDU-ban; máskülönben 0-ra kell azokat állítani. A 6. bitet 1-re kell állítani a gyors kiválasztás válasz-korlátozás alkalmazása esetén; máskülönben 0-ra kell állítani.

4.7.3.10.2.3 *DTE cím-hossz mező*

A 3. oktettnek a hívó és hívott DTE cím-hossz mezőkből kell állni. A 8-tól 5-ig terjedő biteknek kell meghatározniuk a hívó DTE cím hosszát fél-oktettekben. A 4-től 1-ig terjedő biteknek kell meghatározniuk a hívott DTE cím hosszát fél-oktettekben. Minden cím-hossz mezőnek binárisan kódoltnak kell lenni, ahol az 5. vagy 1. bitnek a jelző bitek alsacsonyabb érékű bitjének kell lenni.

4.7.3.10.2.4 *A hívó- és a hívott DTE mezők*

4.7.3.10.2.4.1 Amikor a DTE cím-hossz mezők jelzik, a DTE cím-hossz mezőt követő oktetteknek tartalmaznia kell a hívott DTE címet, amit a hívó DTE cím követ.

4.7.3.10.2.4.2 Egy cím minden számjegyét egy fél-oktettben Binárisan Kódolt Decimális formában kell kódolni, ahol az 5. vagy az 1. bitnek kell a számjegyek alacsonyabb értékű bitjének kell lenni.

4.7.3.10.2.4.3 A magasabb értékű számjegytől kezdve a DTE címet egymást követő oktettekben kell kódolni, oktettenként két számjeggyel. Minden oktettben a magasabb értékű számjegyet a 8.-tól az 5.-ig terjedő bitekben kell kódolni. Amikor a hívott plusz hívó DTE mezőkben lévő számjegyek teljes száma páratlan, a kombinált mezőket a kombinált mezők utolsó oktettjeinek 4.-től 1.-ig terjedő bitjeiben 0 értékek beállításával fel kell kerekíteni egy integrált oktett-számra.

4.7.3.10.2.5 *Hívott és a hívó Hálózati réteg szolgálat elérési pont /NSAP/ cím mezők*

Amikor a hívott és a hívó NSAP cím 'jelen van' jelző bitek jelzik, akkor a hívó és a hívott DTE mezőket követő oktetteknek tartalmazniuk kell a hívott NSAP cím mezőt, majd a hívó NSAP cím mezőt.

4.7.3.10.2.6 *Szolgáltatási mező hossz*

Amikor a szolgáltatási mező hossz 'jelen van' jelzőbit jelzi, akkor a következő oktettnek a szolgáltatási mező hosszát oktettekben kell tartalmaznia. A szolgáltatási mező hosszmezőt binárisan kell kódolni, ahol az 1. bitnek a mező alacsonyabb értékű bitjének kell lenni.

4.7.3.10.2.7 *Szolgáltatási mező*

Amikor a szolgáltatási mező 'jelen van' jelzőbit jelzi, akkor a szolgáltatási mező hosszmezőt követő oktetteknek kell tartalmazniuk a szolgáltatások kódjait és paramétereit.

4.7.3.10.2.8 *Hívás felhasználói adat mező*

A következő oktetteket kell a hívó felhasználói adatok szállítására használni, ha ilyenek vannak. Ha a gyors kiválasztás szolgáltatást nem használják, akkor nem több, mint 16 oktettnyi adatnak kell jelen lenni. Ha a gyors kiválasztási szolgáltatást használják, akkor nem több, mint 128 oktettnyi adatnak kell jelen lenni.

4.7.3.10.3 *KAPCSOLAT MEGERŐSÍTŐ SNPDU*

4.7.3.10.3.1 A kapcsolat megerősítő SNPDU formátumának a 4-15. ábrán meg- határozottnak kell lenni.
4.7.3.10.3.2 *SNPDU típus-azonosító mező*

4.7.3.10.3.2.1 Az 1. és 2. számú biteknek a következő jelző biteknek kell lenniük:

a) 1. bit: szolgáltatási mező 'jelen van'; és

b) 2. bit: NSAP cím 'jelen van'.

4.7.3.10.3.2.2 Ezeket a biteket 1-re kell állítani, ha a megfelelő mezők jelen vannak; ellenkező esetben 0-ra kell állítani.

4.7.3.10.3.3 *Hívott NSAP cím mező*

Amikor az NSAP cím 'jelen van' jelző bit jelzi, a logikai csatorna-szám mezőt követő oktetteknek a hívott NSAP címből kell állniuk.

4.7.3.10.3.4 *Szolgáltatási hossz mező*

Amikor a szolgáltatási mező 'jelen van' jelző bit jelzi, akkor a következő oktettnek a szolgáltatási mező hosszát oktettekben kell tartalmaznia. A szolgáltatási hossz jelzőnek binárisan kódoltnak kell lennie, ahol az 1. bitnek kell a mező alacsonyabb értékű bitjének lenni.

4.7.3.10.3.5 *Szolgáltatási mező*

Amikor a szolgáltatási mező 'jelen van' jelző bit jelzi, a szolgáltatási mezőt követő oktetteknek kell tartalmazniuk a szolgáltatások kódjait és paramétereit.

4.7.3.10.3.6 *A hívott felhasználói adat mező*

A következő oktetteket kell a hívott felhasználói adatok továbbítására használni, ha vannak ilyenek. Ha a gyors kiválasztás értéket használják, akkor nem több, mint 128 oktettnyi adatnak kell jelen lenni.

4.7.3.10.4 KAPCSOLAT BONTVA SNPDU

4.7.3.10.4.1 A kapcsolat bontva SNPDU formátumnak a 4-16. ábrán megadottaknak megfelelőnek kell lenni.

4.7.3.10.4.2 *SNPDU típus-azonosító mező*

4.7.3.10.4.2.1 A 2. bitnek kell az NSAP cím 'jelen van' jelző bitnek lenni.

4.7.3.10.4.2.2 Ezt a bitet 1-re kell állítani, ha a hívott NSAP cím mező jelen van; egyébként 0-ra.

4.7.3.10.4.3 *Hívott NSAP cím mező*

Ennek a mezőnek a 4.7.3.10.3.3 pont alatti kódolássall megegyező kódolásúnak kell lenni.

4.7.3.10.4.4 *A törlést létrehozó ok mező*

4.7.3.10.4.4.1 A következő oktettnek kell a törlést létrehozó ok mezőnek lenni. Tartalmaznia kell a kapcsolat bontását létrehozó törlési okot.

4.7.3.10.4.4.2 Az SSNDPX által létrehozható törlést létrehozó mező kódolásának a 4-16. táblázatban megadottak szerintinek kell lenni.

4.7.3.10.4.5 *Hibakereső kód mező*

A törlést létrehozó mezőt követő oktettnek kell a hibakereső kód mezőnek lenni. Kiegészítő információt kell tartalmaznia a kapcsolat bontásának okát illetően. A hibakereső kód mező kódolásának a 4-16. táblázatban található törlés kiváltó októl kell függenie. A hibakerső kód mező kódolásának az SSNDPX által kezdeményezett kapcsolat-bontás esetén a 4-17. táblázatban meghatározottak szerintinek kell lenni.

4.7.3.10.4.6 *Törlés felhasználói adat mező*

A hibakereső kód mezőnek a felhasználói adat mezőnek kell lenni. Ha 'jelen van', akkor nem több, mint 128 oktettnyi felhasználói adatot kell tartalmaznia.

4.7.3.10.5 *A KAPCSOLAT-BONTÁS BEFEJEZVE SNPDU*

A kapcsolat-bontás befejezve SNPDU formátumnak a 4-17. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.6 *ADAT SNPDU*

4.7.3.10.6.1 Az adat SNDPU formátumnak a 4-18. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.6.2 *M-bit*

Az M-bitet 1-re kell állítani, ha az SNPDU nem az utolsó az adat-SNPDU M-bit sorozatában; máskülönben 0-ra kell állítani.

4.7.3.10.6.3 *SNPDU-szám mező*

A 3. oktettnek kell tartalmaznia a 8 bites SNPDU-számot.

4.7.3.10.6.4 *Felhasználói adat mező*

Az SNPDU-szám mezőt követő mezőnek kell tartalmaznia a felhasználói adatokat. Ez a mező maximálisan 503 oktettet tartalmazhat.

4.7.3.10.7 *MEGSZAKÍTÁSI ADAT SNPDU*

4.7.3.10.7.1 A megszakítási adat SNPDU-nak a 4-19. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.7.2 *Megszakítási felhasználói adat mező*

A logikai csatorna-szám mezőt követő mezőnek kell a megszakítási felhasználi adat mezőnek lenni. Ez a mező maximálisan 32 oktettet tartalmazhat.

4.7.3.10.8 *MEGSZAKÍTÁS-MEGERŐSÍTŐ SNPDU*

A megszakítás-megerősítő SNPDU formátumnak a 4-20. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.9 *VISSZAÁLLÍTÁS SNPDU*

4.7.3.20.9.1 A visszaállítás SNPDU formátumnak a 4-21. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.9.2 *A visszaállítást kiváltó ok*

A 3. oktettnek kell a visszaállítást kiváltó ok mezőnek lenni és tartalmaznia kell a visszaállítás kiváltó okát. Amikor a visszaállítást az SSNDPX kezdeményezi, akkor a visszaállítási SNPDU-ban lévő visszaállítást kiváltó ok mező kódolásának a 4-16. táblázat- ban megadottak szerintinek kell lenni.

4.7.3.10.9.3 *Hibakereső kód*

4.7.3.10.9.3.1 A 4. oktettnek kell a hibakereső kód mezőnek lenni és további információkat kell tartalmaznia a visszaállítást kiváltó okról. A hibakereső kód mező kódolásának a 4-16. táblázatban megadott visszaállítást kiváltó októl kell függenie. A hibakerső kód mező kódolásának, amikor az SSNDPX kezdeményezi a visszaállítást, a 4-17. táblázatban megadottak szerintinek kell lenni.

4.7.3.10.9.3.2 Ha a visszaállítás mező “IWF kezdeményezés”-t jelez, akkor a hibakereső kód mezőt változtatás nélkül kell továbbítani az IWF felől annak eredményeképpen, hogy az már egy vissszaállítási eljárást kezdeményezett.

4.7.3.10.10 *VISSZAÁLLÍTÁS-MEGERŐSÍTŐ SNPDU*

A visszaállítás-megerősítő SNPDU formátumának a 4-22. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.11 *FORGALOM-VEZÉRLŐ (FELFÜGGESZT) SNPDU*

4.7.3.10.11.1 A forgalom-vezérlő (felfüggeszt) SNPDU formátumnak a 4-23. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.11.2 *Forgalom-vezérlés ok mező*

A 3. oktettnek kell tartalmaznia a forgalom-vezérlés ok mezőt. Ezt a mezőt 11001001-re (felfüggeszt) kell állítani.

4.7.3.10.11.3 *SNPDU-szám mező*

A 4. oktettnek kell tartalmaznia a sorrendben utolsóként vett és elfogadott adat-SNDPU 8-bites SNPDU-számát.

4.7.3.10.12 *FORGALOM-VEZÉRLÉS OK (ÚJRA KEZD) SNPDU*

4.7.3.10.12.1 A forgalom-vezérlés (újra kezd) SNPDU formátumnak a 4-24. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.12.2 *Forgalom-vezérlés mező*
A 3. oktettnek kell tartalmaznia a forgalom-vezérlés ok mezőt. Ezt a mezőt 11001011-re (újra kezd) kell állítani a társ-állomástól való továbbítás folytatására.

4.7.3.10.13 *KAPCSOLAT- KÉRÉS/MEGERŐSÍTÉS SNPDU SZOLGÁLTATÁS MEZŐK*

4.7.3.10.13.1 A szolgáltatás mezőnek csak akkor kell jelen lenni, amikor a szolgáltatás mező 'jelen van', jelző bitje pedig egyre van állítva a kapcsolat-kérésben és a kapcsolat- megerősítő SNPDU-ban.

4.7.3.10.13.2 A szolgáltatás mezőnek minden megkívánt szolgáltatáshoz vagy szolgáltatás-csoporthoz egy beállítási elemet kell tartalmaznia. Minden szolgáltatási elem első oktettjének annak a szolgáltatási mezőnek kell lenni, amelynek jeleznie kell a megkívánt szolgáltatás vagy szolgáltatás-csoport kódját. A szolgáltatási elem fennmaradó oktettjeinek kell tartalmaznia a szolgáltatási paraméter-mezőt.

4.7.3.10.13.3 *Ajánlott szolgáltatások*
Ajánlás. – *Az SSNDPX-nek a következő szolgáltatásokat kell alátámasztania:*

a) áteresztő teljesítmény szerinti osztály egyeztetés

b) a továbíbtás késés kiválasztása és jelzése; és

c) gyors kiválasztás.

4.7.3.10.13.4 *Áteresztő teljesítmény szerinti osztály egyeztetés (TCN) szolgáltatás formátuma.*

Az áteresztő teljesítmény szerinti osztály egyeztetés (TCN) szolgáltatás formátumának a 4-25. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.13.5 *Továbbítási késés kiválasztás és jelzés (TDSAI) szolgáltatás formátuma.*
A továbbítási késés kiválasztás és jelzés szolgáltatás mező formátumának a 4-26. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.13.6 *Gyors kiválasztás szolgáltatás mező formátum*

A gyors kiválasztás szolgáltatás mező formátumának a 4-27. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.13.7 *Gyorsított adategyeztetés*

A gyorsított adategyeztetés szolgáltatás formátumának a 4-28. ábrán meghatározottak szerintinek kell lenni.

4.7.3.10.14 *HIBAKERESŐ KÓDOK*

Amikor az SSNDPX megszakítást/visszaállítást kezdeményez, akkor a kapcsolat bontva és visszaállítva SNDPU-kban lévő hibakeereső kód mező kódolásának a 4-17. táblázatban meghatározottak szerintinek kell lenni.

4.7.3.11 IDŐZÍTÉSI ÉRTÉKEK

Az időzítési értékeknek a 4-20. táblázatban meghatározottak szerintinek kell lenniük.

4.7.3.12 ÁLLAPOT-DIAGRAMMOK

A következő állapotok állapot-diagrammjait az alábbiak szerint kell megadni:

a) A logikai csatorna kapcsolat létrehozás/megszakítás állapot-diagramnak a 4-29. ábrán meghatározottak
szerintinek kell lenni.

b) A visszaállítási és forgalom-vezérlési állapot-diagramnak a 4-30. ábrán meghatározottak szerintinek kell
lenni.

4.7.3.13 ÁLLAPOT-TÁBLÁZATOK

4.7.3.13.1 Az SSNDPX bármely állapotában végzett tevékenységnek a 4-21 – 4-24. táblázatok által megadottnak kell lenni.

4.7.3.13.2 Az állapot-táblázatokban a következő konvenciókat kell alkalmazni:

a) végzett cselekmény, ami lehet:

– szabvány, amint azt a 4.7.3.5 – 4.7.3.8 pontok meghatározzák;

– a vett SNPDU érvénytelenítése és ezt követően nincs esemény az SNPDU vételének eredményeként;

– hiba, a táblázatban meghatározott módon;

b) D = a jelzett hiba észlelésekor kibocsátott megfelelő SNPDU (kapcsolat megszakítva, vagy visszaállítva) hibakereső kód mezőjében lévő hibakereső kód.

4.7.3.14 ADATKAPCSOLATI INTERFÉSZ FUNKCIÓKTÓL FÜGGŐ MŰHOLDAS AL-HÁLÓZAT

4.7.3.14.1 Az adatkapcsolati réteghez kapcsolódó interfész funkcióknak a következőket kell tartalmazniuk:

a) adatkapcsolati réteg adat egységek (LIDU-k) előállítása és vétele;

b) vett SNPDU-k kapcsolatnak megfelelő útvonal kiválasztása;

c) további SNPDU-k továbbításra történő kiválasztása adott Q számmal rendelkező logikai csatornák közötti ciklikus rend szerinti kiválasztáshoz és az elsőbbség biztosítása megszakítási SNPDU-k számára az ugyanazon Q számmal rendelkező adat-SNPDU-kkal szemben; és

d) helyi nyugtázás (siker/hiba) útvonal kiválasztása az RLS adás állapot-jelző LIDU-k számára.

4.7.3.14.2 Az SSNDPX és az adatkapcsolati réteg között továbbított LIDU-(k)nak tartalmazni kell a 4-25. táblázatban meghatározott LIDU-kat.

4.7.3.15 A CSOMAGNAK AZ SNPDU-BA VALÓ LEKÉPEZÉSI SZABÁLYAI

4.7.3.15.1 Az ISO 8208 csomag mezőknek az SNPDU megfelelő mezőibe történő leképezési szabályainak az ebben a részben meghatározottak szerintinek kell lenniük.

4.7.3.15.2 *DTE CÍMEK*

4.7.3.15.2.1 A kapcsolat-kérő SNPDU-ban az ISO 8208 hívás-kérő csomagban lévő hívott DTE címet és a hívó DTE cím mezőt közvetlenül le kell képezni a hívott DTE címbe és a hívó DTE cím mezőkbe.

4.73.15.2.2 Az ISO 8208 hívás elfogadva csomagban a hívó és a hívott DTE címeket nem szabad a műholdas kapcsolaton keresztül továbbítani.

4.7.3.15.3 *HÁLÓZATI RÉTEG SZOLGÁLAT ELÉRÉSI PONT /NSAP/ CÍM*

4.7.3.15.3.1 A kapcsolatkérő SNPDU-ban az ISO 8208 híváskérő csomag hívott cím kiterjesztési és hívó cím kiterjesztési paraméter-mezőit közvetlenül le kell képezni a hívott NSAP címbe és a hívó NSAP cím mezőkbe.

4.7.3.15.3.2 Ha az ISO 8208 hívás elfogadva vagy törlés-kérő csomagban lévő hívott cím kiterjesztésű paraméter egyenlő a megfelelő kapcsolat-kérő SNDPU hívott NSAP címével, akkor a hívott cím kiterjesztést nem szabad a műholdas kapcsolaton keresztül továbbítani; ellenkező esetben közvetlenül le kell képezni a vonatkozó SNPDU-ba.

4.7.3.15.4. *AL-HÁLÓZATI KAPCSOLATI ELSŐBBSÉG*

4.7.3.15.4.1 Az ISO 8208 hívás-kérő csomagban egy kapcsolat elsőbbség adatainak célértékét az adatkapcsolati réteghez továbbított LIDU Q számába kell leképezni a 4-26. táblázatban meghatározottak szerint. Ezt az értéket kell használni, amíg a kapcsolat felépítési eljárás be nem fejeződik.

4.7.3.15.4.2 Az ISO 8208 hívás elfogadva csomagban egy kapcsolati elsőbbség adatainak kiválasztott értékét az adatkapcsolati réteghez továbbított LIDU Q számba kell leképezni a 4-26. táblázatban meghatározottak szerint. Ezt az értéket kell használni az SNC hátralévő részében.

4.7.3.15.4.3 Ha egy érvénytelen elsőbbségi érték fordul elő a hívás-kérési vagy hívás elfogadva kötegben, akkor az SSNDPX-nek vissza kell utasítania a hívást. A törlés-kérő csomagban lévő hibakereső kódot "kapcsolat visszautasítása – a kívánt szolgáltatási minőség nem áll rendelkezésre – (állandó feltétel)"-re kell állítani.

4.7.3.15.4.4 Ha a hívá-skérő csomagban egy kapcsolat adatainak elsőbbsége nem kerül jelzésre, akkor egy előre beállított alapértéket (SNC elsőbbség = 0) kell alkalmazni.

4.7.3.15.5 *AZ ÁTERESZTŐ TELJESÍTMÉNY SZERINTI OSZTÁLY-EGYEZTETÉS*

4.7.3.15.5.1 Az áteresztőt eljesítmény szerinti osztály-egyeztetést egymástól függetlenül minden adatátviteli irányban alkalmazni kell.

4.7.3.15.5.2 *Áteresztő teljesítmény*

Az áteresztő teljesítmény al-paraméterét a következő értékek valamelyikeként kell meghatározni (nem meghatározott, 75, 150, 300, 600, 1200, 2400, 4800, 9600, 19200, 48000, 64000 bit/s).

4.7.3.15.6 *ADAT-TOVÁBBÍTÁSI KÉSÉS*

4.7.3.15.6.1 Az egyeztetett adat-továbbítási késést mindkét irányban alkalmazni kell.

4.7.3.15.6.2 *Légijármű által kezdeményezett kapcsolat létrehozása*

4.7.3.15.6.2.1 Az SSNDPA-nak az adat-továbbítási késés kiválasztási és kijelzési (TDSAI) értékét a hívás-kérő csomagban közvetlenül le kell képeznie a kapcsolat-kérő SNDPU ugyanazon beállítási értékébe.

4.7.3.15.6.2.2 Ha az SSNDPG egy hívás elfogadva köteget vesz az IWF-től válaszul egy beérkező TDSAI szolgáltatással, akkor a kapcsolat-megerősítő SNPDU-ban lévő ugyanazon szolgáltatást kell továbbítani az SSNDPA-hoz.

4.7.3.15.6.3 *Földi kezdeményezésű kapcsolat létrehozása*

Ha az SSNDPG az IWF-től TDSAI szolgáltatással rendelkező hívás-kérési csomagot vesz, akkor az SSNDPG-nek a kapcsolat-kérő SNPDU-ban az adat-SNPDU műholdas al-hálózati tranzitkéséseként egy 131 oktettből álló középértéket kell továbbítania az SSNDPA felé.

4.7.3.15.7 *GYORS KIVÁLASZTÁS*

A gyors kiválasztási szolgáltatást a következők szerint kell kezelni:

a) Egy gyors kiválasztás szolgáltatás kérés nélküli hívás-kérés csomagot úgy kell leképezni, hogy az SNPDU válaszban nem szerepel a korlátozás (használat nincs megengedve) a gyors kiválasztásra vonatkozóan;
b) Egy gyors kiválasztás szolgáltatás kérést jelző hívás-kérés csomagot - ha nincs válasz-korlátozás, akkor - úgy kell leképezni a kapcsolat-kérésbe, hogy az SNPDU válaszban nem szerepel a korlátozás (használat nincs megengedve) a gyors kiválasztásra vonatkozóan;

c) Egy gyors kiválasztás kérést jelző gyors kiválasztás kérést - ha van válasz-korlátozás, akkor - úgy kell leképezni a kapcsolat-kérésbe, hogy az SNDPU-válaszban szerepeljen a korlátozás (használat nincs megengedve) a gyors kiválasztásra vonatkozóan.

4.7.3.15.8 *GYORSÍTOTT ADAT-EGYEZTETÉS*

A hívás-kérő vagy hívás elfogadva csomagban lévő gyorsított adat-egyeztetési szolgáltatás kérést nem szabad leképezni a megfelelő kapcsolat-kérő vagy kapcsolat-megerősítő SNPDU-ba, hacsak a beállítási érték nincs "a gyorsított adatok nincsenek használva"-ra állítva.

4.7.3.15.9 *OK ÉS HIBAKERESŐ KÓDOK*

4.7.3.15.9.1 A törlés ok, a visszaállítás ok és a hibakereső kód mezőket a csomagokból módosítás nélkül kell a megfelelő SNPDU-hoz eljuttatni.

4.7.3.15.9.2 Ha az SSNDPX kezdeményezte a törlési vagy visszaállítási eljárást, akkor a törlés okot, a visszaállítás okot és a hibakereső kód mezőket a 4-16. és 4-17. táblázatban foglaltak szerint kell beállítani.

4.7.3.15.10 *ADATOK*

4.7.3.15.10.1 Ha egy M-bites csomag sorozat adatcsomagjaiban lévő felhasználói adat mező kisebb mint az adat-SNPDU maximális felhasználói adat mező-hossz előre beállított alapértéke, akkor ezeket a mezőket egy M-bites SNDPU sorozatként kell megformálni.

4.7.3.15.10.2 Ha egy M-bites csomag sorozat adatcsomagjaiban lévő felhasználói adat mező nagyobb mint az adat-SNPDU maximális felhasználói adat mező-hossz előre beállított alapértéke, akkor ezeket a mezőket egy M-bites SNDPU sorozat kialakítására szegmensekre kell osztani.

4.7.3.16 AZ SNPDU-NAK CSOMAGBA VALÓ LEKÉPEZÉSI SZABÁLYAI

4.7.3.16.1 Ezt a részt az SNPDU mezőknek az ISO 8208 kcsomagok megfelelő mezőibe való leképezésének szabályai szerint kell meghatározni.

4.7.3.16.2 *DTE CÍM*

4.7.3.16.2.1 A kapcsolat-kérő SNPDU-ban lévő hívott DTE cím és hívó DTE cím mezőket közvetlenül kell leképezni a hívott DTE címbe és hívó DTE cím- ezőkbe a beérkező hívás-csomagban.

4.7.3.16.2.2 Mind a hívó, mind a hívott DTE cím mezőket újra létre kell hozni akkor, amikor egy hívás kapcsolva csomag kerül továbbításra, ha azok jelen voltak a megfelelő hívás-kérő csomagban.

4.7.3.16.3 *NSAP CÍM*

4.7.3.16.3.1 A kapcsolat-kérő SNPDU-ban lévő hívott NSAP címet és a hívó NSAP cím mezőt közvetlenül kell leképezni a hívott cím kiterjesztésbe és hívó cím kiterjesztési paraméter-mezőkbe a beérkező híváskcsomagban.

4.7.3.16.3.2 A kapcsolat megerősítő vagy kapcsolat megszakítva SNPDU-ban lévő hívott NSAP cím mezőt a hívás kapcsolva vagy törlés jelző csomagban lévő hívott cím kiterjesztési mezőbe kell leképezni.

4.7.3.16.4 *ELSŐBBSÉG*

A kapcsolat-kérő és kapcsolat-megerősítő SNPDU-khoz társított Q számot az adatok cél- és kiválasztott elsőbbségi értékeibe kell leképezni az ISO 8208 beérkező hívásban és hívás kapcsolva csomagban lévő elsőbbség beállítás kapcsolati mezőben.

4.7.3.16.5 *ÁTERESZTŐ TELJESÍTMÉNY SZERINTI OSZTÁLY-EGYEZTETÉS*

4.7.3.16.5.1 Az áteresztő teljesítmény szerinti osztály-egyeztetést egymástól függetlenül minden adatátviteli irányban alkalmazni kell.

4.7.3.16.5.2 *Áteresztő teljesítmény*

Az áteresztő teljesítmény al-paraméterét a következő értékek valamelyikeként kell meghatározni (nem meghatározott, 75, 150, 300, 600, 1200, 2400, 4800, 9600, 19200, 48000, 64000 bit/s).

4.7.3.16.6 *ADAT-TOVÁBBÍTÁSI KÉSÉS*

4.7.3.16.6.1 Az egyeztetett adat-továbbítási késést mindkét irányban alkalmazni kell.

4.7.3.16.6.2 *A légijármű által kezdeményezett kapcsolat létrehozása.*

4.7.3.16.6.2.1 Ha az SSNDPG egy kapcsolat-kérő SNPDU-t vesz egy TDSAI szolgáltatással rendelkező SSNDPA-tól, akkor az SSNDPG-nek az IWF részére az adat-SNPDU műholdas al-hálózati átlagos tranzitkéséseként egy 131 oktettből álló értéket kell továbbítania a beérkező hívás-csomagban.

4.7.3.16.6.2.2 Az SSNDPA-nak a kapcsolat-megerősítő SNPDU-ban lévő TDSAI beállítási értéket közvetlenül kell leképeznie a hívás kapcsolva csomagban lévő ugyanazon beállítási értékbe.

4.7.3.16.6.3 *Földi kezdeményezésű kapcsolat létrehozása*

4.7.3.16.6.3.1 Az SSNDPA-nak a kapcsolat-kérő SNPDU-ban lévő TDSAI beállítási értéket közvetlenül kell leképeznie a beérkező híváscsomagban lévő ugyanazon beállítási értékbe.

4.7.3.16.6.3.2 Ha az SSNDPG egy hívás-megerősítő SNPDU-t vesz az SSNDPA-tól válaszul egy TDSAI szolgáltatás kapcsolat-kérő SNDPU-ra, akkor a hívás kapcsolva kötegben lévő ugyanazon szolgáltatást kell továbbítani az IWF felé.

4.7.3.16.7. *GYORS KIVÁLASZTÁS*

A gyors kiválasztás szolgáltatást a következők szerint kell kezelni:

a) Egy olyan kapcsolat-kérést, amely nem korlátozza a gyors kiválasztás szolgáltatási kérést (használat nincs megengedve), azt a válasz-SNPDU beérkező hívás-csomagba a gyors kiválasztás nélkül kell leképezni.

b) Egy olyan kapcsolat-kérést, amely nem korlátozza a gyors kiválasztás szolgáltatási kérést (használat nincs megengedve), azt a válasz-SNPDU beérkező hívásкötegbe a gyors kiválasztás szolgáltatásnak a ("válasz nincs korlátozva") paraméterével kell leképezni.

c) Egy olyan kapcsolat-kérést, amely korlátozza a gyors kiválasztás szolgáltatási (használat nincs megengedve) kérést, azt a válasz-SNPDU beérkező hívásкötegbe a gyors kiválasztás szolgáltatási "válasz korlátozva" paraméterével kell leképezni.

4.7.3.16.8 *GYORSÍTOTT ADAT-EGYEZTETÉS*

Ha a gyorsított adat-egyeztetés szolgáltatás nincs jelen a kapcsolat-kérő vagy kapcsolat- megerősítő SNPDU-ban, akkor ezt a szolgáltatási értéket a paraméterének "gyorsított adatok használata"-ra állításával hozzá kell adni a megfelelő beérkező híváshoz vagy kapcsolt hívás csomaghoz; ellenkező esetben ezt a szolgáltatást a megfelelő csomaghoz kell leképezni.

4.7.3.16.9 *OK ÉS HIBAKERESŐ KÓDOK*

A törlés ok, visszaállítás ok és hibakereső kódmezőket az SNPDU-kból módosítás nélkül kell a megfelelő csomagokhoz továbbítani.

4.7.3.16.10 *ADATOK*

4.7.3.16.10.1 Ha egy M-bites SNPDU sorozat adat-SNPDU-iban lévő felhasználói adat mező kisebb mint az adat-csomag maximális felhasználói adat mező hossz előre beállított alapértéke, akkor ezeket a mezőket egy M-bites csomag sorozat kialakítására össze kell kapcsolni.

4.7.3.16.10.2 Ha egy M-bites SNPDU sorozat adat-SNPDU-iban lévő felhasználói adat mező nagyobb mint az adatcsomag maximális felhasználói adat mező-hossz előre beállított alapértéke, akkor ezeket a mezőket egy M-bites csomagsorozat kialakítására szegmensekre kell felosztani.

4.7.3.17 KAPACITÁS

Az SSNDPA-nak egyidejűleg legalább nyolc egymástól független logikai csatornát kell alátámasztania.

4.7.4 ISO 8208 DCE protokol üzemelések

4.7.4.1 ÁLTALÁNOS ELŐÍRÁSOK

4.7.4.1.1 Az ISO 8208 DCE és az ISO 8208 DTE közötti protokolnak meg kell felelni az ISO 8208 második kiadásának.

4.7.4.1.2 *CSOMAG RÉTEG ENTITÁS*

Megjegyzés. – Az ISO 8208 DCE-n belül egynél több DCE/DTE interfész is lehet, pl. egy GES egynél több földi ATN útvonal-kijelöléshez is kapcsolódhat. Egy ilyen entitás létezik a DCE-ben minden DCE/DTE interfész esetében. Annak eldöntése, hogy melyik entitást kell használni egy rendeltetési hely elérésére, az az itt meghatározott protokolhoz egy külsőleg végrehajtott funkció. A 4.7.4 pontban meghatározott protokol a DCE-ben lévő minden csomag réteg entitásre vonatkozik.

4.7.4.2 MEGFELELÉSI KÖVETELMÉNYEK

4.7.4.2.1 *TÁMOGATOTT SZOLGÁLTATÁSOK ÉS KÉPESSÉGEK*

A következő szolgáltatásokat és képességeket kell alátámasztani:

a) virtuális hívás szolgáltatás;

b) 128 oktettnyi felhasználói adatmező az adatcsomagokban; és

c) gyorsított adat-átvitel, azaz egy 32 oktettig terjedő felhasználói adatmezővel alkalmazott megszakító csomagok használata.

4.7.4.2.2 *TÁMOGATOTT SZOLGÁLTATÁSOK*
A következő szolgáltatásokat kell alátámasztani:

a) a hívó cím kiterjesztése és hívott cím kiterjesztése;

b) elsőbbség.

Megjegyzés. – Egy kapcsolat elérésére és fenntartására szolgáló legkisebb cél és elfogadható értékeket, valamint egy kapcsolat adatainak a legkisebb elfogadható értékeit nem kell alátámasztani.

4.7.4.2.3 *AJÁNLOTT SZOLGÁLTATÁSOK*

Ajánlás. – *A következő szolgáltatásokat kell alátámasztani:*

a) átmeneti teljesítmény osztály-egyeztetés;

b) adat-továbbítási késés kiválasztása és jelzése;

c) gyors kiválasztás;

d) gyors kiválasztás elfogadása.

4.7.4.3 ÜZEMELÉSEK

4.7.4.3.1 *KÜLSŐ KÖLCSÖNHATÁSOK*

Megjegyzés. – Bizonyos DCE eljárások kezdeményezését az ISO 8208 DCE-n kívüli elemek irányítják. Hasonlóan, bizonyos ISO 8208 DCE események előfordulását ennek megfelelően kell jelenteni. Ezek a külső kölcsönhatások a következőket foglalják magukba:

a) az adatkapcsolati réteg kérése, kimenő csomagok továbbítása;

b) vétel, az adatkapcsolati rétegtől beérkező csomagok;

c) kérések fogadása az IWF-től bizonyos ISO 8208 protokol eljárások kezdeményezésére, beleértve:

1) egy virtuális hívás kezdeményezése;

2) egy virtuális hívás fogadása;

3) egy virtuális hívás befejezés;,

4) adat- és megszakítási információ átvitele; és

5) egy logikai csatorna újra-inicializálása.

d) bizonyos ISO 8208 protokol események előfordulásának jelentése az IWF-nek, ideértve:

1) egy virtuális hívás beállítására szóló beérkező kérés vétele;

2) egy virtuális hívás beállítása elfogadásának vétele;

3) egy virtuális hívás befejezése;

4) adat- és megszakítási információk vétele; és

5) egy logikai csatorna újra inicializálása.

4.7.4.3.1.1 Az ISO 8208 DCE-nek az összes hiba nélküli ISO 8208 csomagot el kell fogadnia az ISO 8208
DTE-től.

4.7.4.3.2 *LOGIKAI CSATORNÁK*

Megjegyzés. – Minden egyes virtuális hívás és állandó virtuális áramkör kap egy logikai csatorna-azonosítót, ami egy, az 1-től 4095-ig terjedő tartományban lévő szám. Minden virtuális hívás esetén egy logikai csatorna-azonosító kerül kijelölésre a hívás beállítási fázisa során egy korábban elfogadott logikai csatorna-azonosító tartományból. Minden állandó virtuális áramkör esetén egy logikai csatorna-azonosító kerül kijelölésre a DTE-vel egyetértésben. A DCE-knek a logikai csatornák egy bizonyos ideig tartó használatáról a DTE-vel történik megegyezés.

4.7.4.3.3 *ÁLLAPOT ÁTMENETEK*

4.7.4.3.3.1 Az ISO 8208 műszaki előírásai és meghatározásai formátum meghatározásokra, hibakereső és ok kódokra, szolgáltatási regisztrációs protokolokra (ha használnak) és a forgalom-vezérlésre vonatkoznak az ISO 8208 interfészen.

1. Megjegyzés. – Az ISO 8208 DCE egy állapot-gépként került meghatározásra. Egy ISO 8208 csomag a DTE-től kiválthat állapot átmenetet, csakúgy, mint az IWF-től érkező csomag. A következő állapot átmenet (ha van ilyen), ami akkor történik, amikor a DCE a DTE-től egy csomagot fogad, a 4-29. ÷ 4-34. táblázatokban van meghatározva. Ezek a táblázatok a 4-31. ábrán lévő felépítés szerint vannak elrendezve.

2. Megjegyzés. – Egy csomag fogadásakor a cselekmény szabályosnak vagy hibásnak minősül az "A =" bevitel alatt. A kialakult állapotot az "S =" bevitel jelzi.

4.7.4.3.3.2 Ha egy állapot átmenet meg van határozva, akkor az elvégzendő tevékenységnek a 4-29. ÷ 4-34. táblázatokban meghatározottak szerintinek kell lenni.

4.7.4.3.4 *A CSOMAGOK ELRENDEZÉSE*

Amikor a DTE-től egy csomag érkezik, a 4-29 ÷ 4-34. táblázatokban a zárójelekben szereplő kifejezések azt határozzák meg, hogy a csomagot továbbítani kell-e, vagy sem az IWF-nek. Ha a zárójelben nincs megjegyzés felsorolva, vagy úgy van felsorolva, mint nem továbbított, akkor a csomagot érvényteleníteni kell. Az ISO 8208 DCE-nek az IWF felől egy csomagot vagy továbbítania kell, vagy nem a DTE-nek oly módon, amely kompatibilis az ISO 8208-cal.

4.7.4.3.5 *HIBAKERESŐ ÉS OK KÓDOK.*

Bizonyos feltételek esetén a 4-29. – 4-34. táblázatok egy hibakereső kódot közölnek, amit a jelzett állapotba való belépéskor az előállított csomagnak tartalmaznia kell. A "D =" kifejezésnek a hibakereső kódot kell jelölnie. Amikor "A = DIAG", akkor az elvégzendő cselekménynek egy ISO 8208 hibakereső csomag létrehozásának és a DTE-hez való továbbításának kell lenni; a jelzett hibakereső kódnak kell meghatározni a csomag hibakereső mezőjének tartalmát. Bármely csomagtípus ok mezőjében az ok mező 8-as bitjét 0-ra kell állítani annak jelzésére, hogy a feltételt az ISO 8208 interfész felismerte.

Megjegyzés. – A 4-29. – 4-34. táblázatokat úgy határozták meg, hogy az SSNDPX és ISO 8208 DCE funkciók egyidejűleg tudnak működni. Míg az aszinkron működés megfelelő megvalósítási stratégiát jelent, az SSNDPX és ISO 8208 üzemelések számára az nem követelmény.

4.7.4.3.6 *DCE IDŐZÍTŐ*

Megjegyzés. – Bizonyos körülmények között a DTE-nek egy, a DCE-től kibocsátott csomagra megadott időn belül kell válaszolni.

4.7.4.3.6.1 A 4-35. táblázat tartalmazza azokat a körülményeket és a tevékenységet, amelyeket a DCE-nek kezdeményeznie kell a megadott idő lejáratakor.

4.7.4.4 KAPACITÁS

Az AES DCE-nek legalább nyolc egyidejű, egymástól független logikai csatornát kell alátámasztania.

4.7.4.5 VIRTUÁLIS HÍVÁS /VC/ KIZÁRÁS

A legkisebb elsőbbségű logikai csatornát és a társított virtuális hívást törölni kell, ami a magasabb elsőbbségű szolgáltatás iránti kérés fogadásához szükséges.

Megjegyzés. – A logikai csatornáknak és virtuális hívásoknak 0 elsőbbségű szintjük van, hacsak az ISO 8208 elsőbbségi szolgáltatás aktiválásra nem került a hívás beállításakor.

4.7.5 Összerendező funkció

4.7.5.1 SSNDPX/IWF INTERFÉSZ

4.7.5.1.1 Az IWF és az SSNDPX között kicserélt ISO 8208 csomagoknak a 4-36. táblázatban meghatározottak szerintinek kell lenni.

4.7.5.1.2 *BEÉRKEZŐ HÍVÁS CSOMAG KEZELÉSE*

Az IWF-nek a gyorsított adat-egyeztetés szolgáltatással és "gyorsított adatok használata" paraméterrel beérkező hívás csomagot a megfelelő ISO 8208 DCE entitáshoz kell továbbítani.

Megjegyzés. – Ha a szolgáltatás paraméterében "nincs gyorsított adathasználat", akkor az IWF a beérkező hívás csomagot vagy ezzel a beállítási értékkel, vagy nélküle továbbítja.

4.7.5.1.3 *HÍVÁS KAPCSOLÁSOS CSOMAG KEZELÉS*

Ha a gyorsított adat-egyeztetés szolgáltatás paramétere "gyorsított adatok használata"-ra van állítva a hívás kapcsolásos csomagban, akkor az IWF-nek ezt a beállítási értéket és paraméterét a csomaggal továbbítania kell a megfelelő ISO 8208 DCE entitáshoz. Minden virtuális hívás esetén az IWF-nek az SSNDPX logikai csatornáját társítania kell a megfelelő ISO 8208 DCE logikai csatornához.

Megjegyzés. – Ha a gyorsított adat egyeztetés szolgáltatás paramétere "nincs gyorsított adathasználat"-ra van állítva, akkor az IWF vagy ezzel az értékkel, vagy enélkül továbbítja a hívás kapcsolási csomagot.

4.7.5.1.4 *TÖRLÉS JELZŐ CSOMAG KEZELÉS*

4.7.5.1.4.1 Az IWF-nek el kell különítenie az SSNDPX logikai csatornát a megfelelő ISO 8208 DCE logikai
csatornától és a csomagot az ISO 8208 DCE entitáshoz kell továbbítania.

4.7.5.1.5 *AZ ADAT, A MEGSZAKÍTÁS, A MEGSZAKÍTÁS-MEGERŐSÍTÉS ÉS A VISSZAÁLLÍTÁS CSOMAG KEZELÉSE.*

4.7.5.1.5.1 Az adat, a megszakítás, a megszakítás-megerősítés és a visszaállítás jelzési csomagokat a megfelelő ISO 8208 DCE entitáshoz kell továbbítani egy kapcsolat létrehozásának befejezése után létrehozott logikai csatorna-társításra alapozva.

4.7.5.2 ISO 8208 DCE/IWF INTERFÉSZ

4.7.5.2.1 Az IWF és az ISO 8208 DCE között kicserélt ISO 8208 csomagoknak a 4-37. táblázatban meghatározottaknak megfelelőnek kell lenni.

4.7.5.2.2 *A HÍVÁS-KÉRŐ CSOMAG KEZELÉS*

Ha a hívás-kérő csomag nem tartalmazza a gyorsított adat-egyeztetés szolgáltatást, akkor az IWF-nek ezt a beállítási értéket a "nincs gyorsított adathasználat"-ra állított paraméterével hozzá kell adnia a csomaghoz és továbbítania kell a megfelelő SSNDPX entitáshoz; más esetben az IWF-nek a hívás-kérő csomagot ezzel a beállítási értékkel és paraméterrel kell továbbítani. Ha az opcionális hívott DTE cím érvénytelen, akkor az IWF-nek egy törlés jelző csomagot kell visszaküldenie az ISO 8208 entitásnak.

4.7.5.2.3 *ELFOGADOTT HÍVÁS CSOMAG KEZELÉS*

Ha az elfogadott hívás csomag nem tartalmazza a gyorsított adategyeztetés szolgáltatást, akkor az IWF-nek ezt a szolgáltatást a paraméterével "nincs gyorsított adathasználat"-ra állítva hozzá kell adnia a csomaghoz és a megfelelő SSNDPX entitáshoz kell továbbítania; más esetben az IWF-nek az elfogadott hívás csomagot ezzel az értékkel és paraméterrel kell továbbítania. Minden virtuális hívás esetén az IWF-nek az ISO 8208 DCE logikai csatornát társítania kell a megfelelő SSNDPX logikai csatornával.

4.7.5.2.4 *A TÖRLÉS-KÉRÉS CSOMAG KEZELÉSE*

Az IWF-nek el kell különítenie az ISO 8208 DCE logikai csatornát a megfelelő SSNDPX logikai csatornától, és a csomagot az SSNDPX entitáshoz kell továbbítania.

4.7.5.2.5 *AZ ADAT, A MEGSZAKÍTÁS, A MEGSZAKÍTÁS-MEGERŐSÍTÉS ÉS A VISSZAÁLLÍTÁS CSOMAG KEZELÉSE*

Az adat, a megszakítás, a megszakítás-megerősítés és a visszaállítás kérő csomagokat a megfelelő SSNDPX entitáshoz kell továbbítani egy kapcsolat létrehozásának befejezése után létrehozott logikai csatorna-társításra alapozva.

4.7.5.3 (Fenntartott)
4.7.5.4
4.7.5.4 AZ ISO 8208 LOGIKAI CSATORNA ÉS SSNDPX LOGIKAI CSATORNA TÁRSÍTÁSA

Megjegyzés. – Az ISO 8208 DCE logikai csatornaa zonosítónak és egy SNC SSNDPX logikai csatorna azonosítójának nem kell azonosnak lennie.

4.7.5.5 ADAT-ÁTVITELI ELJÁRÁSOK

4.7.5.5.1 *FORGALOM-VEZÉRLÉS*

Forgalom-vezérlést kell alkalmazni az SSNDPX és az ISO 8208 DCE között a tárolt adatok túlcsordulásának megelőzése céljából.

4.7.5.6 OK ÉS HIBAKERESŐ KÓDOK

4.7.5.6.1 Az IWF-nek ki kell cserélnie a DCE-től érkezett ISO 8208 csomagokban lévő "helyi eljárási hiba" okot a "távoli eljárási hiba" okra, mielőtt azokat az SSNDPX részére továbbítaná. Az IWF-nek ki kell cserélnie az SSNDPX-től érkezett SNPDU-ban lévő "helyi összeköttetési hiba" okot a "hálózati torlódás" okra, mielőtt azt a DCE-nek továbbítaná. Az összes egyéb okot változtatás nélkül kell továbbítani.

4.7.5.6.2 A hibakereső kódokat változtatás nélkül kell továbbítani.

4.7.6 Kezelési interfész

4.7.6.1 AES KEZELÉSI INTERFÉSZ

4.7.6.1.1 Az AES kezelési interfésztől az SSNL-hez továbbított bejelentkezési helyzet változásainak a 4.9.2.1.1 pontban meghatározottak szerintinek kell lenni.

4.7.6.1.2 Amikor az AES vagy kijelentkezik vagy egyéb módon szünteti meg a GES-sel az összeköttetést, akkor az AES SSNL-nek ezzel a GES-sel az összes kapcsolatot törölnie kell.

4.7.6.1.3 *ÖSSZEKAPCSOLHATÓSÁGI (CN) ÉRTESÍTÉS ESEMÉNY*
4.7.6.1.3.1 A CN funkciót a CN entitás által kell végrehajtani.

4.7.6.1.3.1 *bis* Összekapcsolási és elhagyási esemény

Az AES-nek összekapcsolási és elhagyási esemény üzenetet kell szolgáltatni a légijármű útvonal-kijelölési funkciója részére annak jelzésére, hogy a levegő-föld adatkapcsolat rendelkezésre áll, vagy hogy nem áll rendelkezésre, külön-külön. Az összekapcsolási és elhagyási üzenetnek elegendő információt kell tartalmaznia az útvonal-kijelölő funkció részére ahhoz, hogy megállapítsa a bejelentkező GES-hez csatolt DTE(k) címét (címeit).

Megjegyzés. – Ez végrehajtható például a GES/műhold ID-nek az AES-től az útvonal-kijelölő funkcióhoz történő továbbításával, amely kereső táblázatot tartalmaz a DTE cím(ek)re vonatkozóan, azért, hogy a DTE címe(ke)t közvetlenül az AES-től az útvonal-kijelolő funkcióhoz továbbítsa.

4.7.6.1.3.2 (Fenntartott)

4.7.6.1.3.3 (Fenntartott)

4.7.6.2 GES VEZÉRLÉSI INTERFÉSZ

4.7.6.2.1 A GES vezérléstől az SSNL-hez továbbított bejelentkezési állapot változásainak a 4.10.3.2 pontban meghatározottaknak kell lenni.

4.7.6.2.2 Amikor az AES kijelentkezik a GES-től, akkor az SSNL-nek az AES-sel társított összes kapcsolatot törölnie kell, és fel kell szabadítania az ezen SNC(k)-hez társított összes forrást. Továbbá, a GES-nek biztosítania kell a csatolt ATN földi útvonal-kijelölők részére egy elhagyási esemény jelzést a 24-bites ICAO légijármű azonosító hivatkozásával.

4.8 ÁRAMKÖRI ÜZEMMÓDÚ SZOLGÁLTATÁSOK

4.8.1 Légiforgalmi mozgó-műholdas (R) szolgálat /AMS(R)S/ áramköri üzemmód általános követelményei

Megjegyzés. – Az AMS(R)S áramköri üzemmódú szolgáltatás egy hírközlés iszolgáltatás a légijárművek és a földi berendezések között, amely az összeköttetési eszközök egyikeként a műholdas összeköttetéseket használja. Az AMS(R)A áramkör üzemmódú szolgáltatás lehetőséget biztosít egy megosztás nélküli, központokon keresztül felépített áramkör létrehozására és fenntartására a légijárművek és földi felhasználók között, igény esetén. Az áramköri üzemmódú szolgáltatás elsődleges célja a biztonságos rádiótávbeszélő összeköttetés biztosítása. A központokon keresztül felépített áramkört a hívás időtartamára hozzák létre, hacsak automatikusan ki nem jelölték tartalék-forrásoknak egy magasabb elsőbbségű hívás-kísérlet számára történő újbóli kiosztására. Az AMS(R)S központokon keresztül felépített áramkörök összekapcsolhatók egy vagy több földi telepítésű hírközlési berendezéssel az AMS(R)S al-hálózattal tandemben. Ezek a berendezések magukban foglalhatnak biztonsági kapcsolási hálózatokat vagy cél-orientált áramköröket.

4.8.1.1 *AMS(R)S áramköri üzemmódú szolgálatok.* Az áramkör üzemmódú AMS(R)S hírközlési szolgálatokat kell biztosítani a 3-as és 4-es szintű AES(k) számára. Ezeknek vészhelyzeti, sürgősségi, repülésbiztonsági és egyéb, meteorológiára, valamint repülési tevékenységekre vonatkozó közleményekből kell állni.

Megjegyzés. – Nem AMS(R)S áramköri kapcsolású, nem biztonsági kommunikációs célú beszéd-üzemű és adatszolgáltatást be nem avatkozási alapon támogathat az AMS(R)S, feltéve, hogy a 4.8.3.2 pont előírásai teljesülnek.

4.8.1.2 *Fontossági sorrend.* Az ATS összeköttetési célú AMS(R)S szolgáltatásoknak elsőbbséget kell élvezniük a nem-AMS(R)S összeköttetésekkel szemben.

4.8.1.3 *Nem-AMS(R)S összeköttetések.* A nem-AMS(R)S összeköttetés nem zavarhatja az AMS(R)S összeköttetést.

4.8.2 Az áramköri üzemmódú rendszer szerkezete

4.8.2.1 Az AES áramköri üzemmódú szolgáltatásoknak képesnek kell lenni a légi kezdeményezésű hívásokban használandó egyedi GES meghatározására és nem korlátozhatók a bejelentkezési GES-ekre. Fordítva, egy földről kezdeményezett hívást, amely bármely GES földi hálózattól érkezik és rendelkezik az AES aktuális-bejelentkezési információjával, inkább ezen GES által kell létrehozni, mintsem azon GES-sel, amelyikhez az AES bejelentkezett.

4.8.2.2 *Áramköir üzemmódú adatkapcsolati réteg jelző interfész.* Az AES és a GES áramköri üzemmódú szolgáltatási eljárásoknak az AMS(R)S adatkapcsolati réteget kell használniuk a jelző információ cseréjére. Ezt az információt áramköri üzemmódú- adatkapcsolati interfész adat egységekben (CM-LIDU) kell szállítani. Az adatkapcsolati réteg felhasználójaként, az AMS(R)S áramköri üzemmódú eljárásoknak a 4.5 és 4.6 pontokban meghatározott adatkapcsolati interfész szolgáltatásait kell használni. Minden CM-LIDU-nak az adatkapcsolati réteg által megkövetelt specifikus adatkapcsolati réteg vezérlés információs (LICI) paraméterekből kell állnia. A CM-LIDU-kat és vonatkozó (LICI) paramétereiket a 4-38. táblázat határozza meg.

4.8.2.3 ÁRAMKÖR ÜZEMMÓDÚ TELEFON-TECHNIKAI ÖSSZEDOLGOZÓ INTERFÉSZ

Megjegyzés. – Az áramkör üzemmódú telefon-technikai összedolgozó interfész útmutató anyagát az I. Rész A-Függeléke tartalmazza.

4.8.2.3.1 Az AES és GES áramköri üzemmódú szolgáltatás eljárásainak az ITU CCITT Q.601-Q.608 ajánlásoknak megfelelő, szabványosított összedolgozó telefon-technikai eseményekből álló összedolgozó interfészen keresztül együtt kell dolgoznia külső telefon-technikai hálózatokkal. Az áramköri üzemmódú eljárások által használt össze- dolgozó telefon-technikai események készletének, valamint az események és a megfelelő CM-LIDU-k közötti leképező paraméterekkel szemben támasztott követelményeknek a 4-39. ÷ 4-42. táblázatokban meghatározottak szerintinek kell lenni.

Megjegyzés. – Az ITU CCIT Q.601-Q.608 ajánlások részleteit a CCITT Kék Könyv, VI. Kötet - VI. 6. Füzete tartalmazza.

4.8.2.4 EGYÉB AES ÁRAMKÖRI ÜZEMMÓDÚ RENDSZER INTERFÉSZEK

4.8.2.4.1 *AES kezelési interfész.* Az AES áramköri üzemmódú szolgáltatások és AES kezelés között kicserélt specifikus információknak a 4.9 pontban meghatározottak szerintinek kell lenniük.

4.8.2.4.2 *AES beszéd-üzemű kodek külső interfész.* Az AES külső beszéd-üzemű interfésznek kétirányú beszéd-üzemű információt kell szállítania a légijármű-specifikus audio-rendszereknek megfelelő formában.

4.8.2.5 EGYÉB GES ÁRAMKÖR ÜZEMMÓDÚ RENDSZER INTERFÉSZEK

4.8.2.5.1 *GES kezelési interfész.* A GES áramköri üzemmódú szolgáltatások és GES kezelés között kicserélt specifikus információknak a 4.10 pontban meghatározottak szerintinek kell lenni.

4.8.2.5.2 *Beszéd-üzemű kodek külső interfész.* A GES külső beszéd-üzemű interfésznek kétirányú hangcsatornás információt kell szállítania a földi hálózat audio-csatornáinak megfelelő formában.

4.8.3 Az AMS(R)S szolgáltatás követelményei

4.8.3.1 *Összekapcsolhatóság.* Az AMS(R)S szolgáltatásnak alá kell támasztania a központokon keresztül kapcsolt áramkörök kérésre történő létrehozását egy GES szolgáltatási területén belül lévő bármely légijármű és a GES-t kiszolgáló földi hálózatok között. Az AMS(R)S szolgáltatásnak lehetővé kell tenni egy áramköri kapcsolási tranazakció létrehozását egy légijármű és egy földi hálózat között egy olyan GES-en keresztül, amelyik nem azonos azzal a GES-sel, amelyikhez a légijármű bejelentkezett.

4.8.3.2 *Elsőbbség és előjog.* Az AMS(R)S hívásoknak elsőbbséggel kell rendelkezniük minden nem-AMS(R)S hívással szemben, és szükség esetén képesnek kell lenniük a nem-AMS(R)S hívásokkal szemben előjog érvényesítésére az áramköir üzemmód szolgáltatás azonnali elérésének biztosítása céljából. Az AMS(R)S hívásokat a 4-43. táblázatban meghatározott elsőbbségi szintekkel összhangban kell létrehozni és fenntartani. Egy folyamatban lévő AMS(R)S hívásnál magasabb elsőbbséggel rendelkező AMS(R)S hívásnak képesnek kell lennie az alacsonyabb szolgáltatási elsőbbségel rendelkező hívással szemben előjog érvényesítésére az áramkör üzemmódú szolgáltatás azonnali elérésének biztosítása céljából. Egy GES és egy földi hálózat közötti interfészen áthaladó összes AMS(R)S hívási kísérletet a társított elsőbbségi kategóriának megfelelően kell meghatározni.

4.8.3.3 *Szolgáltatási minőség.* A GES-nek olyan megfelelő mennyiségű C-csatorna forrással kell rendelkeznie, hogy egy légi, vagy földi kezdeményezésű hívás GES-nél történő vételénél, a GES-en belüli blokkolás valószínűsége ne legyen nagyobb 0,01-nél. A rendelkezésre álló GES C-csatorna forrásoknak az összes hátrasorolható forrást (mint pl. azok, amelyeket a nem-biztonsági felhasználók használnak) magukba kell foglalni.

4.8.4 Az AMS(R)S teljesítmény követelmények

4.8.4.1 HÍVÁS-FELDOLGOZÁSI KÉSÉSEK

1. Megjegyzés. – Az AMS(R)S al-hálózat hozzáférési késés teljesítmény-követelményeinek útmutató anyaga, valamint az, hogy azok milyen hatást gyakorolnak a földfelszíni ATS hálózatok tervezésére, az I. Rész A-Függelékében található.
2. Megjegyzés. – Az A5-1a) a "hozzáférés késés" CM-LIDU, az, amely az A2-45. és A2-46. ábrákon bemutatott két különböző hozzáférési kérés SU egyikével kapcsolódik. Az első az alapszinti szabvány, a második az, amely valamivel kisebb kapcsolat létrehozási késést szolgáltat.

4.8.4.1.1 *LÉGI KEZDEMÉNYEZÉS*

4.8.4.1.1.1 *A GES jelzés továbbítási késése.* Egy GES esetében a földfelszíni hálózat összedolgozó interfésze felé irányuló hívás-kezdeményezési esemény előállítására (lásd 4-42. táblázat, FITE 18) a GES adatkapcsolati rétegben lévő összes AES hívási információ első beérkezése utáni maximális időbeli késés 1,0 másodperces kell, hogy legyen (95 százalék).

Megjegyzés. – Az AES hívás információkat az R-csatornán keresztül vett "hozzáférés kérés" CM-LIDU és a C-csatornán keresztül vett CM-LIDU önmagában tartalmazza. Az A2-45. és A2-46. ábra két hozzáférés kérés SU-t mutat be.

4.8.4.1.1.2 *GES C-csatorna kijelölés késés.* A GES maximális időbeli késésének egy "C-csatorna kijelölés" CM-LIDU-nak a P-csatorna adatkapcsolati réteg általi kiszolgálására való felsorakoztatásához, egy "hozzáférési kérés" CM-LIDU-nak a GES-be történő érkezését követően, 1,5 másodpercnek kell lenni (95 százalék).

4.8.4.1.1.3 *Az AES C-csatorna kijelölés válaszának késése.* Az AES maximális időbeli késésének egy C-csatorna vivőfrekvencia kisugárzásának megkezdéséhez, miután egy "C-csatorna kijelölés" CM-LIDU érkezett az AES adatkapcsolati rétegbe, 1,0 másodpercnek kell lenni (95 százalék).

4.8.4.1.2 *FÖLDI KEZDEMÉNYEZÉSEK*

4.8.4.1.2.1 *A GES C-csatorna kijelölés késése.* Egy GES maximális időbeli késésének a P-csatorna által szolgáltatott "C-csatorna kijelölés" CM-LIDU felsorakoztatására egy hívás kezdeményező esemény (lásd 4-41. táblázat, FITE 18) a földi telepítésű összedolgozó interfészhez való megérkezését követően, 1,5 másodpercnek kell lenni (95 százalék).

4.8.4.1.2.2 *Az AES C-csatorna kijelölés késése.* Az AES maximális időbeli késésének egy C-csatorna vivőfrekvencia kisugárzásának a "hívás bejelentés" CM-LIDU és a "C-csatorna kijelölés" CM-LIDU-nak az AES adatkapcsolati rétegben történő megérkezését követő megkezdéséhez, 1,0 másodpercnek kell lenni (95 százalék).

Megjegyzés. – A földi kezdeményezésű hívások AES eljárásai egy AES-től megkívánják, hogy megvárja mindkét CM-LIDU sikeres vételét, mielőtt a C-csatorna adása elkezdődhet. Ezek az eljárások a rendes sorrendtől eltérő potenciális vétel kezelését szolgáló hibajavító logikát foglalják magukba.

4.8.4.2 ÁTVITELI KÉSÉS

4.8.4.2.1 Az AMS(R)S al-hálózatban egy 21,0 kbit/s sebességgel működő C-csatorna teljes megengedhető átviteli késése nem lehet több, mint 0,485 másodperc.

4.8.4.2.2 Az AES-nek és GES-nek tulajdonítható maximális átviteli késésnek egyenként 0,080 másodpercnek kell lenni.

1. Megjegyzés. - Az RF terjedési késésnek (legrosszabb terjedési útvonal geometria) a 0,285 másodperc és a vokóder keret-kisugárzási késésének a 0,040 másodperc rögzített átviteli késési összetevőt jelölték ki. A 0,040 másodperces vokóder keret-kibocsátási késés a legrosszabb szinkronizáció esetére vonatkozik, amikor az első 0,020 másodperces vokóder beszéd-üzemű keret egy további C-csatorna összerendező blokk által késést szenved.

2. Megjegyzés. – Az AMS(R)S al-hálózat teljes átviteli késését úgy határozták meg, mint azt az időt, amely attól a pillanattól kezdődik, amikor a beszéd eljut az AES-hez, vagy a GES-hez és abban a pillanatban ér véget, amikor a beszéd a GES vagy AES megfelelő párjainak összekapcsolódó hálózatába belép. Ez a késés tartalmazza a vokóder feldolgozási idejét, a fizikai réteg késését, az RF terjedési késését és bármilyen más, az AMS(R)S al-hálózaton belül lévő késést.

4.8.4.3 ÚTVONAL-TÉVESZTÉS

A belső feldolgozás vagy jelzési hibák által okozott GES-en belüli útvonal-tévesztések valószínűsége nem haladhatja meg az 1 per 10^6-t.

Megjegyzés. – Útvonal-tévesztés akkor fordulhat elő, ha a GES tévesen értelmezi (1) a hálózati azonosítót, vagy a "rövidített hozzáférési cím – telefon" CM-LIDU-ban lévő (légi kezdeményezés esetén) a földi címzés számjegyeit vagy (2) az AES azonosítót vagy a földi telepítésű hálózatnál (földi kezdeményezés esetén) az összedolgozó interfésztől kapott FITE 18-ban lévő terminál azonosítót.

4.8.5 Áramkör üzemmódú beszéd-üzemű kódoló/dekódoló

4.8.5.1 *Áramkör üzemmódú beszéd-üzem.* Áramkör üzemmódú beszéd-üzemnél mindegyik C-csatornához a megfelelő beszéd-üzemű kódoló/dekódolós algoritmust kell használni az AES-nél és a GES-nél, ahogyan az alábbiakban jelezve van.

4.8.5.1.1 *21,0 kbit/s C-csatorna.* A 9,6 kbit/s-os kódoló/dekódoló algoritmust (lásd a 4. Fejezet 7. Függeléke) kell használni a 21 kbit/s C-csatornával (lásd 4.4.5 pont).

Megjegyzés. – A beszéd-üzemű kódoló algoritmus BT (korábban British Telecom) szabadalmi jogok és szerzői jogok által védett. A BT hozzájárult ahhoz, hogy ilyen szabadalmi jogok és szerzői jogok alatt szabadalmi díj mentes, nem kizárólagos licenceket nyújt az összes AES és GES előállítónak kizárólag a polgári repülési mobil műholdas összeköttetések megvalósítására (amelybe beletartoznak az AMSS és AMS(R)S összeköttetések, ahogyan az a 4. Fejezetben leíásra került). Ezek a gyártók a szabadalmi díj mentes licence megegyezést kötnek a BT Laboratories-el, mielőtt az algoritmust beépítik a polgári repülési mobil műholdas összeköttetésre szolgáló berendezésekbe.

4.8.5.1.2 *A 8,4 kbit/s C-csatorna.* A 4,8 kbit/s-es kódoló/dekódoló algoritmust kell használni a 8,4 kbit/s csatornával (lásd 4.4.5 pont).

Megjegyzés. – Az információkat a műszaki előírások 4,8 kbit/s-os kódoló/dekódoló algoritmus műszaki jellemzőiről a "Low Level Description" ("Alacsony szint ismertetése") dokumentum 1.5 számú, 1996. május 3-iki keltezésű, a Digital Voice Systems Inc (DVSI), Egyesült Államok által kialakított változata tartalmazza.

A dokumentumban ismertetett 4,8 kbit/s kódoló/dekódoló technológia DVSI szabadalmi jogok és szerzői jogok által védett. A gyártóknak licence egyezményt kell kötniük a DVSI-vel az algoritmus részletes leírásának megszerzését megelőzően, az AMSS szolgáltatást működtető berendezésbe való beépítése előtt. Az ICAO-nak címzett, 1998. november 10-ikén kelt levelében a DVSI megerősítette elkötelezettségét a technológia felhasználás engedélyezésére a légiközlekedési berendezések gyártói és eladói számára elfogadható feltételek mellett, amelyeket diszkrimináció mentes alapon tárgyaltak meg.

4.8.6. AMS(R)S áramkör üzemmódú eljárások

Az AMS(R)S áramkör üzemmódú eljárások a következő négy funkcionális területet ölelik fel:

a) Az AES áramkör üzemmódú szolgáltatások esetében:

i) AES kimenő logikai eljárás (légi kezdeményezésnél); és

ii) AES bejövő logikai eljárás (földi kezdeményezésnél).

b) A GES áramkör üzemmódú szolgáltatások esetében:

i) GES kimenő logikai eljárás (földi kezdeményezésnél); és

ii) GES bejövő logikai eljárás (légi kezdeményezésnél).

4.8.6.1 AMS(R)S ÁRAMKÖRI ÜZEMMÓDÚ ELJÁRÁSOK

1. Megjegyzés. – Elfogadott az, hogy egy AMS(R)S áramkör üzemmódú szolgáltatási eljárás az itt leírt eljárásokban külön meghatározott pontos kód értékek nélkül kódolni vagy értelmezni fogja bármely továbbított vagy vett CM-LIDU vonatkozó paramétereit. A paraméter-kódolásra vonatkozó specifikus követelmények a 4. Fejezet 5. Függelékében meghatározott összedolgozó telefon-technikai események leképezési követelményeiben találhatók.

2. Megjegyzés. – A "C-csatorna források" kifejezés magában foglal minden szükséges C-csatorna hardvert és a C-csatorna fenntartását biztosító elegendő adó-teljesítményt.

4.8.6.1.1 *AES ÁRAMKÖR ÜZEMMÓDÚ LOGIKA*

Megjegyzés. – Az AES kimenő, illetve bejövő eljárások által az összedolgozó telefon-technikai események és CM-LIDU-k közötti leképezések követelményeit a 4. Fejezet 5. Függelékében az A5-1-től

A5-11-ig, illetve A5-12 - A-18-ig ábrák tartalmazzák. Az áramkör üzemmódú konfiguráció paramétereket (pl. a 4.8.6.1.1.1 pontban használtakat) a 4. Fejezet 6. Függeléke határozza meg.

4.8.6.1.1.1 *AES kimenő áramkör üzemmódú eljárás.* Egy “AMS(R)S hívás-kezdeményezés”-i eseménynek (FITE 18) az összedolgozó interfésznél történő vétele arra kell, hogy indikálja az AES áramkör üzemmódú
szolgáltatásokat, hogy egy egyedi alkalmazási referencia-számot jelöljenek ki a hívás részére. Ezt követően az AES áramkör üzemmódú szolgáltatásoknak a következőket kell végezniük:

a) ha nem áll rendelkezésre elegendő AES C-csatorna forrás, és a blokkolás azoknak a hívásoknak tulajdonítható, amelyek az adott hívási kisérlettel azonos vagy nagyobb C-csatorna elsőbbségű számmal üzemelnek, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívás sikertelen – hálózati torlódás”-i eseményt (BITE 12) kell visszaküldeniük az összedolgozó interfészhez és minden hívási tevékenységet be kell fejezniük; vagy

b) ha elegendő C-csatorna forrás áll rendelkezésre, vagy ha a blokkolást okozó hívások legalább egyike az adott hívási kisérletnél kisebb C-csatorna elsőbbségű számmal üzemel, akkor az AES áramkör üzemmódú szolgáltatásoknak az alábbiakat kell végrehajtani, és azt követően egy GES áramköri üzemmódú szolgálattól érkező C-csatorna kijelölésre kell várniuk.

1) ha a hívás elsőbbségű vészhelyzeti/sürgősségi, akkor az AES áramkör üzemmódú szolgáltatásoknak az nA21 “hozzáférés kérés – telefon” CM-LIDU-kat kell az adatkapcsolati réteghez továbbítaniuk; vagy

2) ha a hívás elsőbbsége repülésbiztonsági, akkor az AES áramkör üzemmódú szolgáltatásoknak az nA22 “hozzáférési kérés – telefon” CM-LIDU-kat kell az adatkapcsolati réteghez továbbítaniuk; vagy

3) ha a hívás elsőbbsége üzemeltetési rendszerességű/meteorológiai, akkor az AES áramkör üzemmódú szolgáltatásoknak az nA23 “hozzáférési kérés – telefon” CM-LIDU-kat kell az adatkapcsolati réteghez továbbítaniuk.

4.8.6.1.1.1.1 Az AES áramkör üzemmódú szolgáltatásoknak az alábbiakat kell végrehajtani, miközben a GES áramköri üzemmódú szolgálatoktól érkező válaszokra várakoznak:

a) Ha a GES áramkör üzemmódú szolgáltatásoktól a legutolsó "hozzáférési kérés – telefon” CM-LIDU elküldése után tA50 másodperccel nem érkezik válasz, akkor az AES-nek egy R-csatorna frekvencia kiválasztására kell utasítást adnia, és azt követően az eredeti mennyiségű CM-LIDU-t továbbítani kell, feltéve, hogy a CM-LIDU sorozat újra-továbbításainak teljes száma nem haladja meg a négyet. Ha a CM-LIDU sorozat negyedik újra-továbbítása után tA50 másodperccel nem érkezett válasz, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívás sikertelen – vonal üzemen kívül” eseményt (BITE 17) kell az összedolgozó interfészhez visszaküldeniük és minden hívási tevékenységet meg kell szüntetniük; vagy

b) ha egy “törlés továbbítás” esemény (FITE 22) kerül vételre az összedolgozó interfésznél, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívás folyamat csatorna-felszabadítás” CM-LIDU-t kell továbbítaniuk az R-csatornán az adatkapcsolati réteghez és minden hívási tevékenységet meg kell szüntetniük; vagy

c) ha a hívási kisérlet egy magasabb elsőbbségű hívás által hátrasorolódik, akkor az AES áramkör üzemmódú szolgáltatásoknak egy a “hívott bont” eseményt (BITE 25) az összedolgozó interfészhez, és egy “hívási folyamat – csatorna-felszabadítás” CM-LIDU-t az adatkapcsolati réteghez kell továbbítaniuk az R-csatornán, és minden hívási tevékenységet be kell fejezniük; vagy

d) ha az alábbiak közül bármelyik válasz érkezik, az AES áramkör üzemmódú szolgáltatásoknak a következőket kell végezniük:

1) Ha akár egy “hívás folyamat – hívás kisérlet eredménye” CM-LIDU vagy egy “hívási folyamat – csatorna-felszabadítás” CM-LIDU érkezik, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívott bont” eseményt (BITE 25), vagy egy megfelelő “sikertelen hívás” eseményt (BITE 14, 15, 16, 17 vagy 20) kell továbbítaniuk az összedolgozó interfészhez, amint azt a vett CM-LIDU-ban lévő ok helyzet, ok osztály és ok érték-paraméterek meghatározzák. Ezt követően az AES áramkör üzemmódú szolgáltatásoknak minden hívási tevékenységet meg kell szüntetniük; vagy

2) ha egy “C-csatorna kijelölés”-i CM-LIDU kerül vételre, akkor az AES áramkör üzemmódú szolgáltatásoknak C-csatorna források kiosztására kell felkérniük az AES vezérlést és aktiválniuk kell egy C- csatorna Q szám értékkel bíró kijelölt frekvencián egy C-csatorna egységet a 4-43. táblázat szerint.

Megjegyzés. – Ez azt jelenti, hogy a C-csatorna Q számát az adatkapcsolati rétegben lévő áramkör üzemmódú kezdeti hívás-jelzésben használt Q számból származtatják.

Azt követően az AES áramköri üzemmódú szolgálatoknak egy “hívás-tájékoztatás-szolgálatok cím” CM-LIDU-t kell meghatározatlan időn keresztül az adatkapcsolati réteghez továbbítaniuk minden tA29 másodpercben és összeköttetést kell teremteniük a C-csatorna audio interfésze, valamint a hívó interfésze között.

Megjegyzés. – A “hívás-tájékoztatás – szolgálati cím” CM-LIDU által szállított információ redundáns a “hozzáférési kérés” CM-LIDU által szállított információval, amikor a felhasznált hozzáférés kérési eljárás nem az “általános hozzáférés kérés” eljárás. Ebben az esetben ezt az információt a nem AMS(R)S felhasználóknak nyújtott AMSS szolgáltatást biztosító GES-ek által alkalmazott áramköri folytonossági teszt-eljárásokkal való kompatibilitás fenntartására használják; és ez az információ nem kerül benyújtásra a GES-hez digitális analízis elvégzése céljából.

4.8.6.1.1.1.2 Ha a C-csatorna egység aktiválását követő tA28 másodpercen belül nem érkezik válasz a GES áramkör üzemmódú szolgáltatástól, akkor az AES áramkör üzemmódú szolgáltatásoknak hat “hívási folyamat – csatorna megszakítás” CM-LIDU-t kell a C-csatorna alsávon keresztül küldeniük az adatkapcsolati réteghez, egy “sikertelen hívás – vonal üzemen kívül” eseményt (BITE 17) kell az összedolgozó interfészhez küldeniük küldeniük és minden hívási tevékenységet be kell szüntetniük, ellenkező esetekben az AES áramkör üzemmódú szolgáltatásoknak a következőket kell végezniük:

a) ha egy vagy több “hívás folyamat-ellenőrzés” CM-LIDU-k kerülnek vételre, akkor az AES áramkör üzemmódú szolgáltatásoknak azokat figyelmen kívül kell hagyniuk; vagy

b) ha egy vagy több “hívási folyamat-csatorna-megszakítás" CM-LIDU kerül vételre, vagy ha egy “bontás továbbítás” esemény (FITE 22) érkezik az összedolgozó interfészhez, akkor az AES áramkör üzemmódú szolgáltatásoknak hat “hívás folyamat-csatorna-megszakítás” CM-LIDU-kat kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez küldeniük, és egy megfelelő telefon-technikai eseményt (BITE 14, 15, 16, 17, 20, vagy 25) kell visszaküldeniük az összedolgozó interfészhez és meg kell szüntetniük minden hívási tevékenységet; vagy

c) ha egy “hívás folyamat – kapcsolás” CM-LIDU kerül vételre, vagy ha a CM-LIDU úgy érkezik, hogy megelőzi akár egy “hívási folyamat-ellenőrzés” CM-LIDU, vagy egy “hívási folyamat – hívási kisérlet eredménye” CM-LIDU, amelyeket korábban a C-csatorna egység aktivizálást követő tA28 másodpercen belül vettek, akkor az AES áramkör üzemmódú szolgáltatásoknak a következőket kell végezniük:

1) biztosítani kell, hogy a “hívás-információ - szolgálat cím” CM-LIDU ismétlődő továbbítása megszakadjon; és

2) egy “válasz” eseményt (BITE 22) kell továbbítani az összedolgozó interfészhez és az adatkapcsolati réteghez egy pozitív “telefon-technikai nyugtázás” CM-LIDU-t kell továbbítani a C-csatorna alsávon keresztül. Ha további “hívás folyamat – kapcsolás” CM-LIDU-k kerülnek vételre a kezdeti “hívás folyamat – kapcsolás” CM-LIDU-t követően, akkor az AES áramkör üzemmódú szolgáltatásoknak mindegyikre válaszolniuk kell egy pozitív “telefon-technikai nyugtázás” CM-LIDU-nak a GES áramkör üzemmódú szolgáltatás adatkapcsolati rétegéhez való továbbításával; vagy

Megjegyzés. – Ezen a ponton a végponttól végpontig hívás jön létre.

d) ha egy “hívás folyamat – hívás kisérlet eredménye” CM-LIDU (egy “címzés komplett” esemény jelzésére bekódolva) kerül vételre, vagy ha az úgy érkezik, hogy megelőzi egy “hívási folyamat – ellenőrzés” CM-LIDU, amit korábban a C-csatorna egység aktivizálását követő tA28 másodpercen belül vettek, akkor az AES áramkör üzemmódú szolgáltatásoknak a következőket kell végezniük:

1) biztosítani kell, hogy a “hívás-információ – szolgálat cím” CM-LIDU ismétlődő továbbítása megszakadjon, és

2) egy “címzés komplett” eseményt (BITE 5) kell továbbítani az összedolgozó interfészhez és az adatkapcsolati réteghez egy pozitív “telefon-technikai nyugtázás” CM-LIDU-t kell továbbítania a C-csatorna alsávon keresztül. Ha további “hívás folyamat - hívási kísérlet eredménye” CM-LIDU-k kerülnek vételre a kezdeti “hívás folyamat – hívás kísérlet eredménye” CM-LIDU-t követően, akkor az AES áramkör üzemmódú szolgáltatásoknak mindegyikre válaszolniuk kell egy pozitív “telefon-technikai nyugtázás”-i CM-LIDU-nak a GES áramkör üzemmódú szolgáltatások adatkapcsolati rétegéhez való továbbításával;

e) vagy ha a C-csatorna forrásokat hátrasorolják egy magasabb elsőbbségű hívás miatt, akkor az AED áramkör üzemmódú szolgáltatásoknak hat “hívás folyamat – csatorna-megszakítás” CM-LIDU-t kell a C- csatorna alsávon keresztül az adatkapcsolati réteghez továbbítaniuk, egy “hívott bont” eseményt (BITE 25) kell visszaküldeniük az összedolgozó interfészhez, és meg kell szűntetniük minden hívási tevékenységet; vagy

f) ha C-csatorna alsávi adatkapcsolati réteg a hívás beszüntetésére ad utasítást, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívott bont” eseményt (BITE 25) kell az összedolgozó interfészhez továbbítaniuk és be kell szüntetniük minden hívási tevékenységet.

4.8.6.1.1.2 *AES bejövő áramkör üzemmódú eljárás.* Ezt az eljárást az alábbi egymással kölcsönös összefüggésben lévő eljárásoknak kell meghatározniuk:

a) AES bejövő áramköri üzemmódú hívás-kezdeményezés – 4.8.6.1.1.2.1;

b) AES bejövő C-csatorna folyamatosság ellenőrzés – 4.8.6.1.1.2.2.;

c) AES bejövő légijármű felőli befejezés – 4.8.6.1.1.2.3;

d) AES bejövő C-csatorna fenntartás – 4.8.6.1.1.2.4.

4.8.6.1.1.2.1 *AES bejövő áramkör üzemmódú hívás-kezdeményezés.* Akár egy “hívás-bejelentés vagy egy egyedi alkalmazási referencia-számmal bíró “C-csatorna kijelölés” CM-LIDU vételekor, az AES áramkör üzemmódú szolgáltatásoknak a következőket kell elvégezniük:

a) ha egy “C-csatorna kijelölés” került vételre, akkor az AES áramkör üzemmódú szolgáltatlásoknak egy negatív “telefon-technikai nyugtázás” CM-LIDU-t (a “hívás-bejelentés” CM-LIDU hiányának jelzésére kódolva) kell az R-csatornán keresztül az adatkapcsolati réteghez továbbítaniuk és a következőket kell végrehajtaniuk:

1) ha sem egy vonatkozó “hívás-bejelentés” CM-LIDU, sem egy “hívás folyamat – csatornafelszabadítás” CM-LIDU nem érkezik a legutolsó negatív “telefon-technikaii nyugtázás” CM-LIDU továbbítását követő tA27 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak a negatív “telefon-technikai nyugtázás” CM-LIDU-t az R-csatornán keresztül az adatkapcsolati réteghez kell továbbítaniuk és megérkezésükre további tA27 másodpercet kell várniuk; feltéve, hogy a “telefon-technikai nyugtázás” CM-LIDU ismétléseinek teljes száma nem haladja meg a négyet. Ha az előbbiekben említett CM-LIDU-k egyike sem érkezik meg a “telefon-technikai nyugtázás” CM-LIDU negyedik megismétlését követő tA27 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívás folyamat – hívás kisérlet eredménye” CM-LIDU-t kell az R-csatornán keresztül az adatkapcsolati réteghez továbbítaniuk és meg kell szüntetniük minden hívási tevékenységet; vagy

2) ha egy “hívási folyamat – csatorna-felszabadítás” CM-LIDU érkezik a “telefon-technikai nyutázás” CM-LIDU legutolsó továbbítását követő tA27 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak meg kell minden hívási tevékenységet szüntetniük; vagy

3) ha a hívást egy magasabb elsőbbségű hívás miatt hátrább kell sorolni, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívás folyamat – hívás kisérlet eredménye” CM-LIDU-t kell az R csatornán keresztül az adatkapcsolati réteg felé továbbítaniuk és minden hívási tevékenységet meg kell szüntetniük; vagy

4) ha a vonatkozó “hívás-bejelnlés” CM-LIDU a “telefon-technikai nyugtázás” CM-LIDU legutolsó továbbítását követő tA27 másodpercen belül kerül vételre, akkor az AES áramkör üzemmódú szolgáltatásoknak a következőket kell végezniük:

i) ha a hívott terminál egy olyan hívás által foglalt, amelynek előbbségi száma egyenlő vagy magasabb a folyamatban lévő hívás elsőbbségi számával, vagy ha a C-csatorna források nem állnak rendelkezésre, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívás folyamat – hívás kísérlet eredménye” CM-LIDU-t kell az R-csatornán az adatkapcsolati réteghez továbbítaniuk és minden hívási tevékenységet meg kell szüntetniük; vagy

ii) ha mind a hívott terminál, mind a C-csatorna források rendelkezésre állnak, akkor az AES áramkör üzemmódú szolgáltatásoknak az AES kezelést fel kell kérniük C-csatorna források kijelölésére és egy C- csatorna Q számértékkel bíró C-csatorna egység kijelölt frekvencián történő aktivizálására a 4-43. táblázat szerint.

Megjegyzés. – Ez azt jelenti, hogy a C-csatorna Q számát az adatkapcsolati rétegben lévő áramkör üzemmódú kezdeti hívás-jelzésben használt Q számból származtatják.

Ezt követően az AES áramkör üzemmódú szolgáltatásoknak egy “hívási folyamat – ellenőrzés” CM-LIDU-t kell az adatkapcsolati réteghez továbbítaniuk, és a 4.8.6.1.1.2.2 pont alatti AES beérkező C-csatorna folyamatossági ellenőrzési eljárást kell végrehajtaniuk; vagy

b) ha egy “hívás-bejelentés” CM-LIDU került vételre, akkor az AES áramkör üzemmódú szolgáltatásoknak a következőket kell végezniük:

1) ha egy “hívás folyamat – csatorna-bontás” CM-LIDU érkezik a “hívás-bejelentés” CM-LIDU vételét követő tA25 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak minden hívási tevékenységet meg kell szüntetniük; vagy

2) ha sem egy “C csatorna kijelölés” CM-LIDU, sem egy “hívás folyamat – csatorna-megszakítás” CM-LIDU nem érkezik a “hívás-bejelentés” CM-LIDU vételét követő tA25 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak egy negatív “telefon-technikai nyugtázás” CM-LIDU-t (a “C-csatorna kijelölés” CM-LIDU hiányának jelölésére bekódolva) kell az R-csatornán keresztül az adatkapcsolati réteghez továbbítaniuk és további tA27 másodpercet kell várniuk azok megérkezésére.

Ha tA27 másodperc elteltével a CM-LIDU-k egyike sem érkezik meg, akkor az AES áramkör üzemmódú szolgáltatásoknak a negatív “telefon-technikai nyugtázás” CM-LIDU-t ismét továbbítaniuk kell az adatkapcsolati réteghez és újabb tA27 másodpercet kell várniuk; feltéve, hogy a negatív “telefon-technikai nyugtázás” CM-LIDU-k ismétléseinek teljes száma nem haladja meg a négyet. Ha a negatív “telefon-technikai nyugtázás” CM-LIDU negyedik ismétlését követő tA27 másodpercen belül sem érkezik meg egyik CM-LIDU sem, akkor az AES áramkör üzemmódú szolgálatoknak egy “hívás folyamat – hívás kisérlet eredménye” CM-LIDU-t kell az R-csatornán keresztül az adatkapcsolati réteghez továbbítani, és minden hívási tevékenységet meg kell szüntetniük; vagy

3) ha a hívást egy magasabb elsőbbségű hívás miatt hátrább kell sorolni, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívás folyamat – hívás kisérlet eredménye” CM-LIDU-t kell az R cstornán keresztül az adatkapcsolati réteghez továbbítaniuk és minden hívási tevékenységet meg kell szüntetniük; vagy

4) ha egy “C-csatorna kijelölés” CM-LIDU kerül vételre akár a “hívás-bejelentés” CM-LIDU vételét követő tA25 másodpercen belül, akár a legutolsó negatív “telefon-technikai nyugtázás” CM-LIDU kisugárzásának vételét követő tA27 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak a következőket kell végrehajtaniuk:

i) ha a hívott terminál egy olyan hívás által foglalt, amelynek elsőbbsági száma egyenlő vagy magasabb a folyamatban lévő hívás elsőbbségi számával, vagy ha C-csatornaforrások nem állnak rendelkezésre, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívás folyamat – hívás kísérlet eredménye” CM-LIDU-t kell az R-csatornán az adatkapcsolati réteghez továbbítaniuk, és minden hívási tevékenységet meg kell szüntetniük; vagy

ii) ha mind a hívott terminál, mind a C-csatorna források rendelkezésre állnak, akkor az AES áramkör üzemmódú szolgáltatásoknak az AES kezelést fel kell kérniük a 4-43. táblázat szerinti C-csatorna Q számértékkel bíró források kijelölésére és a kijelölt frekvencián egy C-csatorna egység aktivizálására. Azt követően az AES áramkör üzemmódú szolgáltatásoknak egy “hívási folyamat – ellenőrés” CM-LIDU-t kell az adatkapcsolati réteghez továbbítaniuk és végre kell hajtaniuk a 4.8.6.1.1.2.2 pont alatti AES bejövő C- csatorna folyamatossági ellenőrzési eljárást.

4.8.6.1.1.2.2 *AES bejövő C-csatorna folyamatossági ellenőrzés.* Amint az a 4.8 pontban más helyen megkövetelt, az AES áramkör üzemmódú szolgáltatásoknak C-csatorna folyamatossági ellenőrzést kell teljesíteniük a következők végrehajtásával:

a) ha sem egy “hívás folyamat – ellenőrzés” CM-LIDU, sem egy “hívás folyamat – csatorna-megszakítás” CM-LIDU nem érkezik a legutolsó “hívás folyamat – ellenőrzés” CM-LIDU továbbításától számított tA26 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak egy másik “hívás folyamat – ellenőrzés” CM-LIDU-t kell az adatkapcsolati réteghez továbbítaniuk, amíg az alábbiak közül valamelyik meg nem történik:

1) ha sem egy “hívás folyamat – ellenőrzés” CM-LIDU, sem egy “hívás folyamat – megszakítás” CM-LIDU nem érkezik a C-csatorna egység aktivizálását követő tA41 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak le kell állítania a “hívás folyamat – ellenőrzés” CM-LIDU-k továbbítását, majd egy “hívás folyamat – hívás kísérlet eredménye” CM-LIDU-t kell az R-csatornán továbbítaniuk az adatkapcsolati réteghez és minden hívási tevékenységet meg kell szüntetniük; vagy

2) ha egy “hívás folyamat – csatorna-megszakítás” CM-LIDU kerül vételre a C-csatorna egység aktivizálását követő tA41 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak minden hívási tevékenységet meg kell szüntetniük; vagy

3) ha a C-csatornát egy magasabb elsőbbségű hívás miatt hátrább kell sorolni, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívási folyamat – hívás kisérlet eredménye” CM-LIDU-t kell az R-csatornán keresztül az adatkapcsolati réteghez továbbítaniuk és minden hívási tevékenységet meg kell szüntetniük; vagy

4) ha egy “hívás kísérlet – ellenőrzés” CM-LIDU kerül vételre a C-csatorna egység aktivizálást követő tA41 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásoknak létre kell hozni a C-csatorna egység és a légijármű hálózat továbbító áramköre közötti áramköri útvonalat. Ezt követően az AES áramkör üzemmódú szolgáltatásoknak egy pozitív “telefon-technikai nyugtázás” CM-LIDU-t kell a C-csatorna alsávon át az adatkapcsolati réteghez továbbítaniuk, egy “AMS(R)S hívás-kezdeményezés” eseményt (FITE 18) kell az összedolgozó interfészhez továbbítaniuk és várakozniuk kell a hívott terminálhoz menő hívás befejezésére, amint az az AES bejövő légijárművi befejezési eljárás 4.8.6.1.1.2.3 pontjában meg van határozva.

4.8.6.1.1.2.3 *AES bejövő légijárművi befejezése.* Amint az a 4.8 pontban máshol előírásra kerül, az AES áramkör üzemmódú szolgáltatásoknak a következőket kell végrehajtani egy hívott terminálhoz a légijárművi hálózaton keresztül eljuttatott hívás befejezésére:

a) ha egy vagy több “hívási folyamat – ellenőrzés” CM-LIDU került vételre, akkor az AES áramkör üzemmódú szolgáltatásnak egy pozitív “telefon-technikai nyugtázás” CM-LIDU-t kell továbbítani a C-csatorna alsávon át az adatkapcsolati réteghez; vagy

b) ha nem érkezik “válasz” esemény (BITE 22) az összedolgozó interfésztől az “AMS(R)S hívás-kezdeményezés” esemény (FITE 18) továbbítását követő tA42 másodpercen belül, vagy ha a C-csatornát egy magasabb elsőbbségű hívás miatt hátrább kell sorolni, akkor az AES áramkör üzemmódú szolgáltatásoknak egy “hívó bont” eseményt (FITE 22) kell az összedolgozó interfészhez küldenie, hat “hívási folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon át az adatkapcsolati réteghez továbbítania és minden hívási tevékenységet meg kell szüntetnie; vagy

c) ha egy "hívás-folyamat - csatorna-megszakítás" CM-LIDU kerül vételre, tA42 másodpercen belül, az "AMS(R)S hívás-kezdeményezés" esemény (FITE 18) továbbítása után, vagy ha a C-csatornát egy magasabb elsőbbségű hívás miatt hátrább kell sorolni, akkor a AES áramkör üzemmódú szolgáltatásnak egy 'hívó bont" eseményt (FITE 22) kell küldenie az össszedolgozó interfészhez hat "hívás-folyamat - csatorna-megszakítás" CM-LIDU-t kell a C-csatorna alsávon át az adatkapcsolati réteghez továbbítania, és minden hívási tevékenységet meg kell szűntetnie; vagy

d) ha egy “válasz” esemény (BITE 22) érkezik az összedolgozó interfésztől az “AMS(R)S hívás-kezdeményezés” esemény (FITE 18) továbbítását követő tA42 másodpercen belül, akkor az AES áramkör üzemmódú szolgáltatásnak egy “hívás folyamat – kapcsolás” CM-LIDU-t kell az adatkapcsolati réteghez továbítania, és végre kell hajtania a 4.8.6.1.1.2.4 pontban meghatározott AES bejövő C-csatorna fenntartási eljárást.

4.8.6.1.1.2.4 *AES bejövő C-csatorna fenntartás.* Amint azl a 4.8 pontban más helyen előírásra kerül, az AES áramkör üzemmódú szolgáltatásnak lehetővé kell tennie a végpont-végpont közötti kapcsolat folytatását, miközben az alábbiakat elvégzi a C-csatorna fenntartása céljából:

a) ha az utolsó “hívás folyamat – kapcsolás” CM-LIDU továbbítását tkövetően tA26 másodpercen belül sem egy pozitív “telefon-technikai nyugtázás” CM-LIDU, sem egy “hívott bont” esemény (BITE 25) nem érkezik az összedolgozó interfésztől, akkor az AES áramkör üzemmódú szolgáltatásnak a “hívás folyamat – kapcsolás” CM-LIDU-t ismét továbbítania kell a C-csatorna alsávon át az adatkapcsolati réteghez; vagy

b) ha az első “hívás folyamat – kapcsolás” CM-LIDU továbbítását követő tA30 másodpercen belül sem egy pozitív “telefon-technikai nyugtázás” CM-LIDU, sem egy “hívott bont” esemény (BITE 25) nem érkezik az összedolgozó interfésztől, akkor az AES áramkör üzemmódú szolgáltatásnak a “hívás folyamat – kapcsolás” CM-LIDU továbbítását le kell állítania, egy “hívó bont” eseményt (FITE 22) kell továbbítania az összedolgozó interfészhez, hat “hívási folyamat – csatorna-megszakítás” CM-LIDU-t kell továbbítania a C-csatorna alsávon át az adatkapcsolati réteghez és minden hívási műveletet meg kell szüntetnie; vagy

c) ha az első “hívás folyamat – kapcsolás” CM-LIDU továbbítását követő tA30 másodpcen belül egy “hívás folyamat – csatorna-megszakítás” CM-LIDU kerül vételre, akkor az AES áramkör üzemmódú szolgáltatásnak le kell állítania a “hívási folyamat – kapcsolás” továbbítását, egy “hívó bont” eseményt (FITE 22) kell az összedolgozó interfészhez küldenie, hat “hívási folyamat – csatorna-megszakítás” CM-LIDU-t kell a C- csatorna alsávon át továbbítania az adatkapcsolati réteghez, és minden hívási tevékenységet be kell fejeznie; vagy

d) ha a C-csatornát egy magasabb elsőbbségű hívás miatt hátrább kell sorolni, akkor az AES áramkör üzemmódú szolgáltatásnak egy “hívó bont” eseményt (FITE 22) kell küldenie az öddzrdolgozó interfészhez, hat “hívás folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon át továbbítania az adatkapcsolati réteghez ,és minden hívási tevékenységet meg kell szüntetnie; vagy

e) ha egy vagy több pozitív “telefon-technikai nyugtázás” CM-LIDU kerül vételre, akkor az AES áramkör üzemmódú szolgáltatásnak le kell állítania a “hívás folyamat – kapcsolás” CM-LIDU-k továbbítását és az alábbiakat kell végrehajtania, miközben lehetővé teszi a C-csatorna működését:

Megjegyzés. – Ez a helyzet abban a logikai eljárásban, ahol a végpont-végpont távközlési csatorna kész a használatra és a légi- és földi felhasználók megkezdhetik a "társalgás"-t.

1) ha egy “hívott bont” esemény (BITE 25) érkezik az összedolgozó interfésztől, akkor az AES áramkör üzemmódú szolgáltatásnak hat “hívás folyamat – csatornaf megszakítás” CM-LIDU-t kell a C-csatorna alsávon át az adatkapcsolati réteghez továbbítania, és minden hívási tevékenységet meg kell szüntetnie; vagy

2) ha egy “hívási folyamat – csatorna-megszakítás” CM-LIDU kerül vételre, akkor az AES áramkör üzemmódú szolgáltatásnak “hívó bont” eseményt (FITE 22) kell küldenie az összedolgozó interfészhez, hat “hívás folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon át az adatkapcsolati réteghez továbbítania, és minden hívási tevékenységet meg kell szüntetnie; vagy

3) ha a C-csatornát egy magasabb delsőbbségű hívás miatt hátrább kell sorolni, akkor az AES áramkör üzemmódú szolgáltatásnak “hívó bont” eseményt (FITE 22) kell küldenie az összedolgozó interfészhez, hat “hívási folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon át továbbítania az adatkapcsolati réteghez, és minden hívási tevékenységet meg kell szüntetnie; vagy

Megjegyzés. – A fenti logikai átmenetek figyelik a hívás-törlést vagy a normál hívás-bontás tevékenységen, vagy egy AES-kezdeményezésű C-csatorna hátrábbsoroláson keresztül.

f) ha a C-csatorna alsávi adatkapcsolati réteg a hívás befejezésére ad utasítást, akkor az AES áramkör üzemmódú szolgáltatásnak egy “hívó bont” eseményt (FITE 22) kell az összedolgozó interfészhez küldeni,e és minden hívási tevékenységet meg kell szüntetnie.

4.8.6.1.2 *GES ÁRAMKÖR ÜZEMMÓDÚ LOGIKA*

Megjegyzés. – A GES kimenő és bejövő eljárások által az összedolgozó telefon-technokai események és a CM-LIDU-k közötti leképezése követelményeit a 4. Fejezet 5. Függelékében az A5-19-től A5-27-ig és A5-8-tól A5-40-ig ábrák foglalják magukba.

4.8.6.1.2.1 *GES kimenő áramkör üzemmódú eljárás.* Ezt az eljárást az alábbi egymással kölcsönös összefüggésben lévő eljárásoknak kell meghatározni:

a) GES kimenő áramkör üzemmódú hívás-kezdeményezés – 4.8.6.1.2.1.1;

b) GES kimenő C- csatorna létrehozás – 4.8.6.1.2.1.2;

c) GES kimenő C-csatorna folyamatossági ellenőrzés – 4.8.6.1.2.1.3;

d) GES kimenő C-csatorna fenntartás – 4.8.6.1.2.1.4; és

e) GES kimenő C-csatorna felszabadítás őr – 4.8.6.1.2.1.5.

4.8.6.1.2.1.1 *GES kimenő áramkör üzemmódú hívás-kezdeményezés*. Egy “AMS(R)S hívás-kezdeményezés” esemény (FITE 18) vétele az összedolgozó interfészben arra kell, hogy késztesse a GES áramköri üzemmódú szolgáltatást, hogy az egy egyedi alkalmazási referencia-számot jelöljön ki a hívás számára. Ha az AES nincs bejelentkezve, akkor a GES áramkör üzemmódú szolgáltatásnak egy “sikertelen hívás – küldjön hibajelzést” eseményt (BITE 20) kell továbbítania az összedolgozó interfészhez és minden hívási tevékenységet meg kell szüntetnie; ellenkező esetben a GES áramkör üzemmódú szolgáltatásnak a GES vezérlést fel kell kérnie a hívás részére történő C-csatorna források 4-43. táblázat szerinti C-csatorna Q számmal való kijelölésre.

Megjegyzés. – Ez azt jelenti, hogy a C-csatorna Q számát az adat-kapcsolati rétegben lévő áramkör üzemmódú kezdeti hívás jelzésben használt Q számból származtatják.

Ezt követően a GES áramkör üzemmódú szolgáltatásnak a következőket kell végrehajtania:

a) ha egy “hívó bont” esemény (FITE 22) érkezik az összedolgozó interfészhez, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szűntetnie; vagy

b) ha a C-csatorna források nem állnak rendelkezésre, akkor a GES áramkör üzemmódú szolgáltatásnak egy “sikertelen hívás – hálózati torlódás” eseményt (BITE 12) kell továbbítania az összedolgozó interfészhez és minden hívási tevékenységet meg kell szűntetnie; vagy

c) ha a C-csatorna források rendelkezésre állnak, akkor a GES áramkör üzemmódú szolgáltatásnak egy olyan “hívás-bejelentés” CM-LIDU-t kell az adatkapcsolati réteghez továbbítania, amelyet azonnal követ egy “C- csatorna kijelölés” CM-LIDU. Ezt követően a GES áramkör üzemmódú szolgáltatásnak a GES vezérlést fel kell kérnie a korábban kijelölt C-csatorna egység kijelölt frekvencián történő aktivizálására, majd a C-csatorna 4.8.6.1.2.1.2 pont szerinti létrehozására.

4.8.6.1.2.1.2 *GES kimenő C-csatorna létrehozás.* Amint az a 4.8 pontban máshol előírásra kerül, a GES áramkör üzemmódú szolgáltatásnak a következőket kell végrehajtania egy földi kezdeményezésű C-csatorna használatának létrehozására:

a) ha, akár a “hívás-bejelentés” vagy a “C-csatorna kijelölés” CM-LIDU legutolsó továbbítását követő tG16 másodpercen belül egy negatív “telefon-technikai nyugtázás” CM-LIDU kerül vételre, akkor a GES áramkör üzemmódú szolgáltatásnak a vett CM-LIDU-ban jelzett hiányzó CM-LIDU-t ismét továbbítania kell az adatkapcsolati réteghez, és további tG16 másodpercig várakoznia kell; vagy

b) ha semmi sem érkezik az AES áramkör üzemmódú szolgáltatástól, akár a “hívás-bejelentés”, vagy a “C-csatorna kijelölés” CM-LIDU utolsó továbbítását követő tG16 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak mindkét CM-LIDU-t ismét továbbítania kell az adatkapcsolati réteghez -és további tG16 másodpercig várakoznia kell. Ha a további tG16 másodperces periódust követően sem érkezik semmi, akkor a GES áramkör üzemmódú szolgáltatásnak egy “sikertelen hívás – vonal üzemen kívül” eseményt (BITE 17) kell az összedolgozó interfésznek küldenie, és egy “hívás folyamat – csatorna-megszakítás” CM-LIDU-t kell a P-csatornán át az adatkapcsolati réteghez továbbítania. Ha a légijárműtől jövő vivőfrekvencia nincs jelen, akkor minden hívási tevékenységet meg kell szüntetnie; ellenkezp esetben, ha a C-csatorna légijárműtől jövő vivőfrekvencia nem szűnik meg az első “hívási folyamat – csatorna-megszakítás” CM-LIDU továbbítását követő tG23 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak ismét továbbítania kell a CM-LIDU-t. Ha a légijárműtől jövő vivőfrekvencia nem szűnik meg a második tG23 másodperces periódus lejártával, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetnie; vagy

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotát az ellenőrző funkcióhoz kell továbbítani.

c) ha egy “hívás folyamat – hívási kísérlet eredménye" CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak egy megfelelő “sikertelen hívás” eseményt (BITE 12, 16 vagy 17) kell az összedolgozó interfészhez küldenie. Továbbá, a GES áramkör üzemmódú szolgáltatásnak tG23 másodpercet várakoznia kell a C-csatorna légijárműtől jövő vivőfrekvenciájának megszűnésére. Ha a légijárműtől jövő vivőfrekvencia nincs jelen, akkor minden hívási tevékenységet meg kell szüntetnie, ellenkező esetben, ha a légijármű felől érkező vivőfrekvencia a periódus végére megszűnik, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetnie. Ha a légijárműtől jövő vivőfrekvencia nem szűnik meg ugyanazon perióduson belül, akkor a GES áramkör üzemmódú szolgáltatásnak a periódus minden hívás tevékenységét meg kell szüntetnie; vagy

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotot az ellenőrző funkcióhoz kell továbbítani.

d) ha egy “hívó bont” esemény (FITE 22) érkezik az összedolgozó interfészhez, akkor a GES áramkör üzemmódú szolgáltatásnak hat olyan “hívás folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon át az adatkapcsolati réteghez továbbítania, amelyet egy “hívás folyamat – csatorna-megszakítás” CM-LIDU követ a P-csatornán keresztül. Ezt követően a GES áramkör üzemmódú szolgáltatásnak végre kell hajtania a 4.8.6.1.2.1.5 pontban meghatározott C-csatorna felszabadítás őrző eljárást; vagy

e) ha egy “hívás folyamat – ellenőrzés” CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak egy “hívás folyamat – ellenőrzés” CM-LIDU-t kell az adatkapcsolati réteghez továbbítania, majd végre kell hajtania a 4.8.6.1.2.1.3 pontban meghatározott GES kimenő C-csatorna folyamatossági ellenőrző eljárást.

4.8.6.1.2.1.3 *GES kimenő C-csatorna folyamatosság ellenőrzés.* A földi kezdeményezésre használandó C-csatorna áramkör folyamatosságának ellenőrzésekor a GES áramkör üzemmódú szolgáltatásnak a következőket kell elvégeznie:

a) ha tG34 másodperc telt el az első “hívás folyamat – ellenőrzés” CM-LIDU-nak az AES áramkör üzemmódú szolgáltatáshoz való küldése óta, akkor a GES áramkör üzemmódú szolgáltatásnak egy “sikertelen hívás – vonal üzemen kívül” eseményt (BITE 17) kell az összedolgozó interfészhez küldenie és egy “hívás folyamat – csatornaf-megszakítás” CM-LIDU-t kell a P-csatornán keresztül az adatkapcsolati réteghez továbbítania. Ha a légijárműtől jövő vivőfrekvencia nincs jelen, akkor minden hívási tevékenységet meg kell szüntetnie; ellenkező setben, ha a C-csatorna légijárműtől jövő vivőfrekvencia nem szűnik meg a “hívás folyamat – csatornaf-megszakítás” CM-LIDU első továbbítását követő tG23 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak a CM-LIDU-t a P-csatornán keresztül ismét továbbítania kell és további tG23 másodpercig várakoznia kell. Ha a légijárműtől jövő vivőfrekvencia akármelyik periódus alatt megszűnik, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetnie. Ha a légijárműtől jövő vivőfrekvencia a második periódus végére nem szűnik meg, akkor a GES áramkör üzemmódú szolgáltatásnak a periódus végén minden hívási tevékenységet meg kell szüntetni; vagy

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotát az ellenőrző funkcióhoz kell továbbítani.

b) ha nem telt el tG34 másodperc az első “hívás folyamat – ellenőrzés” CM-LIDU-nak az AES áramkör üzemmódú szolgáltatáshoz való küldése óta, akkor a GES áramkör üzemmódú szolgáltatásnak a következőket kell végrehajtania, miközben ezzel egyidőben minden tG35 másodpercben egy “hívás folyamat – ellenőrzés” CM-LIDU-t továbbít az AES áramkör üzemmódú szolgáltatás adatkapcsolati rétegéhez.

1) ha egy “hívás folyamat – hívási kisérlet eredménye” CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak be kell fejeznie a “hívási folyamat – ellenőrzés” CM LIDU-k küldését az AES áramkör üzemmódú szolgáltatás részére. Ezt követően a GES áramkör üzemmódú szolgáltatásnak egy megfelelő “sikertelen hívás” eseményt (BITE 12, 16 vagy 17) kell az összedolgozó interfészhez továbbítania és tG23 másodpercet várakoznia kell a C-csatorna légijárműtől jövő vivőfrekvencia megszűnésére. Ha a légijárműtől jövő vivőfrekvencia nincs jelen, akkor minden hívási tevékenységet meg kell szüntetnie; ellenkező esetben, ha a légijármű felől érkező vivőfrekvencia megszűnik a periódus végére, akkor a GES áramkör üzemmódú szolgálatnak a periódus végén minden hívási tevékenységet be kell fejeznie. Ha a légijárműtől jövő vivőfrekvencia nem szűnik meg ennek az időpontnak a lejártáig, akkor a GES áramkör üzemmódú szolgálatnak a periódus végén minden hívási tevékenységet be kell fejeznie; vagy

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotát az ellenőrző funkcióhoz kell továbbítani.

2) ha egy “hívó bont” esemény (FITE 22) érkezik az összedolgozó interfészhez, akkor a GES áramkör üzemmódú szolgáltatásnak hat “hívási folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon át az adatkapcsolati réteghez továbbítania, meg kell állítania a “hívási folyamat – ellenőrzés” CM-LIDU-k továbbítását, majd végre kell hajtania a 4.8.6.1.2.1.5 pontban meghatározott GES kimenő C-csatorna felszabadítás őrző eljárását; vagy

3) ha egy “hívási folyamat – csatorna-megszakítás” CM-LIDU érkezik az AES áramkör üzemmódú szolgáltatástól, a GES áramkör üzemmódú szolgáltatásnak egy “hívott bont” eseményt (BITE 25) kell az összedolgozó interfészhez továbbítania és meg kell állítania a “hívás folyamat – ellenőrzés” CM-LIDU-k küldését. Ezt követően a GES áramkör üzemmódú szolgálatnak tG23 másodpercet várakoznia kell a C- csatorna légijárműtől jövő vivőfrekvenciájának megszűnésére. Ha a légijárműtől jövő vivőfrekvencia nincs jelen, minden hívási tevékenységet meg kell szüntetnie; ellenkező esetben, ha a légijárműtől jövő vivőfrekvencia a periódus alatt megszűnik, a GES áramkör üzemmódú szolgáltatásnak minden hívást meg kell szüntetnie. Ha a légijárműtől jövő vivőfrekvencia nem szűnik meg ezen perióduson belül, akkor a GES áramkör üzemmódú szolgáltatásnak a periódus végén minden hívási tevékenységet meg kell szüntetnie; vagy

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotát az ellenőrző funkcióhoz kell továbbítani.

4) ha egy pozitív “telefon-technikai nyugtázás” CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak meg kell állítania a “hívás folyamat – tellenőrzés” CM-LIDU-k továbbítását. Ezt követően a GES áramkör üzemmódú szolgáltatásoknak egy “címzés befejezés” eseményt (BITE 5) kell küldeni az összedolgozó interfészhez és végre kell hajtani a 4.8.6.1.2.1.4 pontban meghatározott GES kimenő C-csatorna fenntartási eljárást; vagy

5) ha egy “hívás folyamat – kapcsolás” CM-LIDU érkezik, a GES áramkör üzemmódú szolgáltatásnak meg kell állítani a “hívási folyamat – ellenőrzés” CM-LIDU-k továbbítását. Azt követően a GES áramkör üzemmódú szolgáltatásnak egy “címzés befejezés” eseményt (BITE 5) és egy “válasz” eseményt (BITE 22) kell küldeni az összedolgozó interfészhez, egy pozitív “telefon-technikai nyugtázás”-i CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez továbbítani és végre kell hajtani a 4.8.6.1.2.1.4 pontban meghatározott GES kimenő C-csatorna fenntartási eljárást.

4.8.6.1.2.1.4 *GES kimenő C-csatorna fenntartás.* Amint az más helyen a 4.8 pontban már megkövetelt, a GES áramkör üzemmódú szolgáltatásnak biztosítania kell a földi telepítésű hálózat továbbító áramköre és a C-csatorna egység közötti áramköri útvonalat, majd a következőket kell végrehajtania a C-csatorna fenntartása céljából:

a) a ha egy “hívási folyamat – kapcsolás” CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak egy pozitív “telefon-technikai nyugtázás” CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez továbbítania. Ha korábban nem érkezett egy azonos CM-LIDU a 4.8.6.1.2.1.2 pontban meghatározott GES kimenő C-csatorna létrehozási eljárás alatt, akkor a GES áramköri üzemmódú szolgáltatásnak az összedolgozó interfészhez szintén továbbítani kell egy “válasz” eseményt (BITE 22); vagy

b) ha egy “hívó bont” esemény érkezik az összedolgozó interfészhez, akkor a GES áramkör üzemmódú szolgáltatásnak hat “hívási folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez továbbítani. Ezt követően a GES áramkör üzemmódú szolgáltatásnak végre kell hajtani a 4.8.6.1.2.1.5 pontban meghatározott GES kimenő C-csatorna-bontás őrző eljárását; vagy

c) ha a C-csatorna légijárműtől érkező vivőfrekvenciája több mint tG19 másodpercig kimarad, akkor a GES áramkör üzemmódú szolgáltatásnak egy “hívott bont” eseményt (BITE 25) kell az összedolgozó interfészhez továbbítani. Ezt követően a GES áramkör üzemmódú szolgáltatásnak hat “hívásfolyamat – csatorna- megszakítás” CM-LIDU-t kell a C-csatorna alsávon az adatkapcsolati réteghez küldeni és végre kell hajtani a 4.8.6.1.2.1.5 pontban meghatározott C- csatorna-bontás őrző eljárását; vagy

d) ha a C-csatornát egy magasabb elsőbbségű hívás miatt hátrább kell sorolni, akkor a GES áramkör üzemmódú szolgáltatásnak egy “hívott bont” eseményt (BITE 25) kell az összedolgozó interfészhez továbbítani. Azt követően a GES áramkör üzemmódú szolgáltatásnak hat “hívás folyamat – csatorna-megszkítás” CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez küldeni, és végre kell hajtani a 4.8.6.1.2.1.5 pontban meghatározott GES kimenő C-csatorna bontás őrző eljárást; vagy

e) ha egy “hívás folyamat – csatorna-megszakítás” CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak egy “hívott bont” eseményt (BITE 25) kell az összedolgozó interfészhez továbbítani, és minden hívási tevékenységet meg kell szüntetni.

4.8.6.1.2.1.5 *GES kimenő C-csatorna-bontás őrző.* Egy földi kezdeményezésre használt C-csatorna felszabadításhoz a GES áramkör üzemmódú szolgáltatásnak a következőket kell végrehajtani, ahogy az már más helyen, a 4.8. pont ban leírásra került.

a) ha a C-csatorna légijárműtől jövő vivőfrekvencia megszűnik a hat közül utolsónak küldött “hívási folyamat – csatorna-megszakítás” CM-LIDU továbbításától számított tG17 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni; vagy

b) ha a C-csatorna légijárműtől jövő vivőfrekvenciája nem szűnik meg a hat közül utolsóként továbbított “hívás folyamat – csatorna-megszakítás” CM-LIDU elküldésétől számított tG17 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak tizenkettő “hívási folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon és egy “hívás folyamat – csatorna-megszakítás” CM-LIDU-t a P-csatornán keresztül az adatkapcsolati réteghez továbbítani. Ha a légijárműtől jövő frekvencia nincs jelen, akkor minden hívási tevékenységet meg kell szüntetnie. Ellenkező esetben, ha a C-csatorna légijárműtől jövő vivőfrekvencia megszűnik a “hívás folyamat – csatorna-megszakítás” CM-LIDU-nak a P-csatornán való továbbításától számított tG18 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetnie. Ha a C-csatorna légijárműtől jövő vivőfrekvencia nem szűnik meg ugyanazon tG18 másodperces perióduson belül, akkor a GES áramkör üzemmódú szolgáltatásnak a periódus végén minden hívási tevékenységet meg kell szüntetni.

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotát az ellenőrző funkcióhoz kell továbbítani.

c) ha egy "hívás folyamat - csatorna-megszakítás" CM-LIDU kerül vételre, akkor a GES áramkör üzemmódú szolgáltatásnak várnia kell a C-csatorna alsávnak a légijárműtől jövő megszűntetésére. Ha a légijárműtől jövő vivőcsatorna nincs jelen, akkor meg kell szűntetni minden hívási tevékenységet; ellenkező esetben, ha a "hívás folyamat - csatorna-megszakítás" CM-LIDU vétele után tG18 másodpercen belül a légijárműtől jövő C-csatorna vivőhullám megszűnik, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szűntetni. Ha a légijárműtől jövő vivőfrekvencia nem szűnik meg ezen az időponton belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet be kell fejeznie.

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotát az ellenőrző funkcióhoz kell továbbítani.

4.8.6.1.2.2 *GES beérkező áramkör üzemmódú eljárás.* Ezt az eljárást a következő egymással összefüggő eljárásoknak kell meghatározni:

a) GES bejövő áramkör üzemmódú hívás-kezdeményezés – 4.8.6.1.2.2.1;

b) GES bejövő két-irányú beállítás – 4.8.6.1.2.2.2;

c) GES bejövő C-csatorna létrehozás – 4.8.6.1.2.2.3;

d) GES bejövő földi csatorna befejezés – 4.8.6.1.2.2.4;

e) GES bejövő C-csatorna fenntartás – 4.8.6.1.2.2.5;

f) GES bejövő C-csatorna bontás őrzés – 4.8.6.1.2.2.6.

4.8.6.1.2.2.1 *GES beérkező áramkör üzemmódú hívás-kezdeményezés.* Egy egyedi alkalmazási referencia-számmal rendelkező “hozzáférési kérés – telefon” CM-LIDU egy AES-től való vételekor, a GES áramkör üzemmódú szolgáltatásnak fel kell kérnie a GES vezérlést egy C-csatorna kijelölésére, a 4-43. táblázatbeli C-csatorna Q számmal ellátott C-csatorna forrásokból.

Megjegyzés. – Ez azt jelenti, hogy a C-csatorna Q számát az adatkapcsolati rétegben lévő áramkör üzemmódú kezdeti hívás-jelzésben használt Q számból kell származtatni.

A GES áramkör üzemmódú szolgáltatásnak ezután a következőket kell végrehajtani:

a) ha egy “hívás folyamat – csatorna-megszakítás” CM-LIDU érkezik a GES vezérlés C-csatorna források kijelölését megelőzően, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni; vagy

b) ha C-csatorna források nem állnak rendelkezésre, akkor a GES áramkör üzemmódú szolgáltatásnak egy “hívási folyamat – hívási kísérlet eredménye” CM-LIDU-t kell a P-csatornán keresztül az adatkapcsolati réteghez továbbítani. Ezt követően a GES áramkör üzemmódú szolgáltatásnak tG9 másodpercet várakoznia kell az aktuális alkalmazási referencia-számmal bíró eredeti “hozzáférés kérés – telefon” CM-LIDU megismétlésének potenciális vételére. Ha egy ilyen további CM-LIDU érkezik az AES áramkör üzemmódú szolgáltatástól, akkor a GES áramkör üzemmódú szolgáltatásnak a “hívás folyamat – hívás kísérlet eredménye” CM-LIDU-t ismét továbbítania kell, ellenkező esetben a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szűntetni a kezdeti tG9 másodperces időtartam lejárta után.

Máskülönben, a GES áramkör üzemmódú szolgáltatásnak egy “C-csatorna kijelölés” CM-LIDU-t kell az adatkapcsolati réteghez továbbítani. Ezzel egyidejűleg, a GES áramkör üzemmódú szolgáltatásnak fel kell kérnie a GES vezérlést a korábban kijelölt C-csatorna egység aktivizálására. Bármely, a C-csatorna egység aktivizálását megelőzően vett (azonos alkalmazási referencia-számú) redundáns “hozzáférési kérés – telefon” CM-LIDU-t figyelmen kívül kell hagyni. Ezt követően a GES áramkör üzemmódú szolgáltatásnak végre kell hajtani a 4.8.6.1.2.2.2 pontban meghatározott GES beérkező két-irányú beállítási eljárást.

Megjegyzés. – A C-csatorna egység aktivizálását megelőzően előfordulhat redundáns "hozzáférési kérés – telefon" CM-LIDU-k vétele; az ilyen CM-LIDU AES által végzett sorozatos továbbításának eredményeként. A redundáns CM-LIDU-k következmény nélkül figyelmen kívül hagyhatók.

4.8.6.1.2.2.2 *GES bejövő két-irányú beállítás.* Ahogy az a 4.8 pontban más helyen is előírásra került, a GES áramkör üzemmódú szolgálatnak el kell végezni a "hozzáférési kérés – telefon" CM-LIDU-ban meghatározott hálózati azonosító útvonal-kiválasztás vizsgálatát, miközben ezzel egyidejűleg a következőket is teljesíti:

1. Megjegyzés. – Az útvonal-kiválasztási elemzést egy olyan GES-specifikus eljárásnak tekintjük, amelyben a hálózati azonosítót használják azon beszéd-üzemű áramkörök specifikus csoportjának azonosítására, amelyek egymással összekötik a GES-t és a megkívánt földi telepítésű áramkör kapcsolású beszéd-üzemű hálózatokat.

2. Megjegyzés. – Az ebben az al-részben szereplő logikai egység kezdeményezi a földi telepítésű hívás befejezést, miközben ezzel egyidejűleg kezdeményezi a C-csatorna létrehozását.

a) ha egy kiegészítő aktuális alkalmazási referencia-számmal bíró "hozzáférési kérés – telefon" CM-LIDU érkezik az AES áramkör üzemmódú szolgáltatástól a legutolsó "C-csatorna kijelölés"-i CM-LIDU adatkapcsolati réteghez történt továbbítását követő tG11 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak a "C-csatorna kijelölés" CM-LIDU-t ismét továbbítania kell az AES áramkör üzemmódú szolgáltatáshoz; vagy

b) ha egy "hívás-információ – szolgálati cím" CM-LIDU nem kerül vételre az utolsó "csatorna kijelölés" CM-LIDU adatkapcsolati réteghez történt továbbítását követő tG11 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak végre kell hajtani a 4.8.6.1.2.2.6 pontban meghatározott GES beérkező bontás őrző eljárást; vagy

c) ha egy "hívás folyamat – csatorna-megszakítás" CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak meg kell várni a C-csatorna légijárműtől jövő vivőfrekvencia megszűnését. Ha a légijárműtől jövő vivőfrekvencia nincs jelen, minden hívási tevékenységet meg kell szüntetnie; ellenkező esetben, ha a C-csatorna légijárműtől jövő vivőfrekvencia a "hívás folyamat – csatorna-megszakítás" CM-LIDU vételét követő tG24 másodpercen belül szűnik meg, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni. Ha a vivőfrekvencia nem szűnik meg ugyanazon tG24 másodperces perióduson belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet a periódus végén; kell megszűntetni; vagy

Megjegyzés. – Egy légijárműtől jövő nem megszüntetett frekvencia állapotát egy ellenőrző funkcióhoz kell továbbítani.

d) ha egy "hívás információ – szolgálati cím" CM-LIDU kerül vételre a C-csatorna egység aktivizálását követő tG11 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak meghatározatlan ideig minden tG10 másodpercben a "hívás folyamat – ellenőrzés" CM-LIDU-kat kell továbbítania; vagy

4) ha az útvonal-kiválasztási elemzés azt mutatja, hogy a hívás befejezése akár a GES kapcsoló-berendezésében, akár a földfelszíni hálózathoz vezető továbbító áramkör csoportban lévő torlódás miatt van blokkolva, akkor a GES áramkör üzemmódú szolgáltatásnak meg kell állítani a "hívás folyamat – ellenőrzést" CM-LIDU-k továbbítását, és azt követően hat "hívás folyamat – csatorna-megszakítás" CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez küldenie. Ezt követően a GES áramkör üzemmódú szolgáltatásnak végre kell hajtani a 4.8.6.1.2.2.6 pontban meghatározott GES bejövő bontás őrzés eljárást; vagy

f) ha az útvonal-kiválasztási elemzés sikeresen talál a földfelszíni hálózathoz egy továbbító áramkört, akkor a GES áramkör üzemmódú szolgáltatásnak egy "AMS(R)S hívás-kezdeményezés" eseményt (FITE 18) kell a földfelszíni hálózatnál lévő összedolgozó interfészhez továbbítani. Ha egy "hívási nformáció – szolgálati cím" CM-LIDU már megérkezett, akkor a GES áramkör üzemmódú szolgáltatásnak végre kell hajtani a 4.8.6.1.2.2.4 pontban meghatározott GES bejövő földfelszíni befejezési eljárást; ellenkező esetben a GES áramkör üzemmódú szolgáltatásnak várakoznia kell a 4.8.6.1.2.2.3 pontban meghatározott GES bejövő C-csatorna létrehozási eljárás végrehajtásával a C-csatorna kapcsolat létrehozására.

4.8.6.1.2.2.3 *GES bejövő C-csatorna létrehozása*. Ahogy az a 4.8 pont más alpontjaiban már előírásra került, a GES áramkör üzemmódú szolgáltatásnak a következőket kell végrehajtani, miközben várakozik a C-csatorna létrehozására:

Megjegyzés. – Ebben az al-részben lehetőség van arra, hogy jelző események kerüljenek vételre a földfelszíni hálózattól. Ezért, ha bármilyen telefon-technikai összedolgozó esemény érkezik a földfelszíni hálózatnál lévő összedolgozó interfészhez, azokat a következő al-részekben meghatározott logikai egységek általi értelmezése céljából sorrendi sorozatban kell tartani.

a) ha egy kiegészítő aktuális alkalmazási referencia-számmal bíró "hozzáférési kérés – telefon" CM-LIDU kerül vételre az AES áramkör üzemmódú szolgáltatástól, a legutolsó "C-csatorna kijelölés" CM-LIDU adatkapcsolati réteghez történt továbbítását követő tG11 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak a "C-csatorna kijelölés" CM-LIDU-t ismét továbbítani kell az AES áramkör üzemmódú szolgáltatáshoz; vagy

b) ha egy "hívás folyamat – csatorna-megszakítás" CM-LIDU érkezik a C-csatorna aktivizálását követő tG11 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak meg kell állítani a "hívás folyamat – ellenőrzés" CM-LIDU-k továbbítását, és egy "hívó bont" eseményt (FITE 22) kell küldenie az összedolgozó interfészhez. (Ha további "hívás folyamat – csatorna-megszakítás" CM-LIDU-k kerülnek vételre, akkor a GES áramkör üzemmódú szolgáltatásnak figyelmen kívül kell hagyni azokat.) Azt követően a GES áramkör üzemmódú szolgáltatásnak a "hívás folyamat – csatorna-megszakítás" CM-LIDU vételét követően tG24 másodpercet kell várakozni a C-csatorna légijárműtől jövő vivőfrekvencia megszűnésére. Ha a légijárműtől jövő vivőfrekvencia nincs jelen, minden hívási tevékenységet meg kell szüntetnie; ellenkező esetben, ha a C-csatorna légijárműtől jövő vivőfrekvencia a tG24 másodperces perióduson belül megszűnik, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetnie. Ha a légéijárműtől jövő vivőfrekvencia nem szűnik meg ugyanezen az időtartamon belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szűntetni az időtartam végén;vagy

Megjegyzés. – Egy légijárműtől jövő nem megszüntetett frekvencia állapotát egy ellenőrző funkcióhoz kell továbbítani.

c) ha nem érkezik egy "hívás információ-szolgálati cím" CM-LIDU a legutolsó "C-csatorna kijelölés" CM-LIDU-nak az adatkapcsolati réteghez történt továbbítását követő tG11 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak egy "hívó bont" eseményt (FITE 22) kell küldeni az összedolgozó interfészhez ,és végre kell hajtania 4.8.6.1.2.2.6 pontban meghatározott GES bejövő bontás őrzési eljárást; vagy

d) ha egy "hívás információ – szolgálati cím" CM-LIDU érkezik a C-csatorna egység aktivizálását követő tG11 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak meghatározatlan időn keresztül, minden tG10 másodpercben a "hívási folyamat – ellenőrzés" CM-LIDU-kat kell elküldenie, és végre kell hajtania a 4.8.6.1.2.2.4 pontban meghatározott GES beérkező földfelszíni befejezési eljárást.

4.8.6.1.2.2.4 *GES bejövő földfelszíni befejezés.* Miközben a GES áramkör üzemmódú szolgáltatás a földfelszíni hálózaton keresztül létrehozandó hívás befejezésére vár, biztosítania kell a C-csatorna egység és a földfelszíni hálózat továbbító áramköre közötti áramköri útvonalat, miközben ezzel egyidejűleg minden tG10 másodpercben egy "hívási folyamat – ellenőrzés" CM-LIDU-t továbbít az adatkapcsolati réteghez, meghatározatlan időn keresztül. Ezenkívól a következőket is el kell végeznie:

Megjegyzés. – Ezen a ponton a GES-en keresztül létrejön az áramkör folyamatosság a C-csatorna és a földfelszíni hálózati áramkör között. A hívás befejezése a hálózaton keresztül még folyamatban van és a hálózat hívási folyamatának hangjai hallhatók lehetnek a légijárművön lévő fél számára. Ha a hívott fél válaszol a hívási kisérletre, ezt a földfelszíni hálózattól érkező "válasz" esemény (BITE 22) vétele jelzi az összedolgozó interfészben.

a) ha a C-csatorna légijárműtől jövő vivőfrekvencia több mint tG13 másodpercre megszűnik, akkor a GES áramkör üzemmódú szolgáltatásnak egy "vevő bont" eseményt (FITE 22) kell az összetdolgozó interfészhez továbbítani. A FITE 22 esemény elküldése után, a GES áramkör üzemmódú szolgáltatásnak meg kell állítani a "hívás folyamat – ellelnőrzés" CM-LIDU-k küldését. Ezt követően a GES áramkör üzemmódú szolgáltatásnak hat "hívási folyamat – csatornaf-megszakítás" CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez továbbítani. Azt követően a GES áramkör üzemmódú szolgáltatásnak végre kell hajtani a 4.8.6.1.2.2.6 pontban meghatározott GES bejövő bontási őrzés eljárást; vagy

b) ha akár egy "bejövő oldal felszabadítása" esemény (BITE 29) vagy egy "sikertelen hívás" esemény (BITE 12, 14, 15, 16, 17 vagy 20) érkezik az összedolgozó interfésztől, akkor a GES áramkör üzemmódú szolgáltatásnak meg kell állítania a "hívási folyamat – ellenőrzés" CM-LIDU-k továbbítását. Ezt követően a GES áramkör üzemmódú szolgáltatásnak hat "hívás folyamat – csatorna-megszakítás" CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez továbbítani. Azt követően a GES áramkör üzemmódú szolgáltatásnak végre kell hajtani a 4.8.6.1.2.2.6 pontban meghatározott GES bejövő bontás őrzési eljárást; vagy

c) ha egy "hívás folyamat – csatorna-bontás" CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak meg kell állítani a "hívás folyamat – ellenőrzés" CM-LIDU-k továbbítását, és egy "hívó bont" eseményt (FITE 22) kell az összedolgozó interfészhez küldeni. (Ha további "hívás folyamat – csatorna-bontás" CM-LIDU-k érkeznek, a GES áramkör üzemmódú szolgáltatásnak azokat figyelmen kívül kell hagyni). Ha a légijárműtől jövő vivőfrekvencia nincs jelen, akkor minden hívási tevékenységet meg kell szüntetnie; egyébként, ha a C-csatorna légijárműtől jövő vivőfrekvencia tG14 másodpercen belül megszűnik, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetnie. Ha a C-csatorna légijárműtől jövő vivőfrekvencia nem szűnik meg ugyanezen perióduson belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni a periódus végén; vagy

Megjegyzés. – Egy légijárműtől jövő nem megszüntetett frekvencia állapotát egy ellenőrző funkcióhoz kell továbbítani.

d) ha egy "címzés befejezés" esemény (BITE 5) vagy egy "küldés befejezve" esemény (BITE 27) érkezik az összedolgozó interfészhez, akkor a GES áramkör üzemmódú szolgáltatásnak meg kell állítani a "hívás folyamat – ellenőrzés" CM-LIDU-k küldését. Ezt követően minden tG10 másodpercben egy "hívás folyamat – hívás kisérlet eredménye" CM-LIDU-t kell az adatkapcsolati réteg felé továbbítania, addig, amíg egy pozitív "telefon-technikaii nyugtázás" CM-LIDU nem érkezik. Ha a "hívás kisérlet – hívás kisérlet eredménye" CM-LIDU első továbbítását követő tG11 másodpercen belül nem érkezik pozitív "telefon-technikai nyugtázás" CM-LIDU, akkor a GES áramkör üzemmódú szolgáltatásnak egy "hívó bont" eseményt (FITE 22) kell az összedolgozó interfészhez továbbítani, hat "hívási folyamat - csatorna-megszakítás" CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez küldeni, és végre kell hajtani a 4.8.6.1.2.2.6 pontban meghatározott GES bejövő bontás őrzési eljárást, egyéb esetekben a GES áramkör üzemmódú szolgáltatásnak végre kell hajtani a 4.8.6.1.2.2.5 pontban meghatározott GES beérkező C-csatorna fenntartási eljárást; vagy

e) ha egy "válasz" esemény (BITE 22) érkezik az összedolgozó interfészhez, akkor a GES áramkör üzemmódú szolgáltatásnak meg kell állítani a "hívás folyamat – ellenőrzés" CM-LIDU-k továbbítását. Azt követően minden tG10 másodpercben egy "hívás folyamat – kapcsolás" CM-LIDU-t kell küldenie az adatkapcsolati réteghez addig, amíg egy pozitív "telefon-technikaii nyugtázás" CM-LIDU nem érkezik. Ha nem érkezik egy pozitív "telefon-technikai nyugtázás" CM-LIDU az első "hívás folyamat –

kapcsolás” CM-LIDU továbbítását követő tG11 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak egy “vhívó bont” eseményt (FITE 22) kell az összedolgozó interfésznek küldenie, hat “hívási folyamat – csatorna-bontás” CM-LIDU-t kell a C-csatorna alsávon keresztül továbbítani az adatkapcsolati réteghez, és végre kell hajtani a 4.8.6.1.2.2.6 pontban meghatározott GES bejövő bontás őrzési eljárást, ellenkező esetben, a GES áramkör üzemmódú szolgálatnak végre kell hajtani a 4.8.6.1.2.2.5 pontban meghatározott GES bejövő C-csatorna fenntartási eljárást.

4.8.6.1.2.2.5 *GES bejövő C-csatorna fenntartás.* A GES áramkör üzemmódú szolgáltatásnak biztosítani kell a végpont-végpont közötti áramkör üzemmódú kapcsolat folyamatosságát, amíg a következők valamelyike be nem következik:

a) ha egy “válasz” esemény (BITE 22) érkezik az összedolgozó interfészhez, akkor a GES áramkör üzemmódú szolgáltatásnak minden tG10 másodpercben egy “hívási folyamat – kapcsolás” CM-LIDU-t kell az adatkapcsolati réteghez továbbítani, amíg egy pozitív “telefon-technikai nyugtázás” CM-LIDU nem érkezik. Ha nem érkezik pozitív “telefon-technikai nyugtázás” CM-LIDU az első “hívási folyamat – kapcsolás” CM-LIDU továbbítását követő tG11 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak egy “hívó bont” eseményt (FITE 22) kell küldeni az összedolgozó interfészhez, hat “hívási folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez továbbítani és végre kell hajtani a 4.8.6.1.2.2.6 pontban meghatározott GES bejövő bontás őrzés eljárást. Ellenkező esetben a GES áramkör üzemmódú szolgáltatásnak biztosítani kell a végpont-végpont közötti áramkör üzemmódú kapcsolat folyamatosságát; vagy

b) ha egy “hívott bont” esemény (BITE 25) érkezik az összedolgozó interfészhez, akkor a GES áramkör üzemmódú szolgáltatásnak hat “hívás folyamat – csatornamegszakítás” CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez továbbítani. Azt követően a GES áramkör üzemmódú szolgáltatásnak végre kell hajtani a 4.8.6.1.2.2.6 pontban meghatározott GES beérkező bontási őrzés eljárást; vagy

c) ha a C-csatorna légijárműtől jövő vivőfrekvencia több mint tG13 másodpercig kimarad, akkor a GES áramkör üzemmódú szolgáltatásnak “hívó bont” eseményt (FITE 22) kell az összedolgozó interfésznek küldeni. Azt követően a GES áramkör üzemmódú szolgáltatásnak hat “hívás folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati réteghez toábbítani és végre kell hajtani a 4.8.6.1.2.2.6 pontban meghatározott GES bejövő bontás őrzési eljárást; vagy

d) ha egy “hívás folyamat – csatorna-megszakítás” CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak “hívó bont” eseményt (FITE 22) kell az összedolgozó interfészhez küldeni. (Ha további “hívás folyamat – csatorna-megszakítás” CM-LIDU-k érkeznek, akkor a GES áramkör üzemmódú szolgáltatásnak azokat figyelmen kívül kell hagyni.) Ha a légijárműtől jövő vivőfrekvencia nincs jelen, akkor minden hívási tevékenységet meg kell szüntetnie; ellenkező essetben, ha a C-csatorna légijárműtől jövő vivőfrekvencia a “hívás folyamat – csatorna-megszakítás” CM-LIDU vételét követő tG14 másodpercen belül nem szűnik meg, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni. Ha a C- csatorna légijárműtől jövő vivőfrekvencia ugyanazon tG14 másodperces perióduson belül megszűnik, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni a periódus végén.

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotát egy ellenőrző funkcióhoz kell továbbítani.

4.8.6.1.2.2.6 *GES bejövő bontás őrzés*. Egy légi kezdeményezési célra használt C-csatorna bontásához a GES áramkör üzemmódú szolgáltatásnak a következőket kell elvégezni, ahogy az a 4.8 pont szerint szükséges:

a) ha a C-csatorna légijárműtől jövő vivőfrekvencia megszűnik a hat “hívás folyamat – csatorna-megszakítás” CM-LIDU utolsó CM-LIDU-jának továbbítását követő tG12 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni; vagy

b) ha a C-csatorna légijárműtől jövő vivőfrekvencia nem szűnik meg a hat “hívás folyamat – csatorna-megszakítás” CM-LIDU utolsó CM-LIDU-jának továbbítását követő tG12 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak olyan tizenkettő “hívás folyamat – csatorna-megszakítás” CM-LIDU-t kell a C-csatorna alsávon keresztül az adatkapcsolati rétegnek továbbítani, amelyet egy a P-csatornán keresztül küldött “hívás folyamat – csatorna-megszakítás” CM-LIDU követ. Ha a légijárműtől jövő vivőfrekvencia nincs jelen, akkor minden hívási tevékenységet meg kell szüntetni. Ellenkező esetben, ha a C-csatorna légijármű felől érkező vivőfrekvencia megszűnik a P-csatornán keresztül küldött “hívás folyamat – csatorna-megszakítás” CM-LIDU továbbítását követő tG14 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni. Ha a C-csatorna légijárműtől jövő vivőfrekvencia nem szűnik meg ugyanazon tG14 másodperces perióduson belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni a periódus végén; vagy

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotát az ellenőrző funkcióhoz kell továbbítani.

c) ha egy “hívás folyamat – csatorna-megszakítás” CM-LIDU érkezik, akkor a GES áramkör üzemmódú szolgáltatásnak meg kell várnia a C-csatorna légijárműtől jövő vivőfrekvencia megszűnését. Ha a légijárműtől jövő vivőfrekvencia nincs jelen, akkor minden hívási tevékenységet meg kell szüntetnie, ellenkező esetben, ha a C-csatorna légijárműtől jövő vivőfrekvencia megszűnik a “hívás folyamat – csatorna-megszakítás” CM-LIDU vételét követő tG14 másodpercen belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni. Ha a C-csatorna légijárműtől jövő vivőfrekvencia nem szűnik meg ugyanazon tG14 másodperces perióduson belül, akkor a GES áramkör üzemmódú szolgáltatásnak minden hívási tevékenységet meg kell szüntetni a periódus végén.

Megjegyzés. – Egy légijárműtől jövő meg nem szüntetett frekvencia állapotát az ellenőrző funkcióhoz kell továbbítani.

4.8.7 Az ATS-specifikus földi telepítésű hálózatok szabványai

Megjegyzés. – A légiforgalmi beszéd-üzemű áramkörök kapcsolási és jelzési útmutató anyagát a 183. sz. ICAO Körlevél – ATS Beszéd-üzemű áramkörök – Kapcsolt hálózati tervezés, és az I. Rész A-Függeléke tartalmazza.

4.8.7.1 *Zárt felhasználói csoport.* Az AMS(R)S hangcsatornás szolgálatot, ideértve a légijárművek és földi telepítésű hálózatok összekapcsolását, egy zárt felhasználói csoportnak kell tekinteni olyan mértékben, hogy az egy nem-nyilvános biztonsági szolgáltatás, és amelyhez csak az ATS és az AOC felhasználók férnek hozzá és ezt szigorúan a biztonsági tájékoztatások továbbítására használják.

Megjegyzés. – A zárt felhasználói csoport meghatározása értelmileg magába foglalja azt, hogy érvényben van egy saját számozási terv. Egy biztonsági szolgálat telefon-technikai számozási tervének nem kell megfelelni a CCITT E. 163. Ajánlásban meghatározott nemzetközi nyilvános kapcsolt telefon-hálóat (PSTN) számozási tervére előírtaknak.

4.8.7.2 *Biztonsági földi telepítésű saját hálózatok.* A GES-nek tandemban együtt kell működnie az ATS igazgatóságok és a légijármű üzemeltetők által megvalósítható saját földi hálózatokkal. Ezeknek a hálózatoknak kell biztosítani a GES létesítmények és a megfelelő ATS, vagy légijármű üzemeltetők között az összeköttetési képességet és együtt kell működniük az itt meghatározott GES áramkör üzemmódú eljárásokkal.

4.8.7.2.1 A GES és az igazgatóságok vagy légijámű üzmeltetők közötti légiforgalmi beszéd-üzemű áramkörök kapcsolási és jelző interfészeinek használatát egyedi megállapodások alapján kell meghatározni.

4.8.7.2.1.1 **Ajánlás.** – *A földi telepítésű hálózatoknak biztosítani kell:*
a) a földi félhez való elsőbbségi hozzáférést anélkül, hogy az kedvezőtlenül befolyásolja a földi fél bármely meglévő összeköttetését;

b) automatikus visszahívás azokban az esetekben, amikor egy hívást egy foglaltsági feltétel blokkol a földi félnél;

c) kitérő útvonalak lehetősége, amikor szükséges és megvalósítható;

d) a bejövő légi kezdeményezésű hívások feladójának azonosítását, amikor megvalósítható; és

e) hívá-továbbítást, amikor szükséges és megvalósítható.

Megjegyzés. – A hívás-továbbítás biztosítja, hogy a kezelő személyzettel időszakosan el nem látott munkahelyekre irányuló hívások automatikusan átirányuljanak egy megfelelő kezelői munkahelyre.

4.8.7.2.2 A földi telepítésű hálózat által használt csengető hang jellemzőinek, a foglaltsági jelzésnek és a torlódási jelzésnek meg kell felelni az ITU CCITT E. 180. Ajánlásnak.

Megjegyzés. – Az ITU CCITT ES. 180. Ajánlás részleteit a CCITT Kék Könyv, II. Kötet – II-2 .Füzete tartalmazza.

4.8.7.3 *Egy foglalt földi félhez irányuló légi kezdeményezésű kísérletek regisztrációja.* Egy földi telepítésű hálózat vagy földi rendeltetési hely részére felajánlott összes hívás kisérletet a 4.8.3.2 pontban meghatározott elsőbbségi és előjogi szolgáltatással kell végrehajtani.

4.8.7.3.1 **Ajánlás.** – *Ha a földi félnél egy légi kezdeményezésű hívás kisérlet foglaltság miatt blokkolva van, akkor a földi felhasználó, vagy a földi hálózat által a hívás kisérlet rögzítését fenn kell tartani az eredeti légijárműnek szóló földi kezdeményezésű visszahívás céljára. A GES-től nem kell megkívánni olyan specifikus funkciók ellátását, amelyek lehetővé teszik egy blokkolt hívás kisérlet GES-vezérelt belső sorrendben való tartását későbbi szolgáltatás céljára.*

4.8.8 Telefon-technikai számozási terv

4.8.8.1 *Általános*. Az AMS(R)S áramkör üzemmódú szolgáltatás számára egy általános telefon-technikai számozási tervet kell létrehozni a földi telepítésű hálózatokkal való általános együttműködés elősegítése céljából.

4.8.8.2 LÉGIJÁRMŰ SZÁMOZÁS

4.8.8.2.1 *Specifikus követelmények.* A légijármű címzési tervben 10 számjegyből álló rögzített hosszúságú címet kell kijelölni. Minden kiosztott címnek azonos hosszúságúnak kell lenni.

4.8.8.2.2 *Címzés elemzése.* Az egyedi légijármű rendeltetési helyek számozásának tartalmazni kell a légijármű nyolc oktális számjegyben kifejezett AES azonosítóját, amelyhez kapcsolódik a decimális 00-99 közötti számozású, légijárművön lévő hívó vagy hívott terminál decimális két-számjegyes azonosítója. Az első 10 terminál címet (00 - 09) ATS alkalmazások céljára kell fenntartani.

4.8.8.2.2.1 Az AES áramkör üzemmódú szolgáltatásnak egy saját, 100 bevitelből álló terminál azonosító cím-helyet kell fenntartani, a légijárművön lévő minden AMS(R)S biztonsági terminálhoz. Ezen cím-hely használatát, szemben a nem biztonsági szolgálat által használt párhuzamos cím-helyével, a hívási kisérlethez társított elsőbbségbőll kell az AES áramkör üzemmódú szolgáltatásnak származtatni.

4.8.8.2.2.2 **Ajánlás.** – *A légijármű gyártók és az ATS igazgatóságok közötti későbbi kölcsönös egyezményeknek kell biztosítani, hogy a "00" légijármű terminál azonosító minden földi kezdeményezésű, egy légijármű felé irányuló, biztonsági hang-csatornás hívás alapértelmezésű rendeltetési helyként kerüljön kijelölésre. A fedélzeti hangfrekvenciás kezelő rendszereknek az ezen terminál azonosító felé küldött bármely beérkező híváshoz hozzá kell társítani egy megfelelő, fedélzeten rendelkezésre álló hang-csatornát (pl.: fedélzeti hangfrekvenciás panelen lévő "SATCOM 1" vagy "SATCOM 2"). A "05"–"09" terminál azonosítókat a fax-készülékek, vagy más digitális terminálok jövőbeni alkalmazására kell fenntartani.*

4.8.8.3 FÖLDI SZÁMOZÁS

4.8.8.3.1 *Földi rendeltetési hely címzés.* Amikor létezik egy, speciálisan biztonsági áramkör üzemmódú szolgáltatások támogatására tervezett saját hálózat, akkor az összes földi címnek 10 számjegy hosszúságúnak kell lenni. Más esetekben a biztonsági hívások földi címei változó hosszúságúak, és összhangban kell lenniük annak a hálózatnak a számozási tervével, amely hálózathoz a hívás irányul.

4.8.8.3.1.1 *Címzés elemzés.* Amikor létezik egy speciálisan biztonsági áramkör üzemmódú szolgáltatások támogatására tervezett saját hálózat, akkor az egyedi földi rendeltetési helyek számozásának a következő számjegy sorozatból kell állnia:
a) egy "8"-as számjegy;

b) a rendeltetési Államot jelölő három számjegyből álló országkód;

c) egy három-számjegyes szolgáltatás kód, amely a rendeltetési Államban lévő rendeltetési létesítményt jelöli. Egy Államon belül az egyedi létesítményeknek kijelölendő kód értékeket a rendeltetési Állam igazgatóságának kell meghatározni és közzétenni; és
d) egy három-számjegyes ügynökség kód, amely a rendeltetési létesítményben lévő rendeltetési ügynökséget jelöli. Egy létesítményen belül az egyedi ügynökségeknek kiosztandó kód értékeket a létesítményt ellenőrző szervezeti entitásnak kell meghatározni és közzétenni.

1. Megjegyzés. – A GES-től nem követelik meg egy légi kezdeményezésű AMS(R)S hívás időtartama alatt vett egyetlen földi cím konvertálását sem. A földi telepítésű hálózat bármely címet átkonvertálhat - ha szükséges - a hálózat számára megkövetelt címre.

2. Megjegyzés. – A GES üzemeltetők a hálózat üzemeltetőjével kötött egyezmény alapján átkonvertálhatnak egy földi címet egy földi hálózat által megkövetelt címre.

3. Megjegyzés. – Az ország kódok az ITU Nemzetközi Rádió-Szabályzat 43. Függeléke 1. Táblázata szerinti ITU ország kódok alapján kerültek meghatározásra. Ugyanakkor, országonként csak egy kód használható az AMS(R)S szolgálat biztonsági és szabályozó kommunikáció számára.

4.8.8.3.2 *Hálózati azonosító.* A "10-es" hálózati azonosítót kell alkalmazni minden légi kezdeményezésű biztonsági hívásban, amelyek egy speciálisan biztonsági áramkör üzemmódú szolgáltatások támogatására tervezett saját hálózathoz irányulnak.

Megjegyzés. – A GES üzemeltetők, valamint az érintett ATS igazgatóságok és légijármű üzemeltetők közötti előzetes egyezmény alapján kiegészítő hálózati azonosítók alkalmazhatók a biztonsági összeköttetések esetében.

4.9 LÉGIJÁRMŰ FEDÉLZETÉN ELHELYEZETT FÖLDI ÁLLOMÁS (AES) KEZELÉSE

4.9.1 Általános

Az AES kezelési funkcióknak tartalmazni kell az AES-ben végrehajtott funkciókat egy bejelentkezési folyamat kezdeményezésére és végrehajtására, egy bejelentkezési állapot fenntartására, egy kijelentkezési folyamat kezdeményezésére és végrehajtására, valamint egy GES-sel való adat- és beszéd-összeköttetés kezelésére.

4.9.2 AES kezelési interfészek

4.9.2.1 Az AES kezelésnek a következő AES entitások számára kell interfészeket biztosítania:

a) al-hálózati réteg;
b) adatkapcsolati réteg;
c) fizikai réteg;
d) áramkör üzemmódú szolgáltatás.

4.9.2.1.1 *AL-HÁLÓZATI RÉTEG*

Az AES kezelés és az al-hálózati réteg között kicserélt információknak a következőket kell tartalmazni az al-réteg felé:

1) bejelentkezési állapot: bejelentkezés, kezdeti vagy megújított/kijelentkezett;

2) bejelentkezési GES azonosító (ha be volt jelentkezve);

3) AES azonosító.

4.9.2.1.2 *ADATKAPCSOLATI RÉTEG*

Az AES kezelés és az adatkapcsolati réteg között kicserélt információknak a 4.5.2 pontban leírt adatkapcsolati réteg adat egység (LIDU) formáját kell öltenie. Az ezen interfészen keresztül kicserélt összes LIDU-nak a 4-44. táblázatban meghatározottak szerintinek kell lenni, azon kivétellel, hogy az AES vezérléshez küldött információknak is tartalmazni kell olyan interfész kezelő információt, ami az AES kezelést egy R-csatorna véletlenszerű kiválasztására utasítja.

Megjegyzés. – Az adatkapcsolati réteg a jel egységeket a vett LIDU-kban lévő információknak megfelelően állítja össze. A LIDU formátumok nincsenek előírva. A jel egység formátumai a 4. Fejezet 2. Függelékében találhatók.

4.9.2.1.3 *FIZIKAI RÉTEG*

Az AES kezelése és a fizikai réteg között kicserélt információnak a következőket kell tartalmazni:
a) a fizikai réteg felé:
1) Az adó- és a vevő-csatorna egységek frekvenciái;

2) csatorna egység mód-kiválasztás (R-, T- vagy C-csatorna);

3) csatornaátviteli sebesség;

4) adó-teljesítmény beállítások;

5) csatorna egység száma;

b) a fizikai réteg felől:

1) P-csatorna veszteség/teljesítmény-csökkenés jelzése,

2) P-csatorna szinkronizáció jelzése;

3) minden egyes, C-csatornát vevő csatorna egység számított bit-hiba aránya..

4.9.2.1.4 *ÁRAMKÖR ÜZEMMÓDÚ SZOLGÁLTATÁS*

Az AES kezelése és az áramkör üzemmódú szolgáltatás közötti információknak a következőket kell tartalmazni:

a) az áramkör üzemmódú szolgáltatás felé:

1) bejelentkezési állapot, (vagyis bejelentkezett/kijelentkezett);

2) bejelentkezési GES azonosító;

3) csatorna egység száma, a csatorna egység kijelölés számára válaszul minden egyes kérésre;

b) az áramkör üzemmódú szolgáltatás felől:

1) egy adó-csatorna egység és társított Q-szám kijelölésére szóló kérés, alkalmazási referencia-szám, frekvencia, csatorna-átviteli sebesség és kezdő EIRP;

2) egy vevő-csatorna egység és társított Q-szám kijelölésére szóló kérés, alkalmazási referencia-szám, frekvencia és csatorna-átviteli sebesség;

3) egy R-csatorna véletlenszerű kiválasztására szóló parancs.

4.9.3 AES kezelési funkciók

4.9.3.1 Az AES kezelésnek a következő funkciókat kell végrehajtania:

a) AES táblázat-kezelés;

b) AES bejelentkezési állapot kezelés;

c) AES csatorna-kezelés.

4.9.3.2 AES TÁBLÁZAT-KEZELÉS

4.9.3.2.1 Az AES táblázat-kezelésnek a következő két táblázatot kell fenntartania:

a) rendszer táblázat;

b) bejelentkezés-megerősítő tábla.

4.9.3.2.2 *RENDSZER TÁBLÁZAT*

A műholdas szolgáltatási területen belül ennek a táblázatnak a tartalmát minden egyes sugárnyaláb esetében a GES által biztosítani kell (lásd 4.10.4.2.2).

4.9.3.2.3 *AES RENDSZER TÁBLÁZAT FELFRISSÍTÉS*

A rendszertáblázatok tartalmának felfrissítése céljából az AES kezelésnek a következő eljárásokat kell alkalmazni:

a) *A bejelentkezést megelőzően.* Miután az AES kezelés egy műhold/sugárnyaláb-azonosító P_{smc} frekvencián egy adás-sorozatot vesz, meg kell határoznia, hogy a vett sorozat rész- vagy teljes sorozat (lásd
4.10.4.5.2) és azt követően a következőket kell tenni:

1) ha egy rész-sorozat, akkor a vett rész-sorozatban meghatározott helyesbítő számot az AES kezelésnek össze kell hasonlítania a rendszer táblázatban lévő megfelelő aktuális adatszegmens helyesbítő számával. Ha a vett helyesbítő szám eggyel nagyobb az aktuáliss számnál, akkor az AES-nek a vett sorozatnak megfelelően fel kell frissíteni a rendszer táblázatát. Ha a vett helyesbítő sorozat egy teljes sorozat, akkor az AES-nek a rendszer táblázatát annak megfelelően kell felfrissíteni.

2) ha a vett sorozat egy teljes sorozat, akkor az AES-nek a rendszer táblázatát annak megfelelően kell frissíteni.

b) *Bejelentkezés után.* Amikor az AES egy rész-sorozatot vesz a bejelentkezett GES-től, akkor annak megfeleleően fel kell frissítenie a rendszer táblázatát.

4.9.3.2.4 *BEJELENTKEZÉS MEGERŐSÍTŐ TÁBLÁZAT*

Ennek a táblázatnak a következőket kell tartalmazni:

a) műhold azonosító;

b) sugárnyaláb azonosító;

c) bejelentkezés GES azonosító;

d) kezdeti EIRP az R-csatornák részére;

e) P_d csatorna frekvencia és csatorna átviteli sebesség;

f) R_d csatorna frekvenciák és csatorna átviteli sebesség;

g) T-csatorna frekvenciák és csatorna átviteli sebesség;

h) az AES által egyidejűleg támogatható C-csatornák száma (beleértve egy C-csatornát, amely olyan adót
használ, amelyet a 3. Szintű AES C-, R- és T-csatornák megosztottan használnak).

4.9.3.2.5 *BEJELENTKEZÉS MEGERŐSÍTŐ TÁBLÁZAT FELFRISSÍTÉS*

A bejelentkezési megerősítő táblázat tartalmát, a h) bekezdés kivételével, akkor kell felfrissíteni, amikor az AES kezelés bejelentkezik, megújítja bejelentkezését, vagy befejez egy adatcsatorna újra-kijelölési eljárást a GES-nél (4.9.3.3.4.1 f).)

4.9.3.3 AES BEJELENTKEZÉS ÁLLAPOT KEZELÉS

4.9.3.3.1 Mielőtt egy AES megkezdi a felhasználói összeköttetés szolgáltatás biztosítását, az AES kezelésnek sikeresen be kell fejeznie a 4.9.3.3.4 pontban megadott bejelentkezési eljárást egy kiválasztott GES-nél. A bejelentkezési eljárás kezdeményezését megelőzően az AES kezelésnek a 4.9.3.3.2 pont szerint ki kell választani egy alkalmas műhold, sugárnyaláb és GES kombinációt.

4.9.3.3.2 *MŰHOLD, SUGÁRNYALÁB ÉS GES KIVÁLASZTÁS*
